If the present results are compared with similar data collected from the Heron Island locality by Weber and Woodhead[8], the values for the oxygen isotope ratios are 1‰ lighter. This apparent discrepancy may be a result of preparation procedure, as Weber and Woodhead[8] removed the organic material from their corals using the helium treatment; however, this should have made their corals lighter than ours, they are in fact heavier. Either there has been a drastic change in the prevalent environmental conditions or there are differences in the analytical techniques. Another possible source of contamination is subsequent diagenesis, either through isotopic exchange or the activities of endoliths such as fungi, algae and bacteria: boring filaments are known to infest coral skeletons within hours of it being formed[23]. Clearly it is practically impossible to eliminate all subsequent diagenetic affects. Sampling the growth bands within coral heads therefore will include the products of a wide range of diagenetic processes in the sampled carbonate; this is particularly relevant to the denser bands, which coincide with green algal bands often seen when a coral head is broken open[24].

Isotopic data obtained from all marine organisms must be interpreted with extreme caution. There are too many uncertainties concerning the controlling processes in modern calcareous organisms, without considering subsequent diagenetic effects. The reasons for the lack of differences in the skeletal $\delta^{18}O$ value between the various habitats in the present research, despite the large temperature differences, is probably a result of either or both of the following factors: (1) The variation in the seawater $\delta^{18}O$ alone would be sufficient to mask an actual temperature difference of 7 °C; however, as the $\delta^{18}O$ of seawater may vary sympathetically with temperature, an even greater temperature difference may be masked. (2) An increase in temperature increases the metabolic processes of the coral and therefore alters the proportions of oxygen and carbon incorporated from the various organic and inorganic sources proposed by Weber and Woodhead[8] and Goreau[6]. According to Goreau[6] an increase in growth rate increases the isotopically heavier inorganic component incorporated. This effectively cancels out the temperature dependence of the $\delta^{18}O$ value. As the $\delta^{13}C$ is only slightly temperature dependent, this change in growth rate is reflected in the carbon isotope composition.

We thank the staffs of Heron Island Research Station and Kings College London for their help, Dr J. A. E. B. Hubbard for her advice and the Director of the Institute of Geological Sciences for permision to publish the data. This research was made possible by the awarding of a grant to P.K.S. by the NERC.

Thermal effects of basalt on continental crust and crustal contamination of magmas

P. J. Patchett*

Department of Geology and Mineralogy,
Parks Road, Oxford, UK

A simple conduction-based heat-flow model is used to calculate the thickness of zones of continental crustal rock adjacent to basalt sheets which are raised to the temperatures of (1) hydrous mineral breakdown and (2) partial melting. Basalt emplacement leads to wide zones of partial fusion and aqueous fluid circulation at most crustal levels. Contamination of the basalt magma by partial melts or aqueous fluids is most effective where magmatism is episodic and repetitive on a 0.1–1,000 yr time scale.

Table 1 Thermal properties and symbols

Property	Symbol	Value assumed
Distance	x	
Time	t	
Temperature	T	
Crustal rocks		
Density	ρ	$2.7\ \mathrm{g\ cm^{-3}}$
Heat capacity	C	$840\ \mathrm{J\ kg^{-1}\ K^{-1}}$
Thermal conductivity	K	$2.5\ \mathrm{W\ m^{-1}\ K^{-1}}$
Initial thermal gradient		$15\ \mathrm{K\ km^{-1}}$ (Fig. 1)
*Basalt magma**		
Latent heat of fusion†	L	$420\ \mathrm{kJ\ kg^{-1}}$
Liquidus T	T_{liq}	1200 °C (1,473 K)
Solidus T	T_{sol}	900 °C (1,173 K)
Volume fraction crystallised‡	V	

* Basalt was taken to have the same density, heat capacity and thermal conductivity as the crustal rocks; this has very little effect on the results.

† Crystallisation was assumed linear with temperature, and latent heat assumed to be liberated uniformly between liquidus and solidus temperatures.

‡ As a result of the above assumption derivative $\partial V/\partial t$ is obtained by the substitution $\partial V/\partial t = \partial T/\partial t \cdot 1/(T_{\mathrm{liq}} - T_{\mathrm{sol}})$ (see ref. 1).

The thermal calculations were performed using a program written by Wells[1] to solve by an implicit Crank–Nicolson finite difference method the one-dimensional equation

$$\frac{\partial T}{\partial t} = \frac{K}{\rho C} \cdot \frac{\partial^2 T}{\partial x^2} + \frac{L}{C} \cdot \frac{\partial V}{\partial t}$$

Symbols and assumed values for parameters are given in Table 1. This simplification of the full equation given in ref. 1 arises because radiogenic heat production is ignored, and the thermal conductivity treated as constant. The principles, and results, do not differ materially from those given by Jaeger[2], except that initial crustal temperature and its effect on the rate of heat transfer are taken into account.

Basalt sheets in any orientation are emplaced into the crust as a single pulse of magma. The heat flow equation is solved at right angles to these infinitely extensive sheets. Two thermal effects are considered:

(A) Aqueous fluid circulation in the crustal rock. Where a free fluid phase is present, it will move in response to the thermal gradient. Where there is no initial free fluid phase, H_2O movement will begin when hydrous minerals break down. The stability limits for common hydrous minerals are shown in Fig. 1. The zones of country rock raised above the breakdown temperatures of muscovite and biotite in the absence of quartz are shown in Fig. 2.

(B) Partial melting of the crustal rock. Almost all crustal rocks containing a free fluid phase can yield some partial melt at the H_2O-saturated granite minimum (Fig. 1)[3]. The zone of country rock heated above this curve is shown in Fig. 2. Where there is no free fluid phase, melting begins at hydrous mineral breakdown[3]. Therefore the probable zone of partial melting, shaded in Fig. 2, is bounded by the granite minimum to ~4 km, and by the breakdown of biotite below that depth. Movement of aqueous fluids and production of felsic partial melts must be real effects physically distinct from each other because there is a wide solubility gap between H_2O and silicate melt, spanning 70% of the compositional range even at 30 km depth[4].

The thermal model used may yield minimum estimates for the zones of crust affected by partial melting and fluid movement because:

(1) Flow of magma through the fissure will increase the overall heat input to the country rock.

(2) The calculations are based only on heat conduction, and heat transfer by convection in the magma and by circulating fluids in the crustal rocks will speed up the heat flow.

(3) At least in the upper crust, there is likely to be a free fluid phase. This will extend the zone of partial melting, and will be mobilised over a much greater width than the zone of hydrous mineral breakdown.

On the other hand, the estimates may be maxima because:

(4) If magmas rise through pipes rather than fissures, initial effects on crustal rocks will be unchanged, but the heated zones will later be narrower and shorter-lived.

(5) The circulation of fluids may have the effect of dissipating the heat quite rapidly, so that there is a very wide zone affected by fluids, but only a narrow partially fused zone.

(6) Many lower crustal regions may consist of granulite facies rocks, containing neither a free fluid phase nor significant hydrous minerals. Such rocks may not melt until 1,000 °C, and both melting and fluid phase circulation would be essentially absent. The dotted lines below 20 km in Fig. 2 reflect this uncertainty, but it is significant that high electrical conductivity in the lower crust of two areas, both in high-grade metamorphic regions, necessitate the presence of considerable pore water[5,6].

(7) Absorption of latent heat of fusion by the crustal rock is not taken into account, as it is difficult to estimate the degree of partial melting. Partial fusion of 50% over a zone results in a ~30% reduction of zone width as compared to Fig. 2, while 10% partial fusion leads to only ~8% width reduction. The effects are clearly marginal to the general model discussed here.

(8) If the hydrous phase in the crustal rocks is hornblende rather than sheet silicates, the breakdown zone will be narrower than that shown in Fig. 2, and in some cases absent.

Combining all these points suggests that the magnitude of the effects shown in Fig. 2 is probably realistic. The greatest uncertainty is in the lower crust.

Figure 2 emphasises the fact that in the uppermost crust, aqueous fluid circulation is the dominant effect of magma emplacement. At this level, partial melting does not occur due to the high temperature of granite minimum melting (Fig. 1). As hydrous mineral breakdown temperatures are very conservative indicators of the beginning of fluid circulation, the actual width affected by fluids in the upper 10 km will probably be at least double that shown. Norton and Taylor[20] have modelled such high-level effects in detail.

Figure 2 also demonstrates clearly that the basalt causes considerable partial melting of the crustal rocks at most depths. After an appropriate lapse of time, basalt sheets at 10 km depth for example, can develop partially molten zones of country rock equal to 10–20% of their own thickness. Less than 1 yr is

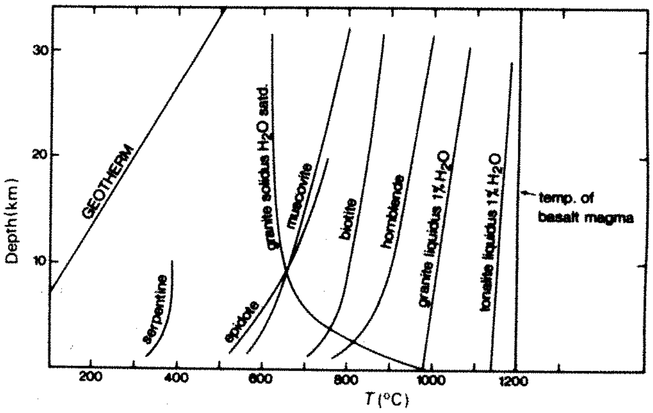

Fig. 1 The *P–T* equilibria relevant to emplacement of basalt magma into continental crust. The initial geotherm used is shown. Melting curves are from Wyllie[3]; serpentine breakdown from Johannes[16]; epidote breakdown under the haematite–magnetite buffer from Liou[17]; muscovite in the absence of quartz from Chatterjee and Johannes[18]; biotite (15% annite molecule, haematite-magnetite, quartz absent) from Wones and Eugster[19]; approximate hornblende curve from Wyllie[3]. Quartz absent reactions are used because there is probably insufficient time for minerals to interact; any other assumption leads to breakdown at lower temperature.

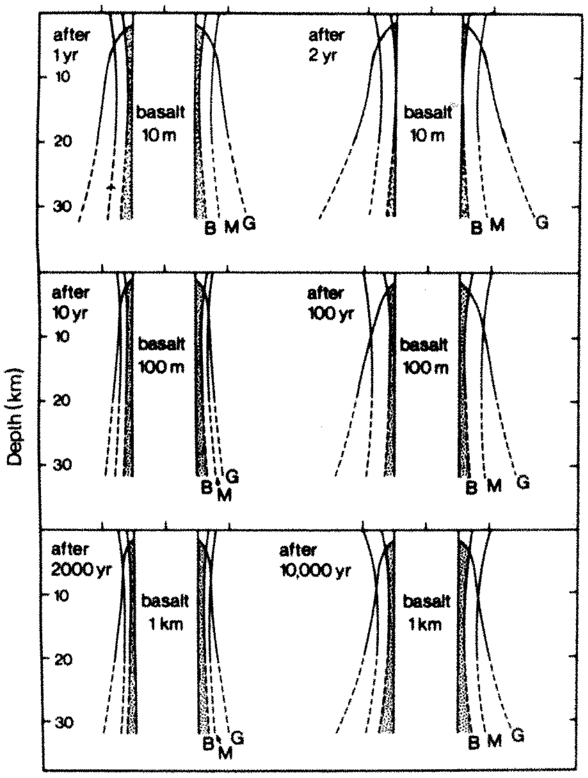

Fig. 2 The approximate temperature zones above biotite breakdown (limited by line B), muscovite breakdown (M) and the Ab–Or–Qz–V minimum melting (G) for basalt sheets 10, 100 and 1,000 m thick at 0–30 km depth. Dotting of lines below 20 km reflects uncertain H_2O and hydrous mineral content of lower crust. Shaded: the probable minimum limit of partial melting adjacent to the basalt.

required for this to be achieved around a 10 m basalt sheet, 10 yr for a 100 m sheet, and as much as 2,000 yr for a 1,000 m sheet. The upper example in Fig. 2 shows that any basalt sheet $\geqslant$10 m thick at 10 km depth develops partially molten zones $\geqslant$1 m on either side after <1 yr; clearly, some contamination of a magma by partial melts (or aqueous fluids) could take place if it flowed through its conduit for only a few weeks.

Total melting of the crust is possible only over a very short distance adjacent to the basalt, if at all. This is because while the first partial melts may be H_2O-saturated, the overall H_2O content of the crustal rock is unlikely to be >1% (ref. 4), so that its liquidus temperature will be >1,000 °C (Fig. 1)[3]. Melts can be produced over a wide zone, but they are always partial melts.

The present study emphasises the expected widespread nature of partial melting and aqueous fluid circulation near to mafic magma conduits. These selective mechanisms (see also refs 7–9 among many others) are inherently more probable for contamination of mafic magmas than bulk assimilation (compare, for example, ref. 10). Some studies[8,11–13] have shown that crystal–liquid or crystal–aqueous fluid isotopic disequilibrium occurs in the crust over the time scale required for contamination. This implies that the isotopic composition of partial melts and fluids generated in the crust cannot necessarily be predicted from the bulk composition of the crustal source rocks (compare ref. 14). Partial melts and aqueous fluids could easily be richer in ^{87}Sr for example, than the bulk crustal source rocks, because of preferential participation of Rb-rich, Sr-poor phases in the breakdown and melting reactions, and lack of time for complete fluid–residuum or melt–residuum equilibration. Such Sr diffusion data as exists[15] suggests that 5 mm feldspars could remain out of isotopic equilibrium with a crustal melt for 10^3 years or more, considerably greater than the time scale envisaged for production of crustal partial melts or active fluids and their assimilation into the mafic magma. The geochemical patterns resulting from addition to the basalt magma of contaminants which are isotopically unrepresentative of their source rocks may be highly complex. Also, as a magma may undergo contamination at several stages of its passage through the crust, no single mixing relationship is expected.

A feature of Fig. 2 is the length of time for which crustal partial melts and active aqueous fluids persist after basalt intrusion. This may be important because the major barrier to be overcome in contamination via partial melt or fluid phases is penetration through the basalt chill. In a crust which fractures to permit magma intrusion through conduits and fissures, it is unlikely that chills could remain unbroken, because further fracture must often occur after an initial magma route is established, either to admit additional dykes/conduits, or to allow increased flow through those existing. Probably the most favourable situation for contamination to occur is where magmatic pulses follow each other at intervals through the same zone of crust; say every 10–300 years for 100 m fissures. There is then a reasonable chance that new batches of magma will intrude through the heated, mechanically weakened crust adjacent to earlier largely solidified conduits, and assimilate any partial melts and hot fluids that are present. It is a common observation that igneous activity, intrusive or extrusive, is an episodic and repetitive process.

I thank S. W. Richardson, S. Moorbath, K. G. Cox and A. P. Dickin for useful discussions. P. R. A. Wells made the heat flow program available, and R. Exley provided advice on computing.

Early development of Tethys and Jurassic ophiolite displacement

S. J. Haynes

Department of Geological Sciences, Brock University, St Catharines, Ontario, Canada

P. H. Reynolds

Departments of Physics and Geology, Dalhousie University, Halifax, Nova Scotia, Canada

Previous tectonic reconstructions of the Iranian segment[1–4] of eastern Tethys have assumed that the stratigraphic positions of ophiolites from Zagros (late Cretaceous) and Makran (early Tertiary) represent the time of initial oceanic plate displacement. We present ^{40}Ar–^{39}Ar age spectra for mineral separates from metamorphic assemblages associated with the ophiolites of the eastern Zagros and the western Makran, Iran. One of the Zagros samples is from an amphibolite associated with metamorphosed basic and ultrabasic rocks while the other is from metamorphic olistolith within radiolarites, south of the main Zagros ophiolite body. The Makran sample is from a block of amphibolite contained within metamorphosed harzburgites.

0028–0836/80/060561—03$01.00

The apparent ages suggest that initial oceanic plate disruption and tectonic emplacement of the Zagros and Makran ophiolites occurred in the middle Jurassic (~170 Myr ago) with further displacements in the late Cretaceous (~97 Myr and ~89 Myr ago). The similarity of the Jurassic age with ophiolite emplacement ages in Yugoslavia[5] and Greece[6] is possible evidence of a middle Jurassic collision of an early Mesozoic Tethyan ridge system with both eastern Europe and central Asia.

In the Neyriz sector of the Zagros, two distinct metamorphic regimes[7] are separated by the Cheshmeh Anjir fault (Fig. 1). North of this fault, late Jurassic–early Cretaceous plutonism and Abukuma-type metamorphism prevail. These are probably related to ascent of thermal flux derived from a descending lithospheric plate[7]. The region south of the fault comprises thrust slices of mixed lithology that contain metamorphosed basic and ultrabasic rocks, and widespread Barrovian-type metamorphic assemblages. In a previous study of this area[7], amphibolites associated with metamorphosed ophiolite assemblages (including spilitic pillow lavas) yielded K–Ar ages of ~170±8 Myr and ~89 ±7 Myr (Fig. 1). These ages were considered minimum values, and a Triassic age of metamorphism was favoured.

The ^{40}Ar–^{39}Ar age spectrum obtained in the present study for biotite from a garnet amphibolite assemblage (H83, Table 1) is presented in Fig. 2. An apparent age plateau was not obtained for this sample. The suggestion of a low age 'saddle' in the intermediate temperature region of the spectrum is indicative of thermal alteration[8,9]. The high temperature age, ~87 Myr, although properly interpreted as a minimum value, is probably close to the true age. The similarity between this and Adib's[7] 89-Myr hornblende value, above, suggests that a distinct metamorphic event occured at this time. Age spectra for biotite and muscovite from psammitic layers in an olistolith (H86, Table 1) are shown in Fig. 2*b*. The spectra are both essentially flat over >90% of the gas release; however, small differences in apparent age (±~1%) are analytically distinguishable. The platform values for biotite and muscovite are respectively 98±1.2 Myr and 96±1.3 Myr. This suggests that a second discrete period of Upper Cretaceous metamorphism occurred at the Iranian plate margin ~97 Myr ago. It confirms a syn- or post-Cenomanian age of emplacement for the main Zagros ophiolite, an event which may have been as late as the early Maestrichtian[2]. Hornblende from an amphibolite enclosed by ultramafic rocks of the western Makran ophiolite (HB1, Table 1) gave a flat ^{40}Ar–^{39}Ar age spectrum within the limits of analytical error (Fig. 2*c*). The plateau age, 170±5 Myr, is middle Jurassic. The final emplacement age of the western Makran ophiolite is uncertain[10] but Falcon[11] has presented evidence for late Cretaceous movements that could be related to ophiolite emplacement and exhumation. During the late Cretaceous–early Tertiary the western Makran ophiolites were displaced southwards from the Zagros along the Zendan fault (Fig. 1), which at that time may have been a transform[12]. The present north-northwest structures in the western Makran (including the ophiolites) were the result of compression and overthrusting from the east along the Zendan Line in the Mio-Pliocene[12]. Adib[7] reports a K–Ar hornblende age of 170±8 Myr for a garnet amphibolite from the Neyriz sector of the Zagros, immediately south of the Cheshmeh Anjir fault (Fig. 1). The agreement between this age and our hornblende age (HB1 Fig. 1) from the western Makran amphibolite indicates that a major middle Jurassic metamorphic/tectonic event affected both the Makran and the Zagros.

Table 1 Sample locations and descriptions

Sample	Locality	Description
H83	Kuh-e Ceghalatun ~10 km south of Gouri, Zagros	Biotite schist layer in garnet amphibolite sequence. Overlain by recrystallised dolomitic marbles. Amphibolite cut by metamorphosed basic and ultrabasic rocks. 7 km west of 89±7 hornblende K–Ar locality where spilitic pillow lavas occur[7].
H86	~8 km west of Neyriz, Zagros	Olistolith of metamorphic rock in radiolarities of the Coloured Series 4 km south-west of the thrust contact of the main Zagros ophiolite body[2]. Olistolith comprises bands of psammites (muscovite, biotite, epidote and piedmontite layers), epidote calc-schists and epidote amphibolites.
HB1	~35 km north-east of Minab, Makran	Amphibolite in contact with serpentised harzburgites and serpentinites of Makran ophiolite. Hornblende, plagioclase with minor biotite. Displays strong lineation parallel to contact. Parallelism of fracture cleavage in serpentinites to contact suggests a thrust relationship.

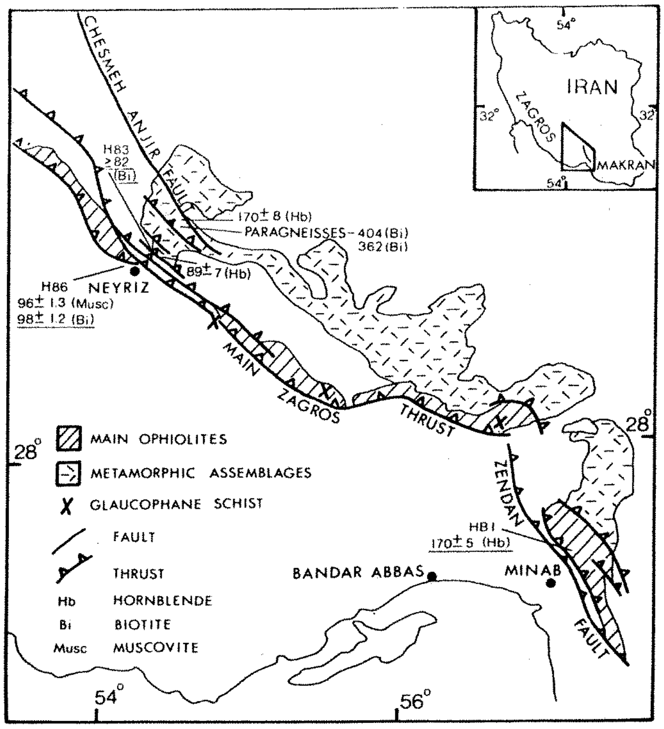

Fig. 1 ^{40}Ar–^{39}Ar ages (underlined) with published K–Ar ages[7] of metamorphic assemblages in ophiolite-bearing thrust slices of the eastern Zagros and western Makran.

Tectonic emplacement models must explain the irregular distribution of amphibolites and Barrovian-type metamorphic assemblages associated with the Zagros and Makran ophiolites which are themselves deformed/metamorphosed (serpentine, rodingites, talc), and their emplacement in a sequence of high-angle thrust slices. We postulate that Barrovian type metamorphic assemblages of the Zagros and Makran result from the frictional heating/pressure effects created during descent of subducting oceanic crust beneath a continental margin; and that spatial relationships of metamorphic facies to the descending plate/continental margin are similar to those proposed by

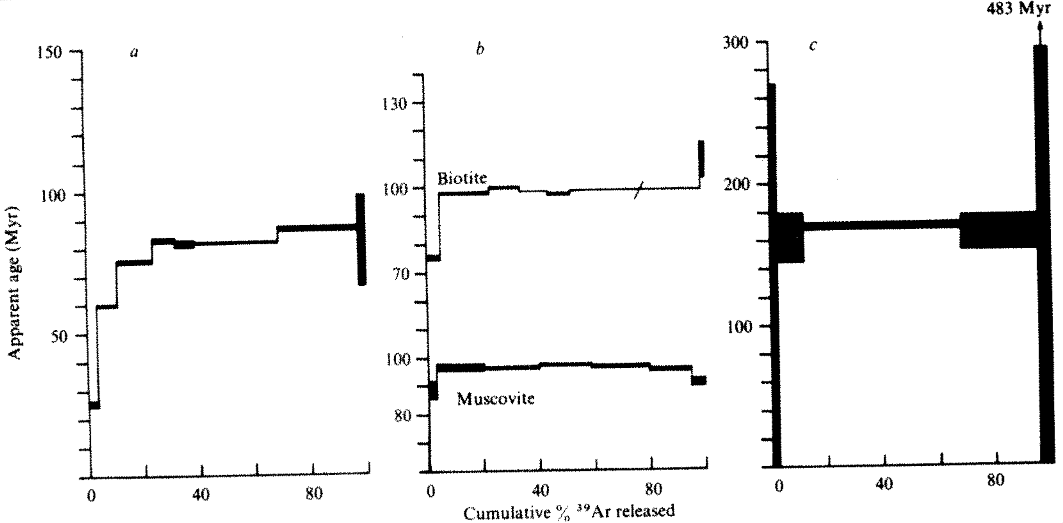

Fig. 2 Age spectra for: *a*, sample H83 biotite; *b*, H86 biotite and muscovite (the small diagonal slash separates two gas fractions); *c*, HB1 hornblende. Half-heights of black bars represent the 2σ relative (between-step) uncertainties. Decay and isotopic constants are those suggested by Steiger and Jäger[14]. Analytical procedures have been described elsewhere[15].

Ernst[13]. Thus, the middle Jurassic (~170 Myr) ages of metamorphism represent the time of initial disruption, uplift and cooling of Barrovian assemblages associated with oceanic crust. In the eastern Zagros younger slices of disrupted oceanic plate and associated metamorphic assemblages were uncoupled and emplaced to the south probably in at least two (at ~97 Myr and ~89 Myr), and possibly more, periods during the Upper Cretaceous. Further work in the western Makran may also reveal similar discrete late Cretaceous episodes. A consequence of our model is that the ophiolite assemblages are now observed as 'cold' intrusions, thrust into supra-oceanic plate continental rise/slope sediments. Because the metamorphism occurred only at/above the subducting oceanic plate which then cooled during its ascent after disruption and uncoupling this final emplacement was terminated in the Zagros and Makran by the close of the Cretaceous period, although the position of the western Makran ophiolites seems to be modified by the Mio-Pliocene westward overthrusting along the Zendan fault. Blueschist facies metamorphism has not been reported in the Neyriz and Minab sectors but glaucophane schists[7] are present in the most southerly (youngest?) thrust slices of the intervening area (Fig. 1). Glaucophane schists may be absent from the oldest (middle Jurassic) thrust slices because these slices contain continental basement assemblages having minimum Devonian, or older, K-Ar ages[7] indicating that these thrusts were located on the Iranian continental margin side of Ernst's[13] zone of blueschist metamorphism.

Amphibolites intimately associated with the ophiolites of eastern Iran, Greece[6] and Yugoslavia[5] all have remarkably similar (middle Jurassic) ages. We believe that this and the evidence for Permo-Triassic rifting in both Greece[6] and south-eastern Iran[10,16] are tectonically significant. The simplest, but not necessarily the only, explanation is to suggest essentially simultaneous middle Jurassic collision of an early Mesozoic Tethyan spreading centre (ridge) with both Europe and central Asia.

Financial support was provided by the Natural Science and Engineering Research Council of Canada. Sample irradiations were performed in the McMaster University nuclear reactor.

The ecological significance of solar UV radiation on aquatic organisms

John Calkins

Department of Radiation Medicine, University of Kentucky, Lexington, Kentucky 40536

Thorunn Thordardottir

Marine Research Institute, Reykjavik, Iceland

Stratospheric ozone shields the Earth from much of the solar UV–B radiation which is the most biologically injurious component of sunlight. It is possible that both human technologies and natural events, such as reversal of the Earth's magnetic polarity, might lead to significant ozone reductions. The methodology of evaluation of the impact of an agent such as solar UV on organisms or ecosystems has not been firmly established and there has been little research in this area in the past. A new approach is proposed here. If solar UV were an important injurious factor in nature, then living organisms would be required to expend energy to cope with the solar UV exposure they receive. If organisms must specifically mitigate solar UV injury, then it would be expected that only a minimal tolerance would be achieved. We have quantitatively estimated exposure and tolerance of a number of aquatic organisms and find them to be remarkably similar.

Comparison of solar UV effects at high and low latitudes offers opportunities for analysing solar UV as an environmental agent. The visible component of sunlight is not greatly attenuated regardless of the thickness of the atmosphere penetrated, but the UV portion, especially the shorter and more biologically injurious UV–B wavelengths ($\lambda = 280$–320 nm) are strongly absorbed by stratospheric ozone and thus will be highly dependent on the solar angle. Summer solar irradiance reaching Reykjavik (≈ 650 cal cm^{-2} deg^{-1}) approximates the energy reaching temperate or tropical regions. The UV–B radiation at Reykjavik, however, is about half the maximum daily amount reaching temperate and about 40% of that reaching tropical areas. Seasonal effects on UV–B are also much greater at high latitudes.

0028–0836/80/060563—04$01.00

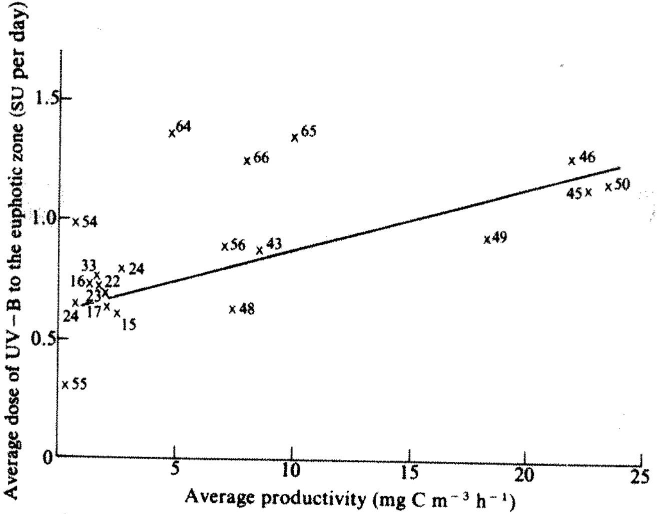

Fig. 1 Typical exposures of marine organisms in the euphotic zone. The average UV – B exposure to the euphotic zone on a sunny summer day, assuming 10 SU incident at the water surface, as measured by the Robertson sensor[3,4]; exposure is plotted as a function of average productivity of the station. Although UV – B transmission varied from station to station, the corresponding changes in visible light transmission tended to maintain a relatively constant exposure in the euphotic zone. Organisms in the more productive euphotic zones receive a somewhat higher UV – B exposure than at stations of low productivity.

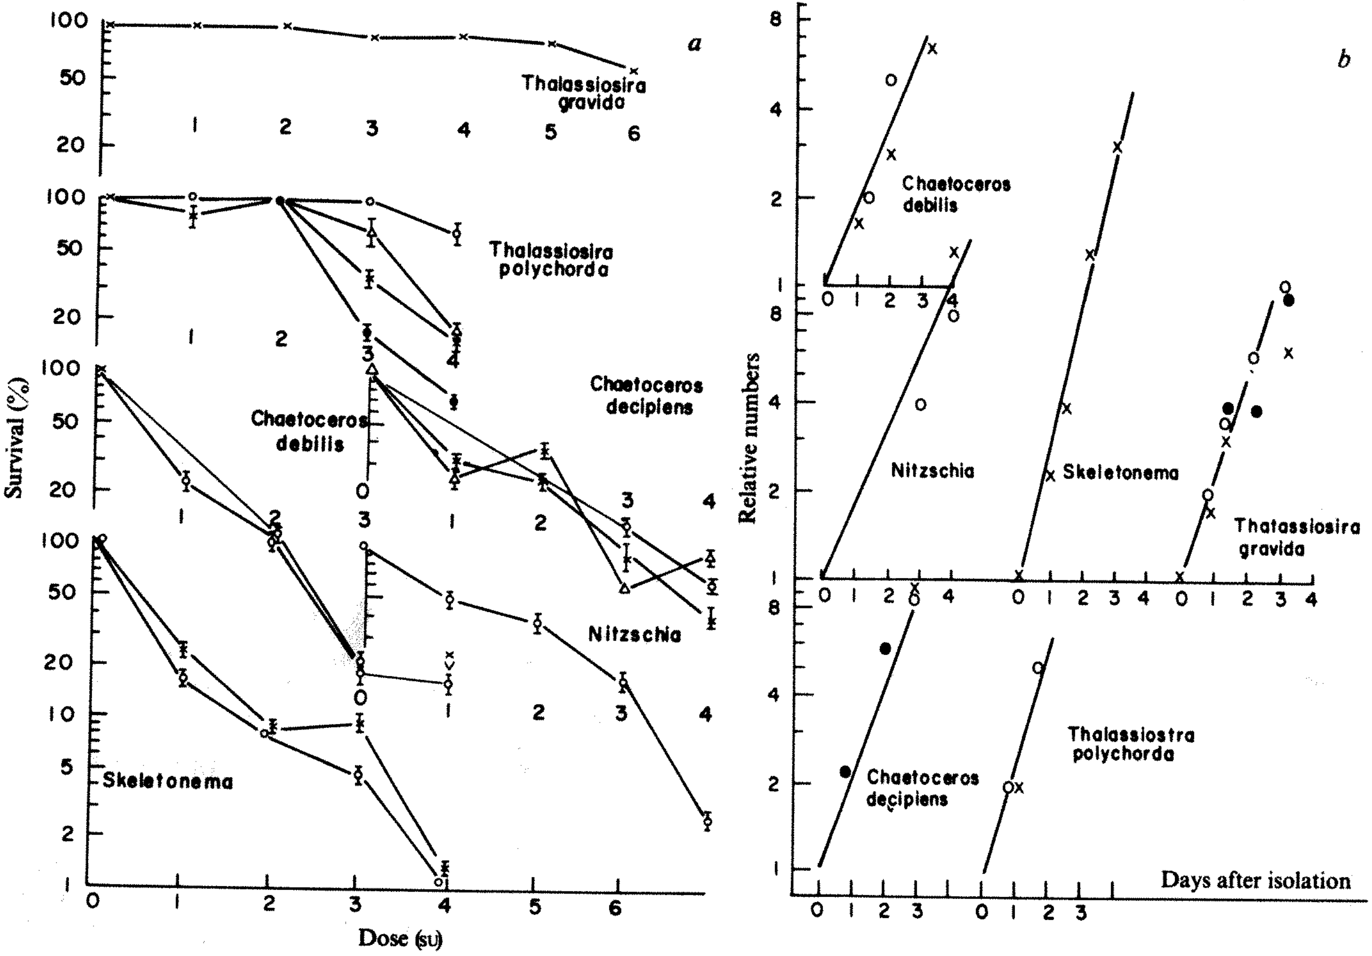

Fig. 2 *a*, The UV – B sensitivity of six marine diatoms. Components of the marine phytoplankton, six common diatoms, were selected as critical organisms for the study of biological response to UV – B. The diatoms were isolated from water samples collected in 1976. *Chaetoceros debilis* and *Chaetoceros decipiens* and *Nitzschia* were derived from collections off the north of Iceland, *Thalassaiosira polchorda*, *T. gravida* and *Skeletonema* were isolated from samples collected near Reykjavik. The diatoms grew well as clones in Erdschribers medium diluted 4 : 1 with seawater; growth was at 7 °C under continuous illumination (1,550 lx) from fluorescent lights. Irradiated and control organisms were isolated into individual depressions containing about 0.25 ml of medium using a micropipette while observing through a low power microscope. The various species of diatoms grow in short connected chains; since the cells of these chains have no protoplasmic connections, but are only linked through inert fibres, we assume that each cell is an independent unit. The various organisms were irradiated with 'simulated' solar UV – B, generated by Westinghouse type FS 20 lamps, and filtered with a Pyrex glass filter of nominal thickness 1/8th inch (ref. 2), monitored using the Robertson sensor; the irradiance from our simulator was 2 SU h^{-1} which approximates the highest irradiance measure in Iceland (1.67 SU h^{-1}). The test organisms were irradiated suspended in medium contained in a small cooled amber plastic dish 2 mm deep, a separate vessel was removed for each dosage and the organisms isolated after the desired exposure times. Two types of controls were run, the 'dark control' was held in a refrigerated incubator at 10 °C in the dark for the time of the longest irradiation (2 h) while a second control, the 'light control', was covered with thick plate glass, thus being exposed to identical conditions except for the UV – B component which was removed by the glass. In all cases the light and dark controls were quite similar in response. The fate of all isolates was followed until the isolated individuals had either died or shown a capacity for sustained growth. A minimum of four post-irradiation divisions was considered to be required to indicate survival. Single cell survival, accounting for control mortality and for multiple organisms in each depression, was computed along the lines previously described[8]. *b*, The growth of marine diatoms. It is assumed that injured populations recover by the growth (division) of survivors, which was determined by repeated counting of isolated diatoms, both unirradiated control organisms and organisms irradiated to various dose levels.

The effects of solar UV – B can be assessed through four independently measurable factors: (1) the amount of solar UV – B incident at the water surface; (2) its attenuation in reaching the position of the various critical organisms; (3) the UV – B sensitivity of the various species comprising the ecosystem; and (4) the capacity of the irradiated organisms to repair injury and replace components of the population killed by UV – B exposure. The four factors have been observed for Icelandic marine ecosystems and compared with similar observations made in Kentucky.[1,2]

As expected, the UV – B irradiance incident on Reykjavik, Iceland (expressed in a biologically weighted unit, the SU)[3,4] reached a peak near midsummer noon (high solar angles), whereas total irradiance was much less dependent on solar angle.

The attenuation of UV – B and visible light was measured at 33 locations in the oceans off Iceland. The productivity of waters from depths of 0, 10, 20 and 30 m was also determined (as ^{14}C incorporation under standard illumination) at many of the stations.

The average irradiance incident in a given volume of water can be calculated using the Morowitz formula[5]. Using the common approximation that the euphotic zone (where photosynthesis > respiration) lies above the depth (Z_{ez}) receiving 1% of the surface irradiance, then the average UV – B dosage to the euphotic zone (during a sunny summer day) can be computed. Figure 1 shows the average UV – B dosage to the euphotic zone plotted against productivity.

The action of UV – B exposures of 0.5–1.5 SU (Fig. 1) can be established by examining the effect of such exposures on key organisms in the marine ecosystem. Figure 2*a* shows the survival response of the six diatom species irradiated with simulated solar UV – B. While *Thalassiosira* spp. were relatively resistant, the other four diatoms showed substantial killing at a radiation dose of 1 SU.

The maximum tolerable exposure to various agents for organisms multiplying asexually can be estimated[2] by determining the replacement limiting dose (RLD) for a species, which is the daily exposure which would kill a fraction of the population just equalling the daily growth capacity of the survivors.

Figure 3 shows the RLD values of various organisms, together with the exposure which they might typically receive. Computed exposure often equals or exceeds the tolerance of organisms; however, the ability of organisms to survive such an apparent excess exposure can be explained on a case by case basis. *Escherichia coli* shows a RLD less than exposure[1], although it is known to have three separate pathways of DNA repair, all of which reduce its sensitivity to sunlight[6]. It might seem that *E. coli* needs to be able to withstand sunlight; however, *E. coli* is well known to 'die off' in natural waters. Because *E. coli* spends most of its life cycle in the sunlight-protected intestine of host animals, species propagation may require short-term survival in natural waters, living only long enough to transfer from host to host.

Some protozoans and arthropods show apparent tolerance levels below the exposure levels in shallow waters (Fig. 3). *Paramecium aurelia* in particular tends to remain at the surface; however, it also shows a preference for shielded surface locations[7] (such as rocks and plants protruding from the water). Another protozoan, *Coleps*, shows a pronounced avoidance of light by moving deep into the water column[7]. Arthropods, *Cyclops*, *Cypris* and *Daphnia*, have also been investigated. *Daphnia* can reach reproductive maturity 10–15 days after birth and produce broods of about five offspring at 10-day intervals thus showing a growth rate of 1.38 per day. RLD would equal 72% survival or 2 SU per day. *Daphnia*, *Cyclops*, and the sensitive protozoa show avoidance of UV – B exposure, coping by behaviour, while the very radiation resistant *Cypris* (RLD > 20 SU) seems to seek intense illumination[7].

Some algae also seem to fall short of the required minimum tolerance. One filamentous freshwater alga, *Rhizoclonium*, floats on ponds during the summer and would seem to require tolerance greater than the 8 SU observed. The surface mat was heavily pigmented and senescent while new growth extended downwards and was protected by the surface layer. This organism seems to reach the required UV – B resistance in the same way as many higher organisms, through specialised protective organs or tissues. Although we lack quantitative data to explain the sensitivity of marine diatoms, they change buoyancy in response to illumination, rising with visible light and falling after UV – B exposure. It is possible that they and unicellular freshwater algae obtain adequate photosynthetic light with minimal UV – B exposure by rising in early morning and late evening and sinking for UV – B protection at midday when UV exposure is greatest, a movement pattern often observed in algae.

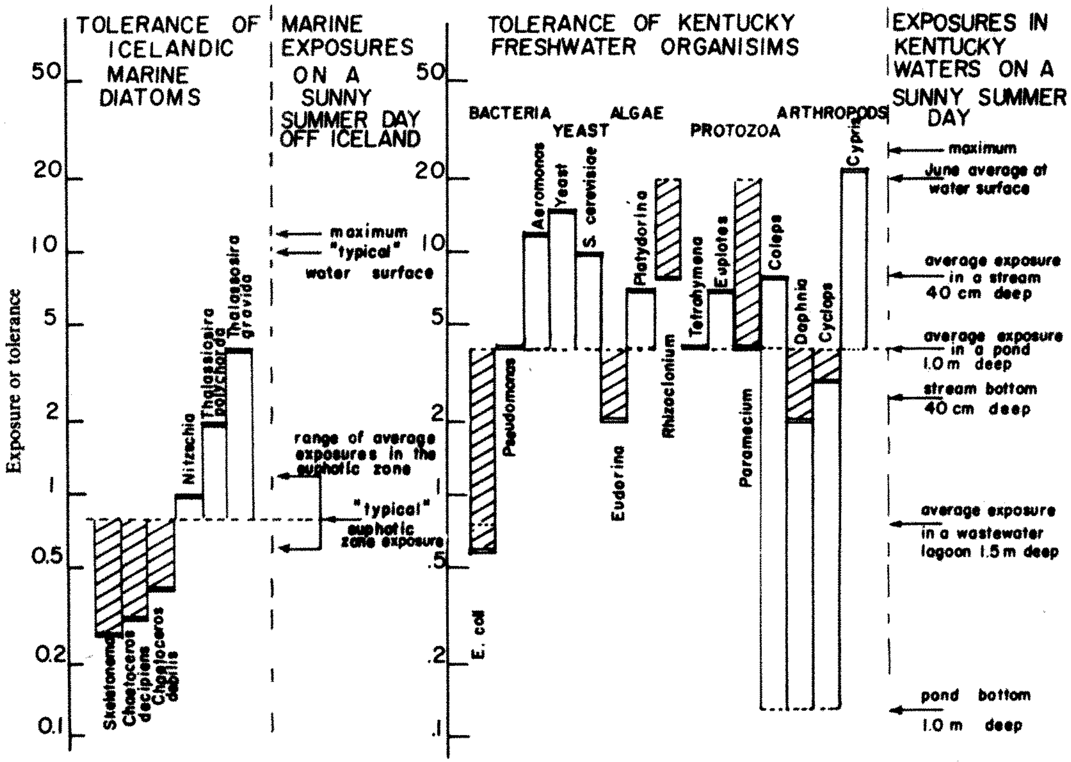

Fig. 3 A comparison of exposure and RLD. Maximum tolerable doses (double bars) are shown for a number of aquatic organisms together with the level of exposure for typical locations where the organisms are found. When exposure is less than tolerance the difference is indicated by solid bars; when exposure exceeds tolerance the difference is indicated by crosshatching. The apparently paradoxical situations where organisms lack sufficient resistance to live in the areas where they are, in fact, found is considered on a case by case basis in the text.

Our findings may be compared with similar calculations made for environmental ionising radiation. The RLD for 'wild-type' *E. coli* is 5–30 krad per day, almost 10^8 times the natural exposure (0.1 rad per yr); for *Tetrahymena pyriformis* the ionising radiation RLD is more than 10^9 times exposure. The ionising radiation resistance of aquatic microorganisms can hardly be an adaptation to a direct stress; resistance to ionising radiation depends on genetic characteristics which could be lost through mutation; resistance to ionising radiation must be a by-product of other requirements, perhaps resistance to solar UV, since the two forms of radiation resistance are highly correlated.

The finding that tolerance and exposure to solar UV are approximately equal strongly implicates solar UV as a significant ecological factor, suggesting that there may be no large reserve of resistance which could cope with altered solar UV exposure without requiring modification of physiology or behaviour. Doubtless most organisms would adapt if the solar UV were to increase. Organisms can increase pigmentation, repair capacity, or avoid solar UV; however, both physiological and behavioural adaptation to solar UV reduces the resources available for other purposes.

We thank our colleagues at the Marine Research Institute, Reykjavik, and in the Department of Radiation Medicine, Lexington, for their assistance. The freshwater research noted here was supported in part by the Office of Water Research and Technology, US Department of Interior under the provisions of Public Law 88-379.

LH-RH in the mesencephalic central grey can potentiate lordosis reflex of female rats

Yasuo Sakuma & Donald W. Pfaff
The Rockefeller University, New York, New York 10021

The lordosis reflex, which characterises female reproductive behaviour in rodents, can be potentiated in oestrogen-primed ovariectomised female rats by electrical stimulation of the ventromedial nucleus of the hypothalamus (VMN)[1]. Subsequent demonstration of an immediate and large facilitation of the lordosis reflex from the mesencephalic central grey (CG)[2] prompted us to speculate that the VMN may exert an oestrogen-dependent tonic bias on the mesencephalic circuitry for lordosis via its heavy descending projections[3]. Moreover, we considered that luteinising hormone-releasing hormone (LH-RH) could be involved in this system. LH-RH can potentiate lordosis when given systemically to oestrogen-primed ovariectomised rats[4,5], and neurotropic effects of this peptide have been shown by microiontophoresis[6,7]. Also, some axons in the CG have been stained with antiserum to LH-RH[8]. The present study examined a possible role of LH-RH in the CG in the regulation of the lordosis reflex of oestrogen-primed ovariectomised female rats. Infusion of exogenous LH-RH in the CG had an immediate facilitative effect on the lordosis reflex, whereas passive immunisation against endogenous LH-RH by anti-LH-RH γ-globulin diminished the reflex.

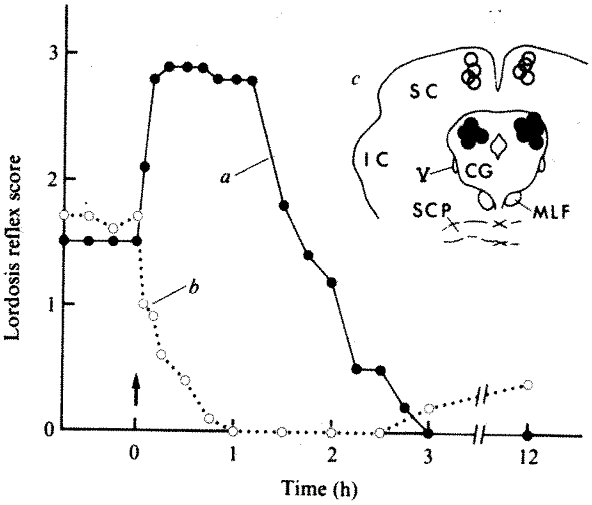

Fig. 1 Successful modification of lordosis reflex performance by LH-RH (*a*, ●) and anti-LHRHG (*b*, ○) in rat no. 6. Infusions were made at 0 h (arrow). *c*, Effective sites of infusions in five rats (●) were in the central grey (CG). Infusions in the superior colliculus (SC, ○) in four rats were ineffective. The diagram was taken from a frontal section of the mesencephalon 6.0 mm posterior to the bregma. Abbreviations: IC, inferior colliculus; MLF, medial longitudinal fascicle; SCP, superior cerebellar peduncle; V, mesencephalic nucleus of the trigeminal nerve.

Intracerebral infusion was accomplished in ovariectomised Sprague–Dawley female rats chronically implanted with stainless steel 22-gauge guide cannulae bilaterally in the CG. The animals received a subcutaneous injection of 5 μg of oestradiol benzoate in sesame oil. They were given a screening test 96 h later, and those which exhibited moderate lordosis in response to manual cutaneous stimulation of the flanks followed by rump-tail base-perineum region[9] were selected. The infusion was made with internal cannulae: 28-gauge stainless steel tubes fitted into the guide cannulae and protruding 0.5 mm from the tip of the latter. LH-RH (Ayerst) was dissolved in saline in a concentration of 100 μg ml^{-1}. Lyophilised sheep anti-LH-RH γ-globulin (anti-LHRHG) and normal γ-globulin (NSG) were dissolved in saline to reconstruct the original concentration in the serum. Each solution was prepared immediately before use, and was infused over a period of 60 s, in a volume of 0.5 μl through each cannula. Two sets of inner cannulae and microsyringes were used for consecutive delivery of the fluid into the bilateral cannulae. Placement of the internal cannulae and the infusion were carried out with the animal in a restrainer but not anaesthetised. The lordosis performance of an animal at a given time was assessed by applying manual cutaneous stimuli five times, at brief intervals. Lordosis reflex strength with each stimulus application was rated using a scale from 0 (no vertebral dorsiflexion) to 3 (strongest possible response), and the average of five ratings was calculated. This average, which we termed the lordosis reflex score, provided virtually identical results when collected independently by two investigators. It has been confirmed that animals with a high reflex score consistently show high receptivity with male rats[1,2]. The lordosis score was usually determined at intervals of 5–30 min during the experiment. Following the completion of observations, tip positions of the internal cannulae were determined in frozen serial sections (100 μm) stained with luxol fast blue and cresyl violet.

Injection of LH-RH into the dorsal part of the CG produced a prompt facilitation of lordosis which was comparable to the effect of electrical stimulation[2]. For example, significant effects could be repeatedly produced with similar time courses in five animals. Facilitation caused by these infusions occurred within 5 min of the end of each application and lasted for about 2 h in each case. Figure 1*a* shows an experiment depicting the time course of the facilitation. This facilitation was followed by prolonged suppression of the reflex in three of the five rats.

0028-0836/80/060566—02$01.00

Increased grooming and licking behaviour often accompanied the facilitation of lordosis, and mere brief contact on the fur of the flanks was sufficient to trigger lordosis in these animals. An equivalent volume of physiological saline had no significant effect when infused into the CG, and infusion of LH-RH into the cerebral cortex also failed to produce any effect.

Passive immunisation with anti-LHRHG resulted in a complete loss of the lordosis reflex when infused into the CG of the same animals. The reflex disappeared within 90 min after the infusion. The suppression of the lordosis reflex persisted for as long as 12 h (Fig. 1*b*). The lack of aggressive behaviour (often elicited in non-receptive female rodents by somatosensory stimuli[10]) was noted when these animals were made unresponsive by anti-LHRHG. NSG injection in the CG had no apparent effect on the performance of lordosis.

Effective sites for the infusions of LH-RH and anti-LHRHG were located in the dorsal half of the CG. Neither LH-RH nor anti-LHRHG had an appreciable effect on the lordosis reflex when infused in the superior colliculus (Fig. 1*c*).

LH-RH bioactivity has been reported to be present in the mesencephalon of the dog and rabbit[11]. By immunohistochemical techniques, some axons in the CG[8] of the guinea pig stain with antiserum to LH-RH. These extra-hypothalamic LH-RH axons have now been implicated in the control of reproductive behaviour. Although a neurotropic effect of LH-RH has not been shown for CG neurones, neurones in the medial basal hypothalamus are either excited or inhibited by microiontophoresis of LH-RH[6,7]. Because electrical stimulation of the CG effectively facilitates the lordosis reflex in oestrogen-primed ovariectomised female rats[2], it is possible that endogenous LH-RH has excitatory effects on the CG neurones involved in the control of lordosis. The origin of mesencephalic LH-RH axons has not been identified, but a contribution of cells in or near VMN cannot be ruled out. LH-RH activity has been detected in the lateral part of the VMN[12]. If this is the case, the requirement for oestrogen in the successful electrical facilitation of lordosis from VMN[1] may be explained at least in part by a requirement for hypothalamic LH-RH[13], which can be mobilised by electrical stimulation. In this context, it may be significant that both LH-RH infusion and VMN stimulation[1] caused long-lasting facilitation of lordosis after each manipulation.

Earlier attempts using infusions of LH-RH[14] or anti-LHRHG[15] to the brain suggested modulatory effects of these substances on the performance of lordosis. With combined observations on the effects of LH-RH and anti-LHRHG, we have now demonstrated that a hypothalamic hormone is necessary for a given behaviour. Blocking the action of decapeptide LH-RH could block lordosis behaviour. In turn, an exact site in the brain where LH-RH is required, the midbrain central grey, was revealed by the location of the microinfusion cannula tips. The identification of a specific neurochemical (LH-RH) needed for reproductive behaviour and a particular site of action may allow specific interference with mating behaviour, with other behavioural responses left undisturbed.

This work was supported by NIH grant HD-05751 and an institutional grant from the Rockefeller Foundation for the study of reproductive biology. We thank Dr A. Arimura for the gift of sheep anti-LHRHG, and Nicholas Brodyn and Birgit Rogers for technical assistance. Y.S. is on leave from the University of Gunma Medical School, Maebashi, Japan.

Paternal investment of urates in cockroaches

Donald E. Mullins & Clifford B. Keil

Department of Entomology, Virginia Polytechnic
Institute & State University, Blacksburg, Virginia 24061

During copulation, the male German cockroach [*Blattella germanica* (L.)] deposits a spermatophore in the female's genital pouch and voids stored urates from his accessory glands (uricose glands) on to the spermatophore[1]. About 24 h after mating, the female expels the empty spermatophore with adhering urates. Although uricose glands have been reported in the Blattaria[2,3], and are proposed to act in excretion[4,5], their role in reproduction is unclear. Roth[2] has suggested that urates may serve to protect the spermatophore from premature consumption by the female or other insects. However, we have noted the disappearance of spermatophores/urates from cages containing mated pairs of cockroaches and have investigated the possibility that these materials have nutritional value. We observed that spermatophores and urates disappeared between 7 and 18 d after females were mated while on a dog food diet; spermatophores were consumed within 4 d by females starved for 3 d after eclosion. Furthermore, we now report that labelled uric acid assimilated by males before, and voided at, mating can be recovered in mated females and their ootheca.

Accessory glands containing high levels of labelled urates were obtained by injecting males with [8-^{14}C]hypoxanthine (Table 1). One of each labelled pair of males mated successfully and after 38 d all females and their oothecae were radioactive. Table 1 shows that females on a low protein (5%) diet

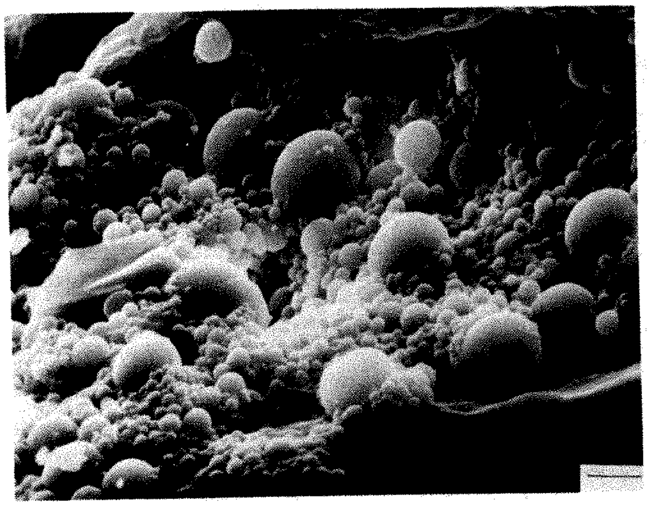

Fig. 1 A scanning electron micrograph (SEM) of the edge of an emptied spermatophore with adhering urate spherules which are secreted/deposited by males at the time of mating. These urates may be consumed (along with the spermatophore) and used by the female and/or be subsequently incorporated into the ootheca as a nitrogen resource. Before viewing, the specimen was coated with a 60:40 mixture of gold/palladium. It was examined with an Advanced Metals Research SEM (Model 900-52) equipped with EDAX (energy dispersive X-ray analysis, Model 707A). Scale bar, 5 μm.

0028–0836/80/060567—03$01.00

Table 1 Fate of labelled ^{14}C-hypoxanthine injected into young adult male *B. germanica* which were subsequently presented to young adult females

Diet	Whole insect/oothecal activity in (d.p.m.)			
	Females	Oothecae	Mated males*	Unmated males
5% Protein	2,073 ± 961 *a*†	9,417 ± 2,725 *b*	51,681 ± 9,181 *c*	103,948 ± 3,688 *d*
25% Protein	2,486 ± 704 *e*	800 ± 275 *f*	70,635 ± 4,256 *g*	107,746 ± 3,905 *h*

Adult males (1–3 days old reared on dog food) were injected with 1 μl[8-^{14}C]hypoxanthine, resulting in a measured 181,418 ± 6,697 d.p.m. per insect. They were maintained on 25% casein protein diet for 10 days, followed by presentation of two males (see below) to one young virgin female (reared on dog food) in a plastic Petri dish supplied either with a 5% protein or a 25% casein protein diet and water. In addition, unmated males (maintained on 25% casein protein) were frozen 10 and 48 days after isotope injection. Stock cultures, rearing conditions and diet formulations used are described elsewhere[12,16,17]. Before extraction, insects and oothecae were rinsed several times in 0.6% Li_2CO_3 at 30 °C to remove any labelled material adhering to their exteriors. Whole insect assay included homogenising whole bodies in 0.6% Li_2CO_3 at 80 °C for 10 min, centrifugation at 1,000*g* for 10 min and counting in PCS (Amersham/Searle)/xylene scintillation cocktail. Oothecae were extracted in 0.1 M Tris-HCl, buffer *p*H 7.4, at 30 °C, centrifuged and counted as above. A portion of these extracts was frozen for subsequent analysis (Table 2). Data represent the mean ±s.e.m. ($n = 8$ females per diet). Ten days after injection virgin males contained 124,279 ± 8,443 d.p.m. per insect and after 48 days they contained 107,908 ± 2,203 d.p.m. per insect ($n = 4$). Accessory glands contained 57,989 ± 14,066 and 36,365 ± 1,644 d.p.m. per mg ^{14}C-urate in tissue obtained 10 and 48 days after injection, respectively ($n = 4$). Purification of these extracts indicated that virtually all the activity in this tissue could be attributed to labelled urate. One discarded spermatophore/urate obtained from a mated pair contained a total activity of 54,976 d.p.m. in the extracted urate fraction. ^{14}C-hypoxanthine was used instead of xanthine or uric acid because of its greater solubility in aqueous solutions; this facilitated the process of injecting relatively constant amounts in each insect. The subsequent conversion of hypoxanthine to uric acid stored as urates in the males proved to be quite suitable for our purposes.

* Virgin females were provided with two males to allow an optimal opportunity for mating to occur. In these conditions only one male will normally mate successfully[18], presumably releasing its urate stores. We have arbitrarily segregated the males on the basis of whole body activity, hence 'mated males' were compared with 'unmated males'. These differences are highly significant (see below).

† Statistical analysis using the Student's *t*-test indicated the following: $a = e, P < 0.7321$; $b \neq f, P < 0.0152$; $c \neq g, P < 0.082$; $d = h, P < 0.4868$; $c \neq d, P < 0.0001$; $g \neq h, P < 0.0001$.

incorporated more activity into their oothecae than did those maintained on 25% casein protein diet. The amount of label consumed and transferred to the ootheca varied considerably. Presumably, this variation reflected the amount of label excreted by males, the feeding activity and nutritional status of females. Obviously, these radioactivity transfer estimates could have been influenced by metabolism of urates to $^{14}CO_2$, which was not measured.

The disappearance of deposited spermatophores/urates suggests that the major route of urate entry into females is the alimentary canal. This does not preclude the possibility that a small fraction may enter by the genital tract[6]. Radioactivity within oothecae was mainly in the soluble fraction, with very little in the precipitated protein or oothecal cases (Table 2). Analysis of the soluble fractions indicated that the major radioactive component was uric acid. Urate content was examined in oothecae at different stages of embryonic development and newly hatched nymphs. Newly formed oothecae contained 2.8 ± 0.1 μmol uric acid and newly hatched 1st instar nymphs plus their empty oothecal cases contained 1.2 ± 0.1 μmol. Correlation analysis showed a significant decline in uric acid levels during embryogenesis ($y = -0.056x + 2.72$; Pearson's $\rho = -0.789$; $P < 0.0001$). This decline strongly suggests that uric acid is metabolised during embryonic development.

Large nutritional demands are made on the metabolism of the female German cockroach during oothecal production. Kunkel[7] has shown that the female incorporates almost 90% of her food reserves accumulated during the preovipositional period into a single ootheca. A portion of these reserves are nitrogen-containing materials which are transferred to the oocyte in the form of vitellogenin, appearing in the female blood 3 or 4 days after adult ecdysis and disappearing soon after terminal oocytes have been released into the ootheca[8]. It now seems that females are also incorporating uric acid into developing oocytes. Because uric acid levels decrease significantly as the embryo develops, it is likely that this incorporated uric acid is metabolised during embryogenesis.

Another event occurring during oogenesis is trans-ovarian transmission of symbiotic bacteroids (mycetocyte bacteroids) from females to the oocytes[9]. Although the precise role of cockroach mycetocyte bacteroids is not clearly understood, they have been implicated in amino acid, urate and vitamin metabolism[9–12]. It is possible that these bacteroids might play an important part in the metabolism of oothecal uric acid.

There have been several reports that female Orthoptera consume a spermatophore which has been ejected after mating, and it may not be uncommon for a male to transfer materials of nutritional value in the accessory gland secretions[6,13,14].

Gordon[15] has characterised cockroaches as being versatile omnivores capable of surviving on foods of low quality and limited quantity. Also, those nutrients most likely to be stored are those which may be of limited supply in the environment. Storage of urates (which are generally viewed to be end products of nitrogen metabolism and discarded by most higher uricotelic organisms) as a nitrogen resource by organisms adapted to utilise them in conditions of dietary stress has obvious advantages[12].

We suggest that male *B. germanica* urate secretions (Fig. 1) may represent paternal investment of a nitrogen resource from which the female and her progeny might benefit. The evidence presented that urates secreted during mating are incorporated into ootheca at various levels related to the dietary nitrogen status of the parents, and the discovery that uric acid is present in newly formed oothecae emphasise the importance of this material to this group of insects. However, little is known about catabolism of uric acid. Studies using ^{14}C-labelled purine intermediates reflect only pathways involving the carbon atoms and do not necessarily reflect the path of nitrogen contained in

Table 2 Distribution of radioactivity in whole oothecae obtained from female *B. germanica* which had been paired with labelled males for 38 days

Diet	Soluble fraction		Precipitated fraction	Oothecal cases	Total
	d.p.m.	Uric acid*	d.p.m.	d.p.m.	d.p.m.
5% Protein	9,470 ± 2,751	58%	88 ± 18	163 ± 60	9,721 ± 2,790
25% Protein	727 ± 314	88%	15 ± 3	22 ± 8	760 ± 323

Frozen oothecal extracts obtained from the experiment described in Table 1 were heated, centrifuged and the supernatant (soluble fraction) counted in PCS/xylene solution. The precipitated pellet was resuspended and washed several times before suspension in the counting solution. The oothecal cases were extracted several times in heated buffer and ground to a very fine powder before placement in counting solution. The per cent uric acid content was obtained from pooled samples of the soluble fractions (5% protein and 25% casein protein) after purification by TLC (1-mm cellulose plates developed in *n*-butanol/methanol/H_2O/60 : 20 : 20 : 1) and scintillation counting.

* Uric acid present in the urate spherules excreted by the males is partially potassium urate, hence we refer to it as urate. However, because nothing is known about its form in the ootheca, we refer to it as uric acid.

urates. Therefore, investigations designed to elucidate these relationships further might prove useful.

Chronic blockade of dopamine receptors by antischizophrenic drugs enhances GABA binding in substantia nigra

Karen Gale

Department of Pharmacology, Georgetown University Schools of Medicine and Dentistry, 3900 Reservoir Road, Washington, DC 20007

Antischizophrenic drugs exert their primary effects through blockade of dopamine (DA) receptors in the central nervous system (CNS)[1-3]. However, because of intricate interconnections between neural pathways, alteration of DA function in the CNS can lead to changes in the function of other neurotransmitters. In the basal ganglia, the turnover and utilisation of several neurotransmitters, including γ-aminobutyric acid (GABA)[4-6], are indirectly influenced by nigrostriatal DA activity[7-10]. However, although attention has been focused on changes in DA receptors[11,12], relatively little is known about changes in receptors for other transmitters after chronic antischizophrenic drug treatment. It is likely that changes occurring one or more synapses removed from the drugs' primary site of action may account for some of the time-dependent changes in the therapeutic and adverse clinical effects of antischizophrenic drugs[13,14]. In the substantia nigra (SN), a reduction in GABAergic inhibitory tone and a possible increase in the release of excitatory transmitter such as substance P are effects which seem to accompany the acute blockade of striatal DA receptors[15]. Recent studies have shown that a chronic decrease in GABA function in the SN, through the destruction of striatonigral pathways[16,17], produces an increase in the number of GABA binding sites in the SN[14,15]. Therefore, if a relative deficit of GABA transmission in the SN were to be maintained by chronic antischizophrenic drug treatment, an increase in nigral GABA binding might occur. To investigate this possibility, two classical prototype antischizophrenic drugs (chlorpromazine and haloperidol) were examined for their effects on specific GABA binding in the SN and striatum of rats. These effects were compared with those of clozapine, an antischizophrenic drug with an atypical biochemical and clinical profile[4,18-23]. The data obtained, and reported here, support the hypothesis that chronic blockade of dopamine receptors by classical antischizophrenic drugs enhances GABA binding in the SN. This effect may be related to the extrapyramidal side effects associated with classical antischizophrenic drug treatment[13].

Male Sprague–Dawley rats, weighing 200 g at the start of the experiments, were treated for 8 weeks with daily subcutaneous (s.c.) injections of haloperidol (0.7 mg per kg), chlorpromazine (20 mg per kg) or clozapine (20 mg per kg). At the end of the 8-week period, 5 days elapsed without drug administration before the rats were killed for measurement of ^{3}H-GABA binding. Binding measurements were made in a crude synaptosomal–mitochondrial membrane preparation which had been frozen and thawed, treated with Triton X-100 (0.01% for 60 min at 37 °C) and washed extensively[17,24,25].

Table 1 shows the amount of specific ^{3}H-GABA binding in the SN of drug-treated groups. When compared with values from control rats which received daily injections of vehicle, the values obtained from rats receiving either chronic chlorpromazine or haloperidol treatment were significantly elevated. In the same rats in which this increase in specific ^{3}H-GABA binding was found in the SN, no change in specific ^{3}H-GABA binding was obtained in the striatum (Table 1). In contrast, chronic clozapine treatment did not cause a significant change in the specific binding of ^{3}H-GABA in the SN. No changes in specific GABA binding were observed in the SN after acute drug administration (1 h before killing), indicating the importance of chronic treatment for producing an increase in nigral GABA binding. The SNs from several chronically treated rats were pooled for binding studies using a range of GABA concentrations (10–90 nM). Scatchard analysis revealed that the increased GABA binding in the SN of chlorpromazine- and haloperidol-treated rats was due to an increase in B_{max} and not to a change in affinity (K_D) of the binding sites for GABA (see Table 1 legend).

Thus, the classical antischizophrenic drugs, chlorpromazine and haloperidol, although not acutely changing nigral binding sites for GABA, on repeated administration can cause an increase in the apparent number of these binding sites. As GABA binding in the striatum did not change, the increase observed in the SN does not represent a general response of brain GABA receptors to these drugs but probably reflects the juxtaposition of specific neural pathways. As in the case of lesions of striatonigral GABAergic projections[16,17], the increase in nigral GABA binding after chronic drug treatment may represent a compensation for a decrease in the synaptic activity of GABA. This possibility is consistent with the evidence that chronic treatment with haloperidol or chlorpromazine reduces the turnover rate of GABA in the SN[4].

The lack of effect of chronic clozapine treatment on GABA binding in the SN is probably related to the unique pharmacology of this compound. Clozapine does not cause catalepsy in animals and is devoid of Parkinson-like extrapyramidal side effects in man[18,19]. There is evidence that the DA receptors affected by clozapine may be functionally distinct from those affected by haloperidol and chlorpromazine[20-22]. In addition, clozapine's blockade of muscarinic cholinergic receptors[23] may interfere with this drug's ability to activate the striatonigral pathways required for the suppression of GABAergic transmission in the SN. Thus, acute clozapine treatment, unlike haloperidol or chlorpromazine, causes an increase in the turnover rate of GABA in the SN[4].

To evaluate the possible significance of an alteration in nigral GABA receptors, the functional role of these receptors must be considered. Activation of GABA receptors in the SN can prevent the stimulation of tyrosine hydroxylase and DA synthesis which occurs in the striatum after an acute injection of haloperidol[26]. Thus, an increase in SN GABA receptors after chronic haloperidol and chlorpromazine may contribute to the gradual decline in the ability of these drugs to enhance DA turnover[22,27-30]. In addition, non-DA pathways originating in the SN zona reticulata are contacted by GABA terminals[31] and probably contain GABA receptors[32,33]. These latter pathways may mediate the DA-independent behavioural responses (contralateral rotation or stereotypies) evoked by the direct unilateral or bilateral activation of nigral GABA receptors in the rat[34-38]. Stimulation of nigral GABA receptors can also

Table 1 ^{3}H-GABA specific binding (fmol per mg protein) in SN and neostriatum after chronic treatment with antischizophrenic drugs

Chronic treatment (mg per kg, s.c.) (8 weeks)	SN†	Striatum†
Control	382±15	322±13
Haloperidol (0.7)	501±32* (131)	331±18 (103)
Chlorpromazine (20)	521±30* (136)	348±13 (108)
Clozapine (20)	360±19	338±15 (105)

Values represent the means of 15 rats (3 separate experiments, 5 rats each) ±s.e.m. Rats were killed by decapitation and the SN and striatum dissected out as previously described[15] and placed on dry ice. For each SN determination, both SNs (8 mg wet weight tissue) from one rat were combined; this yielded enough protein (300–400 μg in the final membrane preparation) to run triplicate samples for binding. Tissue was prepared according to the method of Enna and Snyder[24]; as described by Toffano *et al.*[25], this preparation results in the removal of a membrane-bound protein inhibitor of high-affinity GABA binding. Binding was measured at 0 °C in a Na^+-free medium in the presence of 30 nM ^{3}H-GABA; nonspecific binding was measured in the presence of 10^{-3} M nonradioactive GABA[24]. The SN from groups of three or four rats were pooled to obtain values for Scatchard plots of high-affinity binding (10–90 nM ^{3}H-GABA)[17]. In these conditions, linear regression analysis of the data indicated that the K_D values of haloperidol (42±5 nM) and chlorpromazine (40±5 nM) rats were not significantly different from those of controls (36±4 nM). Values of B_{max} (pmol per mg protein) were: control, 1.19±0.06; haloperidol, 1.61±0.10*; chlorpromazine, 1.58±0.12*.

* Values significantly different from controls, $P < 0.05$.

† Numbers in parentheses refer to % of control.

reverse the catalepsy induced by haloperidol[36]. These data suggest that GABA receptors in the SN, functioning downstream from the influence of DA neurones, may participate in the relay of neural output from the basal ganglia.

From this perspective, it is tempting to speculate that a modification of nigral GABA receptors, produced by classical antischizophrenic drugs, may be responsible for some of the behavioural consequences of their long-term administration. Thus, the development of tolerance to catalepsy[27] and the gradual increase in the ability of DA agonists to induce stereotyped behaviour[39,40] in animals, as well as the disappearance of parkinsonian symptoms and the appearance of dyskinesias in humans[13], are examples of processes which occur in response to chronic treatment with antischizophrenic drugs, and which may be brought about by 'supersensitive' receptors, not only for DA, but also for GABA.

Effects of 4-aminopyridine on normal and demyelinated mammalian nerve fibres

R. M. Sherratt, H. Bostock & T. A. Sears

Sobell Department of Neurophysiology, Institute of Neurology,
The National Hospital, Queen Square, London WC1N 3BG, UK

We have previously demonstrated that a drug which prolongs action potentials can, like a reduction in temperature, overcome conduction failure in demyelinated nerve fibres[1]. Although the particular substance then used, a scorpion venom, was not a suitable therapeutic agent, we suggested that other drugs, with similar but milder effects on the action potential, might be effective in the symptomatic treatment of multiple sclerosis[2]. We now report some encouraging results obtained with 4-aminopyridine (4AP), a substance which blocks the voltage-dependent potassium currents in squid giant axons[3]. The use of a potassium-blocking agent to prolong action potentials may seem surprising because we previously found tetraethylammonium chloride (TEA), another potassium blocker, ineffective on normal rat myelinated fibres[1], and two recent voltage-clamp studies have confirmed that mammalian nodes have few, if any, potassium channels[4,5]. On the other hand, 4AP strongly potentiates transmitter release from the unmyelinated terminals of rat motor nerves[6], and the possibility arose that demyelinated axon membrane, which can conduct impulses continuously like an unmyelinated fibre[7], might further resemble its unmyelinated terminals by responding to 4AP. In testing this hypothesis, we have found that both TEA and 4AP prolong action potentials of demyelinated and unmyelinated fibres, and both facilitate conduction in fibres blocked by demyelination. 4AP is effective at lower concentrations, and is the more promising for clinical use, as it has already been used with beneficial effects in the treatment of Eaton-Lambert syndrome[8] and myasthenia gravis[9].

The contrasting effects of 4AP on normal A and C fibres are most readily seen by comparing the effects on the A and C elevations of the same dorsal root compound action potential. To obtain the records in Fig. 1, a rat was anaesthetised with urethane, and after laminectomy a lumbar dorsal root was raised on stimulating and recording electrode pairs in a paraffin pool maintained at 37 °C. The compound action potentials evoked at low and high stimulus strengths were recorded monophasically from near the cut central end. At low stimulus strength, the 4AP had no effects on the main A-fibre spike (although at high gain the after potential became more negative); the C-fibre

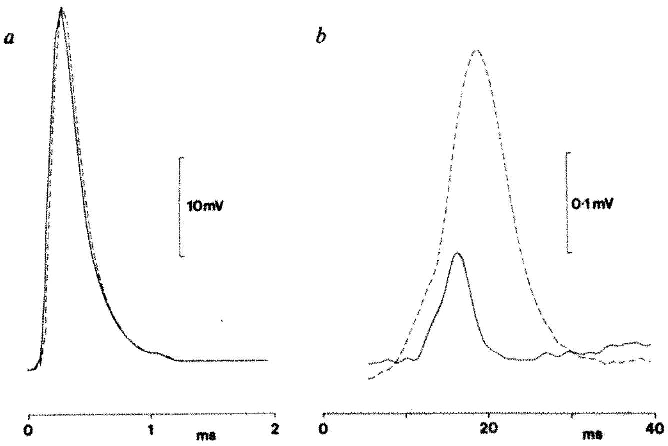

Fig. 1 Effect of 4AP on compound action potential in rat dorsal root, showing myelinated (*a*) and unmyelinated (*b*) fibre components separately. Each trace is the mean of eight, obtained with a digital signal averager. Solid lines, control; dashed lines, following application of 4 mM 4AP.

component, however, obtained by subtracting the low stimulus response from the high stimulus response, was increased in area severalfold. Of 17 dorsal roots treated with 5 mM 4AP, the increase in peak height of the C component ranged from 4% to 550%, with a median of 127%.

To determine whether the change in the C-fibre compound action potential was due simply to a prolongation or to some other change in the individual C-fibre action potentials, and to determine the effect on demyelinated axons, it was necessary to record from single fibres. Figure 2 shows typical examples of the effects of 4AP on the action potentials of single myelinated (*a*), unmyelinated (*b*) and demyelinated (*c*) nerve fibres, also recorded from rat spinal roots. In *b*, the single fibre was stimulated and recorded as in Fig. 1, and judged to be unmyelinated from its conduction velocity of 0.43 m s^{-1} at 30 °C. It was functionally isolated from the myelinated fibres in a dorsal root filament by latency, and from the other unmyelinated fibres by its threshold. In *a* and *c* the action potentials of single fibres in sacral ventral roots were isolated by adjusting the position and intensity of a stimulus to the tail. In *c* the demyelination was caused by intrathecal injection of diphtheria toxin 12 d previously[7]. In each case digital averaging was used to improve the signal-to-noise ratio, and in *a* and *c* the averager sweep was triggered by the spike as described previously[7]. As with the compound dorsal root A spike, the single ventral root myelinated fibre action potential was unchanged by 5 mM 4AP. The single unmyelinated fibre action potential, on the other hand, was prolonged and increased slightly in amplitude. The demyelinated fibre had an action potential of irregular shape, as is usual, and this was also prolonged.

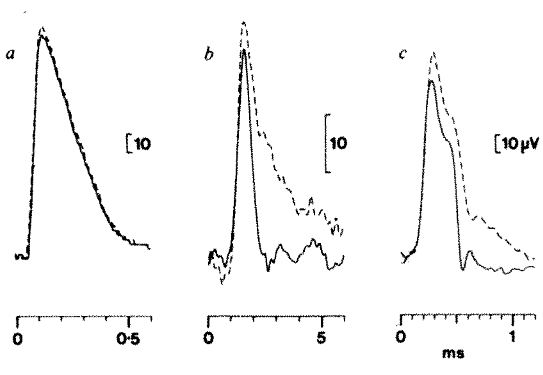

Fig. 2 Effects of 4AP on single fibre action potentials. *a*, Myelinated (37 °C); *b*, unmyelinated (30 °C); *c*, partially demyelinated fibre (37 °C). Each trace is the mean of 64. Solid lines, controls; dashed lines, following application of 5 mM 4AP.

The mechanism of action potential prolongation is best revealed by records of membrane currents, which can be calculated by subtracting adjacent records of longitudinal current, made between closely spaced pairs of electrodes[10]. Membrane current starts in the outward direction as the approaching action potential depolarises the membrane, and in myelinated axons only becomes inward at the nodes, when they are excited. Figure 3 shows the effects of 4AP on the membrane currents at two consecutive nodes in a dorsal root fibre exposed to diphtheria toxin 6 d previously. Conduction in this fibre was saltatory, except for one demyelinated internode, over which conduction was continuous, at only 1.1 m s^{-1} (30 °C). The abnormally large and slow currents in this region resembled those described previously for continuously conducting internodes[11]. The node in Fig. 3*a* was unaffected by the toxin, judging from the small amount of outward current required to depolarise it to threshold, and the 4AP had little effect. The currents in Fig. 3*b* were recorded from the next 'node' 1 mm away, which was also the start of continuous conduction. As at succeeding electrode positions in the demyelinated internode, the membrane currents had three conspicuous phases: outward current during passive depolarisation, active inward current and a late outward current phase. This late phase of outward current, occurring at the time an active potassium current would be expected, was abolished by 4AP, although conduction along the internode persisted at 1.1 m s^{-1}.

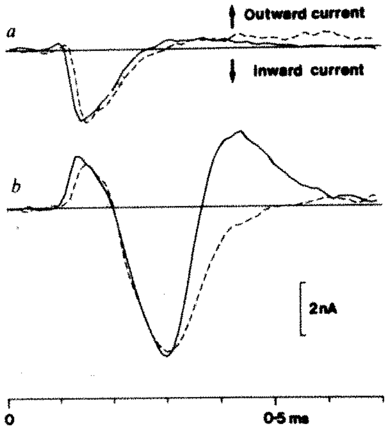

Fig. 3 Effects of 4AP on membrane currents of two consecutive nodes 1 mm apart in single dorsal root fibre exposed to diphtheria toxin. Each trace obtained by subtracting averaged longitudinal currents ($n = 64$) recorded 200 µm apart, so that points below the baseline denote inward current. Solid lines, controls; dashed lines, following application of 5 mM 4AP.

We have observed the abolition of a late phase of outward current in two other continuously conducting internodes treated with 4AP. We have also observed a similar effect at individual nodes showing signs of paranodal demyelination after diphtheria toxin injection. Of 30 nodes examined as in Fig. 3, we have found a prolongation of net inward current only at those eight nodes which took much longer than normal to be excited. These results strongly suggest that the axon membrane exposed by demyelination has different excitability properties from those of normal nodes, with a much higher proportion of potassium channels. This interpretation must remain speculative without voltage-clamp data, but receives some support from a recent voltage-clamp study of single rat nodes: potassium currents, normally weak compared with amphibian nodes, were increased in rats made diabetic with alloxan[4]. Whatever the explanation, the extranodal membrane more closely resembles, in its response to 4AP, the membrane of unmyelinated fibres, than that of normal nodes.

If 4AP prolongs action potential at demyelinated, but not at normal nodes, it might be expected to aid conduction through a diffuse demyelinating lesion, although it could not help transmission from the last normal node to the first affected one. We have tested the effects of 4AP on the blocking temperatures of 16 demyelinated single fibres, using the method previously described for scorpion venom[1]. The blocking temperature was raised (that is, transmission was improved) in 12 and lowered in only two cases, although in four cases the responses did not follow a simple time course. The effects were not as striking as those of scorpion venom[1], which acts by inhibiting sodium inactivation, but in view of the limited prolongation of the action potential that could occur with a blocking agent for potassium channels they were encouraging. One reason for testing 4AP was that it has already been used clinically and can be tolerated in patients at a concentration sufficient to enhance transmitter release from unmyelinated motor nerve terminals[8,9]. There are grounds for hoping that potassium channel blockers such as 4AP will also prove to be of value in the symptomatic treatment of multiple sclerosis and other demyelinating disease, through their specific action at those sites in myelinated fibres that most resemble their unmyelinated terminals.

Abrogation of genetically controlled resistance of mice to *Treponema pallidum* by irradiation

John R. Klein, Andrew A. Monjan, Paul H. Hardy Jr & Gerald A. Cole

Departments of Epidemiology and Microbiology, The Johns Hopkins University Schools of Hygiene and Public Health, and Medicine, and the World Health Organisation Collaborating Center for Reference and Research in Treponematoses, Baltimore, Maryland 21205

Infection with *Treponema pallidum*, the causative agent of human syphilis, gives rise to a complex immune response involving both humoral and cellular components. The exact nature of this response and how it relates to the disease process is a matter of considerable speculation[1,2]. In recent years, studies have been directed towards defining the role of cell-mediated immunity (CMI) in syphilis[2]. These have been conducted mainly *in vitro* because the general unavailability of inbred rabbits, the principal animals for experimental syphilis research, has limited the application of *in vivo* procedures. A prime deterrent to using mice for the study of syphilis has been their failure to exhibit pathology, even in the face of a persistent infection[3,4]. We report here that on intradermal (i.d.) infection, transient primary lesions, characteristic of those seen in naturally acquired human syphilis, can be produced regularly in some strains of mice but not others, indicating a genetic basis for host susceptibility. Strains of mice which normally fail to develop lesions, do so after exposure to ionising radiation. Evidence is presented for a multiple role of the immune response during local infection.

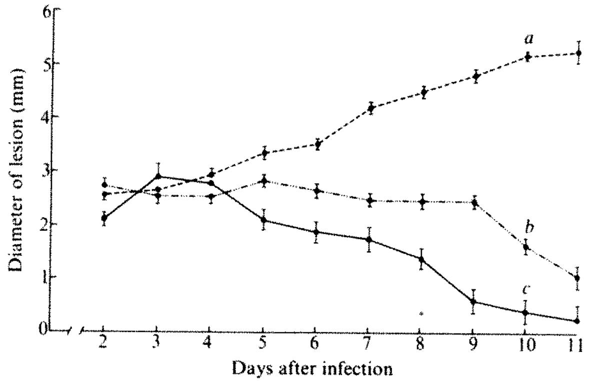

Fig. 1 Progression of lesion size in infected C3H/He mice. Each point represents the mean value ± s.e.m. of 15 normal mice (*c*), 10 irradiated mice reconstituted with non-immune cells as described for Table 2 (*b*), and 15 irradiated mice (*a*). The kinetics of lesion development seen in irradiated BALB/c and Swiss mice were the same as shown for C3H/He mice (*a*). Inoculation procedures consisted of i.d. injection into an area of the backs of anaesthetised mice from which hair had been removed by clipping and the application of a depilatory cream. Each animal received 0.01 ml of a suspension of *T. pallidum*, 6×10^8 per ml, derived from an orchitic rabbit preparation as previously described[12], and an equal volume of the same suspension rendered non-infectious by aerobic storage for 4 d at 4 °C. All mice were maintained at 16–18 °C, temperatures which are known to promote cutaneous pathology in other *T. pallidum*-infected animals[8]. Inocula of $>10^4$ organisms were required to elicit a cutaneous lesion.

Mice infected i.d. and housed at 16–18 °C develop prominent lesions at the site of inoculation within 48 h, appearing as well demarcated, indurated papules which increase in size until day 4 of infection, and then gradually recede (Fig. 1). Depending on mouse strain, 40–60% of lesions become necrotic and form an overlying crust of dry inflammatory exudate from days 4 to 9 of infection. Histologically, these lesions are characteristic of the pathologic changes of primary syphilis. Beginning on day 2 of infection, there is an accumulation of mononuclear cells consisting of macrophages, lymphocytes and, subsequently, plasma cells throughout the epidermis and dermal collagen and fat. About one half of the lesions progress to ulceration or display a marked thinning of the epidermis beneath an accumulation of dense nuclear debris and inflammatory exudate, persisting until

Table 1 Frequency of lesions in *T. pallidum*-infected normal and irradiated mice

Strain	H-2 haplotype	No. mice with lesions/ no. tested (%) Non-irradiated	Irradiated
Swiss	—	3/40 (7.5)	40/40 (100)
C3H/He	k	40/50 (80)	43/43 (100)
DBA/2	d	14/35 (40)	NT
C57BL/6	b	20/54 (37)	NT
BALB/c	d	8/40 (20)	35/35 (100)
AKR	k	2/10 (20)	NT
(C3H/He × BALB/c)F$_1$	kd	10/14 (71)	NT

Lesions were scored at day 4 of infection, the time of maximum frequency in non-irradiated mice. By day 2 of infection, all irradiated mice developed lesions which persisted until death. Using a bacterial counting chamber, the concentration of treponemes in undiluted, wet-mounted preparations of serous material taken from 8-d lesions in irradiated C3H/He mice was $3.15\pm0.22\times10^9$ per ml (mean of 5 mice ± s.e.m.); similar numbers of treponemes were found in material from lesions of irradiated BALB/c and Swiss mice. By χ^2 analysis, lesion frequencies in C3H/He mice differed significantly ($P<0.005$) from all other strains except the (C3H/He × BALB/c) F$_1$ group. Frequencies in BALB/c and AKR mice were the same; differences between BALB/c and DBA/2 mice were not highly significant ($P=0.05$). NT, not tested.

0028-0836/80/060572—03$01.00

days 7 to 10 of infection. Both gross and microscopic characteristics are similar for all strains of mice tested. Sites of control inoculations with non-infectious organisms exhibit only transient, colourless blemishes during the first 24–48 h, and never develop crusted surfaces. Histological changes are minimal, consisting of occasional mild supperative inflammation which resolves within 24–48 h of inoculation.

As shown in Table 1, there is marked variation in the susceptibility of mice to lesion development which is least in outbred animals, a significant point as most published studies of murine syphilis have involved such animals[3,5]. Inbred strains display a spectrum of susceptibility with C3H/He mice developing lesions most consistently. The high lesion frequency seen in (C3H/He × BALB/c)F_1 mice may suggest that the factor(s) responsible for the clinical manifestation of infection are under genetic control, although more detailed studies along these lines will be required to define the exact nature of this relationship. Susceptibility seems not to be influenced by H-2 haplotype, a situation also applying for certain other bacterial infections of mice[6,7]. Consistent with the phenomenon of chancre-immunity that occurs in human syphilis and experimental *T. pallidum* infections of other animals[8], mice which develop primary lesions become completely resistant to i.d. treponemal challenge by day 20 of infection.

The importance of an intact immune system in the outcome of local infection was dramatically illustrated by the use of radiation-induced immunosuppression. Mice were exposed to lethal doses of total body irradiation (TBI) from a ^{137}Ce source (137 rad per min), 850–1,050 rad depending on mouse strain[9]. Mice, infected 24 h after irradiation, developed progressively enlarging soft colourless lesions with rounded surfaces that persisted until the time of death 10–14 d post-irradiation. Lesions in all irradiated mice, including those of 'resistant' strains, contained extraordinarily large numbers of viable treponemes and never exhibited the ulcerative appearance frequently seen in immunocompetent mice (Table 1). Highly motile organisms were readily recoverable from all lesions sampled, particularly between days 6 and 11 of infection, a time when treponemes were virtually absent in lesions of non-irradiated mice. Similarly, Warthin–Starry-stained paraffin sections of lesions revealed an intense accumulation of treponemes throughout their entire area (Fig. 2).

Table 2 Effect of irradiation and immune reconstitution on cutaneous lesions in C3H/He mice

			Challenge outcome	
Recipient	TBI (950r)	Spleen cell donor	No. of mice with lesions/ no. tested	Type of lesion
Non-immune	−	−	40/50	Healed
	+	−	40/40	Unhealed
	+	Non-immune	10/10	Healed
	−	Immune	0/10	None
	+	Immune	0/10	None
Immune	−	−	0/13	None
	+	−	9/9	Unhealed

Non-immune mice were age-matched uninfected animals. Immune mice were animals infected i.d. 23–28 d previously which developed primary lesions. As measured using an indirect fluorescent antibody procedure[11], the mean anti-treponemal antibody titre of immune mice was 32 (the reciprocal of the highest serum dilution giving positive fluorescence). Healed and unhealed lesions are as described in the text for non-irradiated and irradiated mice respectively. Syngeneic spleens were teased through a 60-mesh stainless steel screen. The cells were suspended and washed twice in Hanks' balanced salt solution. Cell viability was >95% as determined by Trypan blue exclusion. Animals were reconstituted with either 8×10^7 nucleated non-immune cells given intraperitoneally, or 4×10^7 nucleated immune cells given intravenously.

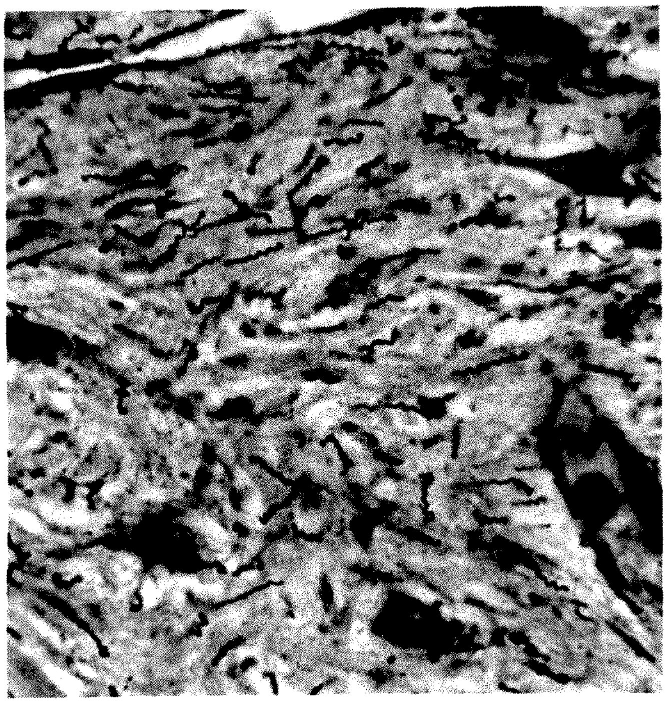

Fig. 2 Warthin–Starry-stained section of an 8-d lesion from an infected irradiated C3H/He mouse (×930). The pronounced accumulation of spirochetes in the absence of appreciable pathology is typical of lesions examined in all strains of irradiated mice (5 mice per strain). [Warthin–Starry-stained sections of lesions from non-irradiated mice reveal a gradual reduction in the number of spirochetes until day 5 of infection, after which no organisms are identifiable.]

Immunological involvement was further demonstrated by reconsituting C3H/He mice with syngeneic spleen cells within 2 h of irradiation, a procedure which not only altered the course of lesion development (Table 2, Fig. 1), but also prevented radiation death. Recipients of non-immune spleen cells, when infected 2–3 d later, developed indurated crusted lesions, similar to those seen in infected non-irradiated animals, and healing within 11 d. However, irradiated mice infected 24 h after reconstitution (data not shown) developed lesions which, like those of irradiated unreconstituted mice, progressed until day 7 of infection, except that they then became indurated and ulcerated, requiring an additional 10–12 d to heal. In these conditions, it seems that treponemes became firmly established in cutaneous tissues before immune function was restored, resulting in a biphasic lesion morphology. Collectively, these results indicate that potentiation of treponemal infection in irradiated mice is primarily the result of abrogating the immune response. As shown in Table 2, recipients of immune spleen cells, with or without preceding irradiation, are protected against any type of lesion development after i.d. challenge. However, irradiation of immune mice reestablishes their susceptibility and, when challenged, they develop large papular lesions, rich in motile treponemes, and identical to those produced in non-immune irradiated mice. Note that irradiation had no detectable effect on existing anti-treponemal antibody levels in immune mice when tested 10 d post-irradiation (Table 2).

This study points to two distinct roles for CMI during local *T. pallidum* infections. First, it undoubtedly is responsible for the characteristic pathogenesis of primary lesions as has been suggested from previous studies of treponemal infections in rabbits immunosuppressed with cyclophosphamide or cortisone[8,10]. By combining irradiation of the murine host with immune reconstitution, we have obtained direct evidence for the immune-mediated basis of these lesions. Second, the cellular component of the anti-treponemal immune response seems to be required for both the resolution of local infection and protection against subsequent i.d. challenge; its absence permits treponemes to thrive at the site of infection with only minimal tissue damage. We consider this model to have much potential application to the study of syphilis immunobiology since it should enable the identification of *T. pallidum*-specific effector cells and permit their functional activity to be defined *in vivo*. It may also serve as a new tool for evaluating both the virulence of different strains of *T. pallidum* and the immunoprophylactic value of potential non-infectious syphilis vaccines, including purified treponemal antigens. Finally, the model lends itself to further studies of host genetic factors in disease susceptibility.

Requirement for monocytes in the spontaneous cytotoxic effects of human lymphocytes against non-lymphoid target cells

J. E. de Vries*, J. Mendelsohn & W. S. Bont*

Division of Hematology/Oncology, University of California San Diego, La Jolla, California 92093

Human lymphocytes have been shown to lyse *in vitro* a large variety of target cells derived from tumour as well as normal tissues[1,2]. The effector cells involved in this spontaneous cell-mediated cytotoxicity (SCMC) have generally been characterised as lymphocytes which lack surface membrane immunoglobulin (sIg) and lack or express only low-affinity receptors for sheep red blood cells (SRBC), but possess receptors for the Fc portion of IgG (refs 3–7). We have previously shown that monocytes may be involved in SCMC, as strong depletions of adherent cells always resulted in a reduction in SCMC[8]. In the present study, experiments were undertaken to determine the role of monocytes in SCMC. Evidence is presented that monocytes have a helper function in the lymphocyte-mediated SCMC against target cells growing in monolayer cultures, whereas effector cells in SCMC against lymphoid target cells growing in suspension cultures were lysed by lymphocytes in the absence of monocytes.

SCMC was tested in a 16-h ^{51}Cr-release assay against target cells from T-24 bladder carcinoma, NKI-1 and NKI-10 melanoma, and EK embryonic kidney cell lines, growing in monolayers, and in a 4-h ^{51}Cr-release assay on lymphoid target cells from K562 (myeloid leukaemia) and Molt-4 (T-cell leukaemia) growing in suspension cultures. All cultures and tests were carried out in Dulbecco's modified Eagle's minimal essential medium (DMEM) supplemented with antibiotics and 10% fetal calf serum (FCS). Ficoll/Hypaque-isolated mononuclear leukocytes from peripheral blood, very pure lymphocyte fractions (LF) and highly enriched monocyte fractions (MF) were used as effector cells. The LF and MF were obtained by separating the Ficoll/Hypaque-isolated mononuclear leukocytes according to size by velocity sedimentation at unit gravity in a LACS-II apparatus[9]. Both fractions are characterised in Table 1.

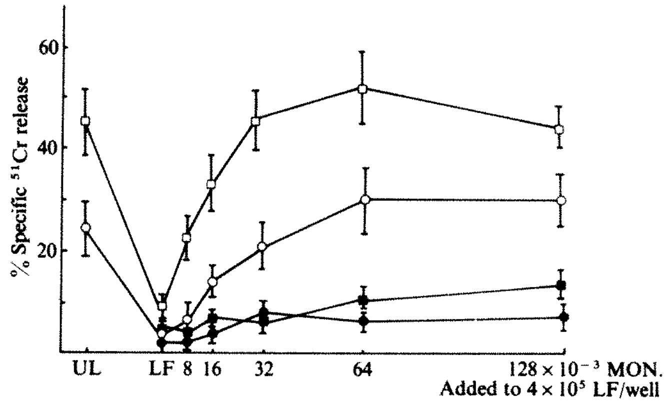

Fig. 1 Restoration of SCMC with autologous monocytes (mean ± s.e.m. of four experiments). 10^6 Monocytes were incubated for 3 h at 37°C in 1 ml culture medium containing 300 μg carrageenan under constant shaking. Before testing, the monocytes were washed three times by centrifugation. □, T-24; ○, NKI–1; ■, LF tested on T-24 after addition of carrageenan-treated autologous monocytes; ●, LF tested on NKI–1 after addition of carrageenan-treated autologous monocytes.

Compared with the corresponding unfractionated mononuclear leukocytes (UL), the LF and MF of 14 different healthy donors showed markedly reduced SCMC against the monolayer targets. In contrast, LF cells were nearly as effective as the corresponding UL in SCMC against K562 and Molt-4 target cells growing in suspension cultures, whereas the MF cells were insignificantly or weakly cytotoxic for these targets.

To investigate whether the loss of SCMC of the LF against monolayer targets could be attributed to the monocyte depletions, reconstitution experiments were carried out with autologous MF cells (Fig. 1). Addition of approximately 2% monocytes to LF cells resulted in significantly increased SCMC, whereas 8–15% monocytes were sufficient to restore the SCMC to the level achieved with the corresponding UL. Optimal induction of SCMC was observed after addition of 15–30%

Table 1 Characterisation of leukocyte fractions

	UL	LF	MF
Sedimentation velocity	—	20–36 mm h^{-1}	50–62 mm h^{-1}
% Monocytes (esterase)	23 ± 4	0.2	83 ± 4
% Monocytes (phagocytosis)	20 ± 5	<0.1	79 ± 5
% Monocytes (electronic sizing)	22 ± 4	—	81 ± 4
% Lymphocytes	77 ± 5	99.8	16 ± 4
% Lymphocytes forming SRBC rosettes	51 ± 6	56 ± 6	9 ± 3
% Lymphocytes with Fc receptors	15 ± 3	17 ± 4	10 ± 3
% Lymphocytes with C_3 receptors	18 ± 4	20 ± 3	5 ± 2
% Lymphocytes with sIg	6 ± 1	7 ± 2	3 ± 1
Granulocytes (basophils)	<0.5	0	1

Characterisation of the UL, LF and MF (mean ± s.d. of five different donors). The different criteria used to characterise the UL, LF and MF were described previously[10]. In all instances, at least 300 cells were counted. For estimating the monocyte contamination of the LF, up to 5,000 cells were screened. Of the lymphocytes present in the cell sample, 60% were recovered in the LF, whereas approximately 40% of the monocytes were obtained in the MF.

SCMC (mean % of specific ^{51}Cr release ± s.e.m.) of UL and corresponding LF and MF from 14 different healthy donors was tested on T-24, NKI-1 and MKI-10 target cells. Six different donors were tested on EK, K562 and Molt-4 target cells. The ^{51}Cr-release assays on monolayer targets (T-24, NKI-1, NKI-10 and EK) were carried out in Microtest II plates (Falcon, no. 3040 F). Confluent monolayers of target cells were trypsinised. Target cells 5,000 per well were plated in 0.2 ml culture medium and incubated overnight at 37°C and 5% CO_2, and then 4 μCi ^{51}Cr was added to each well. After 4–6 h incubation, the target cells were washed three times and 0.2 ml of effector cells in culture medium was added in the concentrations indicated. Effector and target cells were incubated for 16 h after which 100 μl supernatant was collected and counted. The ^{51}Cr-release assays on K562 and Molt-4 target cells (growing in suspension cultures) were carried out in U-bottomed Linbro plates (no. 76-213-05). In these, 10^4 ^{51}Cr-labelled target cells (100 μl) were mixed with the appropriate number of effector cells (in 100 μl), centrifuged for 2 min at 150*g* and incubated for 4 h at 37°C and 5% CO_2. At the end of the incubation 100 μl supernatant was collected and counted. The specific ^{51}Cr release was calculated by the following formula: % cytotoxicity = (test ^{51}Cr release − spontaneous ^{51}Cr release)/(total amount of ^{51}Cr incorporated into the targets − spontaneous ^{51}Cr release). The average spontaneous ^{51}Cr release ± s.d. was: T-24 = 18 ± 3; NKI-1 = 15 ± 3; NKI-10 = 13 ± 3; EK = 20 ± 4; K562 = 9 ± 2; Molt-4 = 12 ± 2.

monocytes. MF cells in the absence of LF cells were not cytotoxic. Intact, paraformaldehyde-killed monocytes were ineffective in inducing SCMC (not shown).

As the MF used as monocyte source for our reconstitution experiments contained 15–20% lymphocytes, it was possible that the induction of SCMC was mediated by these non-cytotoxic lymphocytes present in the MF. To evaluate this possibility, the MF cells were preincubated with carageenan, which selectively kills monocytes[11]. The carrageenan-treated monocytes caused no induction of SCMC after addition to the LF (Fig. 1), suggesting that the helper effects were mediated by monocytes and not by the contaminating lymphocytes in the MF. Lymphocytes were not affected by the carrageenan treatment, because LF cells preincubated with carrageenan showed good responses to mitogens after addition of autologous monocytes (J.E.d.V. and L. Holley, unpublished findings). Having demonstrated that SCMC on target cells growing in monolayer cultures required the presence of viable monocytes, we next tried to determine whether soluble factors produced by cultured monocytes could induce SCMC by LF cells. Figure 2 shows that supernatants of allogeneic monocyte cultures added to LF cells induced significant SCMC, although this was always weaker than the SCMC achieved with viable autologous monocytes and never exceeded 60% of the SCMC obtained with the corresponding UL. Monocytes or monocyte culture supernatants (MCS) could not be replaced by 2-mercaptoethanol (2-ME), which also had no supplementary effect on the restorative effects of MCS.

The effector cells in SCMC against non-lymphoid target cells growing in monolayers have previously been characterised as non-SRBC-rosette forming, sIg-negative, FcR^+ lymphocytes[7,13]. FcR^+ lymphocytes were also found to be the actual effector cells in monocyte-induced SCMC by LF cells, because addition of autologous monocytes to LF cells depleted in FcR^+ lymphocytes resulted in insignificant induction of SCMC (results not shown).

These results suggest that viable monocytes or soluble monocyte products are required for FcR^+-lymphocyte-mediated SCMC against non-lymphoid target cells growing in monolayer cultures. Reconstitution with very low monocyte concentrations was sufficient to induce significant SCMC. This may explain why conventional monocyte depletion procedures, because they generally result in incomplete monocyte removal, failed to demonstrate the requirement of monocytes in SCMC measured in 16-h ^{51}Cr-release assays.

The finding that LF cells were completely able to kill K562 and Molt-4 cells in the absence of monocytes (Table 2) suggests that distinct types of effector cell are involved in the killing of target cells growing in monolayers and target cells of lymphoid origin growing in suspension cultures (the former requiring monocyte help, the latter independent of it). Our findings are consistent with the results of Timonen and Saksela[12], who demonstrated that depletion of lymphocytes which were cytotoxic for fetal fibroblasts growing in monolayer cultures did not result in reduction of SCMC against lymphoma (Raji) and leukaemia (Molt-4, K562) cell lines. This indicates that different effector cell populations may be involved in SCMC against monolayer targets and lymphoid target cells growing in suspension cultures. Such a possibility is further supported by the finding that, in contrast to the effector cells active in SCMC against monolayer targets[7,13], the effectors in SCMC against K562 may possess low-affinity receptors for SRBC[6]. However, the extent to which the monocyte-independent SCMC against K562 and Molt-4 is related to the lymphoid origin and sensitivity of these cells remains unknown.

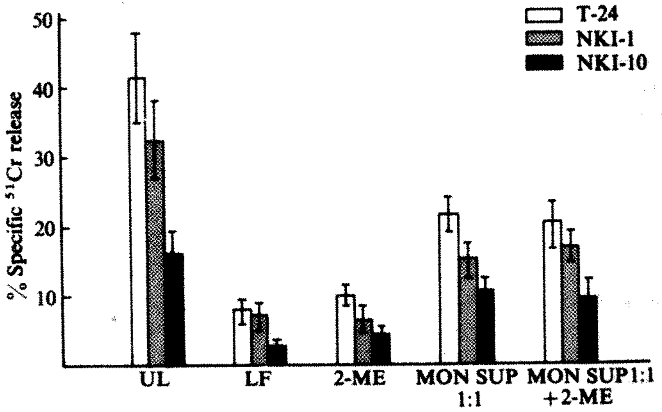

Fig. 2 Restoration of SCMC of LF cells by allogeneic monocyte culture supernatant (MCS). MCS was obtained from cultured MF cells. 4×10^5 MF cells in 0.2 ml DMEM + 10% FCS were cultures per well in Microtest II plates (Falcon, no. 3040 F). After overnight incubation (37°C, 5% CO_2) the wells were vigorously washed to remove non-adherent cells. Fresh culture medium (0.25 ml) was added and the plates were incubated for another 72 h (in other experiments 24–48 h) (37°C, 5% CO_2). The supernatants of these confluent monocyte monolayers (>96% esterase positive) were collected, centrifuged for 10 min at 2,000*g*, filter sterilised and stored at −80°C until testing. 2-ME: = 2-mercaptoethanol (5×10^{-5} M) added to LF cells from three different donors (mean ± s.e.m.); MON SUP 1:1 = MCS 1:1 diluted in culture medium added to LF cells from three different donors (mean ± s.e.m.); MON SUP 1:1 + 2-ME = MCS 1:1 diluted in culture medium and 2-ME (5×10^{-5} M) added to LF cells (mean ± s.e.m.).

As LF cells were found to be cytotoxic for Chang liver cells in an antibody-dependent cellular cytotoxicity (ADCC) system[13], we considered the possibility that the monocyte requirement for SCMC against monolayer targets could have been mediated by antibodies synthesised in the presence of, or shed by, monocytes. It has been reported that these types of antibodies may have a role in SCMC and that SCMC actually is a form of ADCC[14–17]. However, we found that goat $F(ab')_2$ fragments of purified anti-human Fab antibodies did not significantly inhibit SCMC, suggesting that antibodies are not involved in SCMC and that SCMC and ADCC must be attributed to distinct cytotoxic events[13]. It seems more likely that the induction of SCMC by monocytes is mediated by non-Ig soluble factors, as it has been demonstrated that SCMC is enhanced by purified interferon[18] and by interferon synthesised during co-cultivation of lymphocytes with tumour cells[19,20]. Therefore, the possibility must be considered that in our system the induction of SCMC is also mediated by interferon produced either directly by monocytes or indirectly in cooperation with LF cells[21,22]. These regulatory functions of monocytes in SCMC will be further investigated.

We thank Dr Al Caviles Jr for his help and critical comments and Linda Holley, Betty Honig and Geertje de Graaf for their technical assistance. J.E.d.V. was recipient of an IUCC/ACS Eleanor Roosevelt Fellowship. J.M. was supported by grants CA11971 and CA09174 from the NIH.

T-lymphocyte differentiation is accompanied by increase in sialic acid content of Thy-1 antigen

Daniel Hoessli*, Claude Bron† & J. Richard L. Pink‡

Lymphocyte differentiation is accompanied by changes in the expression of various glycoproteins at the cell surface [1–4]. Whether changes in the structures of individual glycoproteins, as opposed to changes in their expression, also occur during this differentiation is not known. To answer this question, we have studied the structures of the Thy-1 glycoprotein isolated from mouse thymic (immature) and peripheral (mature) T lymphocytes. This glycoprotein was chosen for study because there is already evidence that the Thy-1 glycoprotein can carry different carbohydrate structures on the same polypeptide backbone[5] and because it is also known that peripheral T lymphocytes have more sialic acid and more sialyl-transferase activity than do thymocytes[6]. Barclay *et al.*[5] indeed showed that there were differences between the carbohydrate compositions of the Thy-1 antigen isolated from rat brain and thymus. We believe this to be the only clear example of tissue-specific differences in carbohydrate content of a given glycoprotein. In contrast to Barclay *et al.*, we have studied cells of a common differentiation pathway. Here we show, using a two-dimensional electrophoresis technique[7], that differentiation can involve the modification of carbohydrate structures of individual glycoproteins, as Thy-1 molecules on peripheral T cells carry more sialic acid than do thymic Thy-1 molecules. We also show that there is a charge difference (which does not involve sialic acid) between the two allelic forms, Thy-1.1 and Thy-1.2, of the antigen.

Thymocytes or mesenteric lymph node cells were prepared from AKR and BALB/c mice, which carry the *Thy-1.1* and *Thy-1.2* alleles, respectively. The cells were radio-iodinated and lysed in NP-40 detergent[8]. The Thy-1 antigen was precipitated from the lysates[9] using a rabbit antiserum prepared against a highly purified mouse thymus lymphocyte antigen (MTLA) which is identical with, or at least very similar to, the Thy-1 antigen present on thymocyte membranes[10,11].

Figure 1 shows that anti-MTLA specifically precipitates, from BALB/c thymocytes, a series of basic spots (*p*I above *p*H 7.5) differing in charge, with each spot showing apparent molecular weight (MW) heterogeneity in the range 25,000–30,000. Very similar spots are precipitated by conventional anti-Thy-1.2 alloantisera, or monoclonal rat anti-mouse Thy-1 reagents[12]. These results are in agreement with previous findings that the Thy-1 molecule is a glycoprotein of apparent MW about 25,000 (refs 5, 13).

Thy-1 antigens precipitated by anti-MTLA from thymocytes and lymph node cells of AKR and BALB/c mice are compared in Fig. 2. In both strains, the lymph node Thy-1 antigens are clearly more acidic than the thymus antigens. In the case of the lymph node, the spots are less heterogeneous in apparent MW, and the most acidic lymph node Thy-1 spots have a higher apparent MW than the least acidic. Similar results were obtained from splenic Thy-1 molecules.

The charge difference between thymocyte and peripheral cell Thy-1 molecules is entirely due to the presence of extra sialic acid in the peripheral lymphocyte antigens. As shown in Fig. 3, for AKR cells, the charge difference between thymocyte and lymph node cell Thy-1 molecules is abolished if the cells are treated with neuraminidase. The same is true for BALB/c cells (not shown). The thymocyte antigens do carry some sialic acid, as they become even more basic after neuraminidase treatment, but the amount of sialic acid on the Thy-1 of peripheral cells is clearly greater than that of thymocytes.

Almost all Thy-1 molecules on peripheral cells are more heavily sialylated than thymocyte Thy-1 (Figs 2, 3). The increase in sialylation is therefore probably not responsible for the antigenic difference reported to exist between the Thy-1 on thymocytes and a subpopulation (about 50%) of splenic T cells[14]. Moreover, neuraminidase-treated Thy-1 was readily precipitated by anti-MTLA, or a monoclonal anti-Thy-1 reagent (not shown).

Figure 2 also shows that AKR and BALB/c Thy-1 molecules differ in charge, with the AKR (Thy-1.1) spots being more basic than the corresponding BALB/c (Thy-1.2) spots. This inter-strain difference can also be seen in gels made from total lysates of iodinated thymocytes or peripheral cells, and is therefore not an artefact of the precipitation procedure. Also, Thy-1 molecules from AKR/Cum mice, which carry the Thy-1.2 specificity on an AKR background, behave like BALB/c Thy-1.2 mole-

0028-0836/80/060576—03$01.00

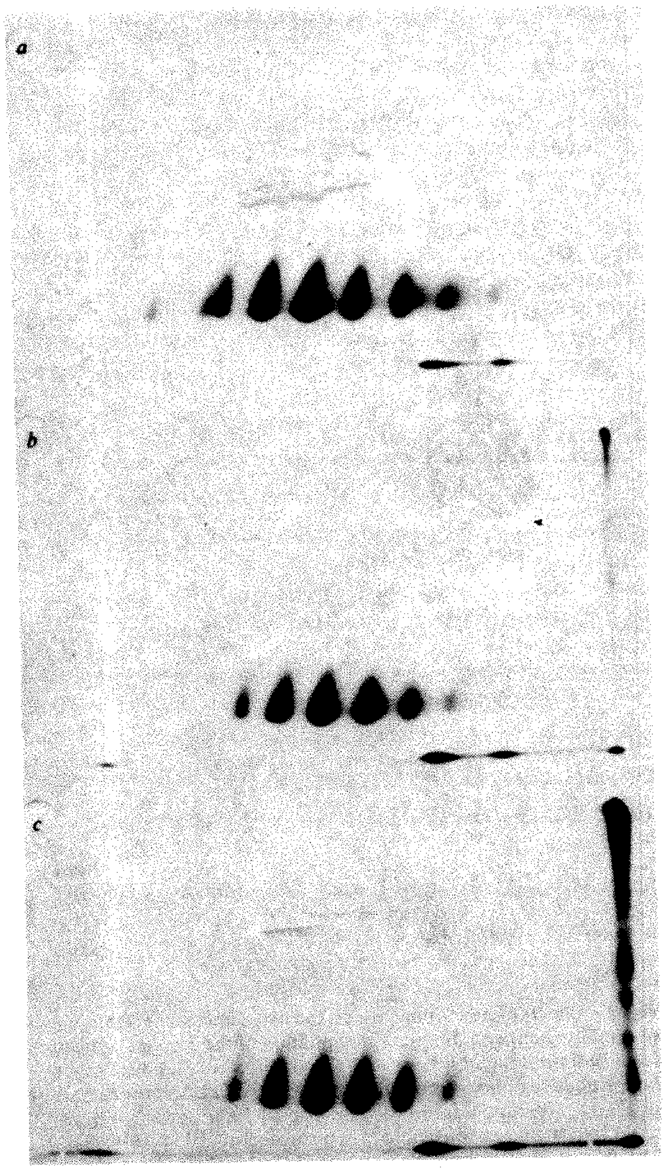

Fig. 1 Immunoprecipitation and two-dimensional gel analyses of the Thy-1.2 antigen. 50×10^6 viable BALB/c thymocytes were incubated in 1 ml of phosphate-buffered saline (PBS), 20 mM D-glucose, for 40 min at 20 °C, with 10 µg of lactoperoxidase (Sigma), 2 U of glucose oxidase (Sigma) and 1 mCi ^{125}I (NEN). After three washes in cold PBS, the labelled cells were lysed in 100 µl of PBS containing 0.5% NP-40 (v/v) and 1 mM phenylmethylsulphonyl fluoride. After a low speed centrifugation to remove nuclei, the lysate was desalted on Sephadex G-25 and the labelled macromolecular material collected in the void volume. After centrifugation at 100,000*g* for 30 min, immunoprecipitation was carried out on aliquots of lysate corresponding to 10×10^6 cells[9]. *a*, Immunoprecipitation with 5 µl anti-mouse T-lymphocyte antigen (MTLA) antiserum[10]; *b*, immunoprecipitation with 15 µl of an anti-Thy-1.2 alloantiserum (AKR anti-C3H, absorbed on AKR thymocytes) for 30 min at 20 °C, then overnight at 4 °C, followed by 25 µl of a rabbit anti-mouse Ig; *c*, immunoprecipitation with 15 µl of a rat monoclonal anti-Thy-1.2 antibody; 50 µl of a sheep anti-rat whole serum was added as a second antibody. Immunoprecipitated radioactivity was then extracted in 50 µl of O'Farrell's isoelectric focusing buffer and run in non-equilibrium *p*H gel electrophoresis (NEPHGE)[7] conditions. 10% polyacrylamide slab gels were used for the second dimension. Dried slab gels were exposed for 15–30 days to X-Omat R films (Kodak) with an intensifying screen. The basic end is at the left and the acidic end at the right of each panel, where the sample was loaded.

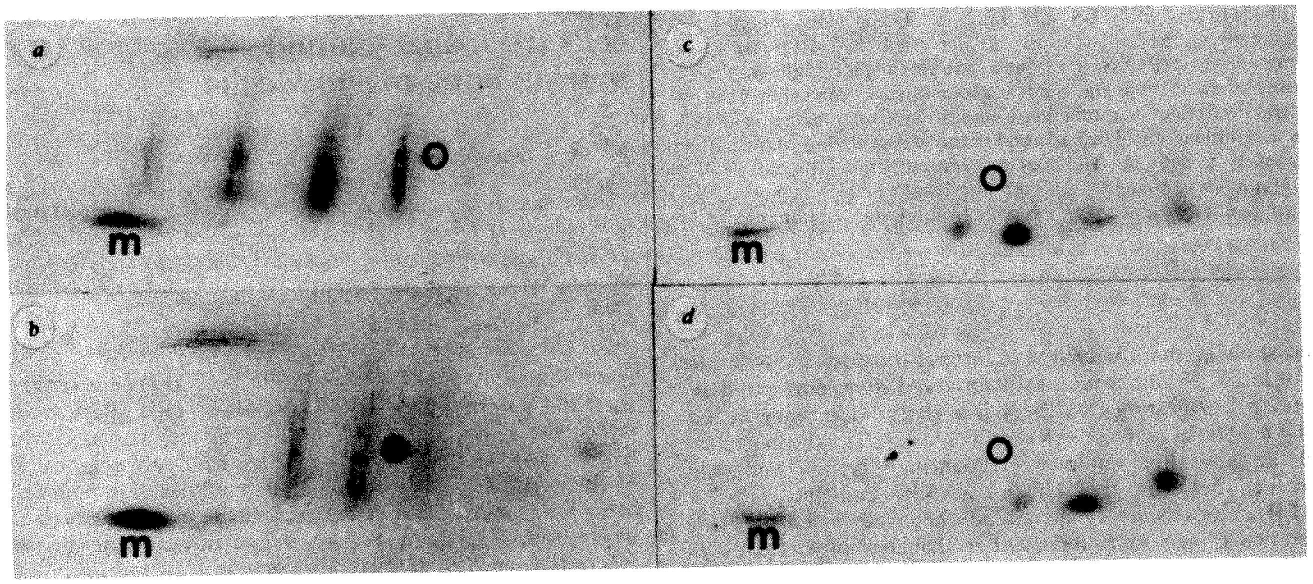

Fig. 2 Two-dimensional mapping of the Thy-1.1 and Thy-1.2 antigens. Thymocytes and mesenteric lymph node lymphocytes of AKR (Thy-1.1) origin were radio-iodinated and lysed as in Fig. 1. Lysates corresponding to 10×10^6 cells were immunoprecipitated[9] with 5 µl of anti-MTLA antiserum[10]. Immunoprecipitated Thy-1 molecules were mixed with selected isoelectric point and MW markers (m and o) labelled with ^{35}S-methionine in the isoelectric focusing buffer of O'Farrell and run in NEPHGE[7] conditions. Second-dimension gels and autoradiography were carried out as in Fig. 1. Only a portion of each autoradiogram is shown, orientated as in Fig. 1. *a*, AKR thymocytes; *b*, BALB/c thymocytes; *c*, AKR mesenteric lymph node lymphocytes; *d*, BALB/c mesenteric lymph node lymphocytes.

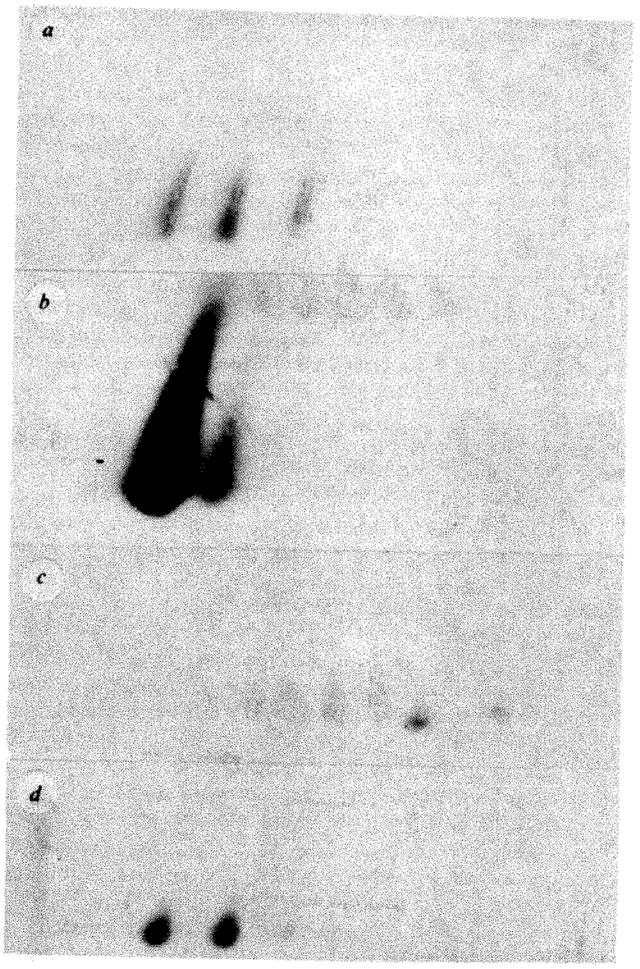

Fig. 3 Effects of neuraminidase on the two-dimensional mapping of the Thy-1 antigen. Immunoprecipitation of the Thy-1.1 antigen from radio-iodinated lysates of AKR thymocytes and mesenteric lymph node lymphocytes was done using anti-MTLA antiserum, as in Fig. 1. Neuraminidase (*Vibrio cholerae*, Behringwerke) treatment was carried out on whole cells by incubating 100×10^6 cells in 2 ml of Tris-HCl 10 mM, *p*H 6.0. NaCl 0.14 M, $CaCl_2$ 10 mM with 0.1 IU of enzyme per ml for 60 min at 37 °C. Treated cells were washed twice with PBS and radio-iodinated. Neuraminidase treatment in these conditions did not result in a decrease in lymphocyte viability. Second-dimension gels and autoradiography were carried out as in Fig. 1. Portions of autoradiograms shown are aligned on minor neuraminidase-insensitive contaminants in the immunoprecipitate. The basic end of the *p*H gradient is to the left of each panel. *a*, Thymocytes, untreated; *b*, thymocytes, neuraminidase treated; *c*, mesenteric lymph node lymphocytes, untreated; *d*, mesenteric lymph node lymphocytes, neuraminidase treated.

cules, showing that the charge difference is associated with the *Thy-1* locus. The difference is still observed after neuraminidase treatment, suggesting that there is a charge difference at the amino acid level between AKR and BALB/c Thy-1 molecules. Such an alteration could be responsible for the antigenic difference between the Thy-1.1 (AKR) and the Thy-1.2 (BALB/c) molecules. It has already been suggested that this difference is due to protein rather than carbohydrate polymorphism[5], but a role for carbohydrate in Thy-1 antigenicity[15] is not excluded.

It is not clear whether changes in the carbohydrate structure of given glycoproteins commonly accompany cellular differentiation. At least one other group of T-cell high MW glycoproteins also undergoes increased sialylation during T-lymphocyte maturation[16], but not every lymphocyte glycoprotein is modified when the cell leaves the thymus (D.H., P. Vassalli and J.R.L.P., in preparation). The increased sialylation of the Thy-1 and high MW glycoproteins cannot by itself account for the increased sialic acid content of peripheral T cells, both because peripheral lymphocytes carry less Thy-1 than do thymocytes[3], and because the number of Thy-1 and high MW glycoprotein molecules per peripheral cell ($<10^6$)[3] cannot completely account for the difference in sialic acid content between the two cell types ($>2 \times 10^7$ molecules per cell)[6].

The overall increase in sialic acid content of peripheral T cells may be functionally significant. Woodruff and Gesner[17] have shown that neuraminidase-treated peripheral lymphocytes do not home to lymphoid organs when injected intravenously into syngeneic hosts, but are quickly trapped in the liver. Moreover, normal, poorly sialylated thymocytes do not home efficiently to peripheral lymphoid organs[18]. Changes in the structure of glycoprotein carbohydrates may be as important for cellular function as the quantitative changes which occur in the amounts of cell-surface glycoproteins during lymphocyte maturation[1–4].

This work was supported by a grant from the Swiss NSF. We thank Dr P. Vassalli for helpful discussion. Rat monoclonal antibody was supplied by Dr F. Fitch, and guinea pig pancreatic secretion products by Dr A. Tartakoff.

Autoreactive natural killer-like cells from agar-cloned murine bone marrow cells

M. H. Claësson*† & L. Olsson‡

† University of Copenhagen, Panum Institute, Anatomy Department A, 3, Blegdamsvej, DK-2200 Copenhagen

‡ Department of Tumor Virus Research, Institute of Medical Microbiology, 30, Juliane Mariesvej, DK-2100, Copenhagen, Denmark

Natural surveillance against malignant cells has been ascribed to so-called natural killer (NK) cells. These cells attack tumour cells without prior antigen stimulation and may also be cytotoxic to non-malignant cells[1,2]. NK cells are routinely demonstrated by their cytotoxic activity against various types of tumour cell *in vitro*, but elucidation of the characteristics of the cytotoxic cells has hitherto been hampered by the lack of techniques by which NK cells can be isolated. Here we demonstrate murine NK-like activity from bone marrow cells cloned in semi-solid agar medium for granulocyte–macrophage colony formation. Data obtained indicate that such procedures considerably improve the possibility of obtaining quite pure NK cell populations by which the NK cell phenomenon may be studied in more detail.

Dose–response data for the cytotoxicity of mass-collected cluster and colony cells from day 7 cultures show (Table 1) that a variety of syngeneic, allogeneic and xenogeneic tumour cells as well as fetal syngeneic fibroblasts are sensitive to cytotoxic attack in a ratio of target : attacker cell as low as 1 : 0.2 to 1 : 0.1. The human Burkitt lymphoma cell line (Raji) was resistant to killing, but all other tumour lines examined were sensitive. The most sensitive targets were the syngeneic YAC-1 tumour cell line and the malignant cell line from metastatic foci of the allogeneic Lewis lung tumour model described recently[3].

Table 1 Cytotoxicty of mass-collected cluster and colony cells against syngeneic fibroblasts and syngeneic, allogeneic and xenogeneic tumour cell lines

Target cells	Target: attacker cell ratio 1:2	1:0.66	1:0.20	1:0.10	1:0.04
Fetal fibroblasts	48%*	39%	38%	20%	NS
YAC-1 (BALB/c)	40%	41%	41%	37%	27%
NS-1 (BALB/c)	27%	20%	21%	26%	NS
BW 5147 (AKR)	16%	19%	18%	NS	NS
Lewis lung (C57B1) metastatic foci	18%	17%	14%	NS	NS
Lewis lung primary tumour	57%	39%	41%	15%	NS
Raji (human) (Burkitt lymphoma)	NS	NS	NS	NS	NS
Molt-3 (human) (T-leukaemia)	21%	21%	24%	NS	NS

The cytotoxic properties of cluster and colony cells, that is, aggregates composed of less or more than 50 cells, from 7-d bone marrow cultures with 2×10^5 cells per ml agar medium[9]. Mice were 2–3 months old BALB/c. Colony-stimulating factor (GM-CSF) was a fivefold concentrated supernatant from concanavalin A stimulated sileen cells[10]used in a concentration of 1.25%. Cluster and colony cells were mass collected by mechanical disruption of the agar in serum-free RPMI-1640 medium. The agar was removed by centrifugation over fetal calf serum (FCS) at 1,000*g* and the pelleting cells were washed twice and counted for viability before assay. When individual colonies were assayed they were transferred from the agar to 0.4 ml RPMI-1640 medium by a Pasteur pipette and dispersed by pipetting. The cytotoxic properties of the collected cells were tested in a 4-h ^{51}Cr-release assay[11]. The malignant cell lines and non-malignant embryonic BALB/c fibroblasts in their second passage were labelled with ^{51}Cr and used as target cells. Briefly, fivefold replicate cultures of 10^4 target cells in 0.1 ml RPMI-1640 medium labelled with ^{51}Cr were added to wells of 96-well microplates followed by addition of 0.1 ml attacker cells in appropriate number according to the target: attacker cell ratio. When individual colonies were assayed cultures were run in duplicates and the target cell number was 5,000. The supernatant of each well was collected 4 h later and the ^{51}Cr content determined. Total release was determined by addition of distilled water to some wells. Spontaneous release was determined by release in wells containing only ^{51}Cr-labelled target cells. Spontaneous release was 10–15% of total release. s.e. values were about 5–10%. The specific release was calculated as: [(counts in experiment − counts in sponetaneous release)/(total release − spontaneous release)] × 100. In fivefold replicate cultures specific release more than 10% was significant at $P < 0.01$ level. In duplicate cultures (assay of single colonies) specific release was considered significant when equal to or more than 20%.

* Specific ^{51}Cr release, mean of fivefold replicate cultures.

Table 2 shows the kinetics of appearance of cytotoxic activity in relation to duration of culture. The cytotoxic activity was highest on days 6–7 of culture and no autoreactivity was detected on days 4 and 12.

Mass-collected cluster and colony cells obtained on day 7 were separated according to the presence or absence of Fc receptor and the cytotoxicity tested (Table 3). Only the Fc receptor-negative cell population was cytotoxic. Table 3 also shows that mature granulocyte colony cells collected from day 8 cultures were without cytotoxic effect. Similarly, bone marrow cells cultured in liquid medium in the presence of concanavalin A and tested for cytotoxicity after 4–11 d of culture showed no cytotoxic activity. Both mass-collected mouse B-lymphocyte colony cells and human T-lymphocyte colony cells were without cytotoxic activity. Table 3 includes results obtained with normal and activated adherent mouse peritoneal cells. None of these cell categories was cytotoxic. Finally, Table 3 shows that the cytotoxic activity of mass-collected cluster and colony cells from bone marrow cultures was lost by freeze-thawing the attacker cells before assay.

Of 115 single colonies from day 6–7 bone marrow cultures assayed individually (Table 1 legend) for cytotoxicity against both YAC-1 tumour cells and fetal syngeneic fibroblasts, 16 cytotoxic colonies were detected. Of these, 14 were cytotoxic to YAC–1 tumour cells (mean specific ^{51}Cr release 31%, range 23–40%) and nine of the colonies were cytotoxic to syngeneic fibroblasts (mean specific ^{51}Cr release 26%, range 20–38%). Seven of the colonies were cytotoxic to both tumour cells and fibroblasts. Four replicate agar cultures containing 2×10^5 bone marrow cells per culture were typed at day 7. Individual colonies were transferred to microscopic slides, fixed in glutaraldehyde (2.5%) and stained with Mayer's haematoxylin followed by Giemsa staining. Of these colonies 66% were of the mononuclear–macrophage type, including the dispersed type of colonies described below, 16% of the colonies were composed mainly of polymorphs and 18% were typical mixed macrophage–granulocyte colonies (Fig. 1). The cultures contained fivefold as many clusters which were not typed.

In separate experiments, morphology and cytotoxicity of individual colonies were studied simultaneously. Half of the colony was fixed and stained as above and the other half was assayed for cytotoxicity. The colony type that most often showed cytotoxic activity appeared in the agar as very dispersed aggregates composed of uniform, small cells (Fig. 1*a*). The cell number in these colonies at day 7 of culture was 500–1,000. Differential counts of five cytotoxic colonies of the dispersed type revealed that 64 ± 18% of the colony cells were small, mononuclear cells with a diameter below 10 μm. The cytoplasm of these cells was pale and contained a few small nonspecific granules but no phagocytosed agar. In contrast, the few mature macrophages (6 ± 5%) present in these cytotoxic colonies all contained large spheres of phagocytosed agar in their cytoplasm. In all the cytotoxic dispersed colonies a considerable number of polymorphs were present. The dispersed type of cytotoxic colonies constituted 3–4% of all colonies at day 7 of culture. More rarely, cytotoxic cells were present in colonies which appeared in the agar as composed of macrophages only or macrophage–granulocyte mixtures (compare Fig. 1*b*, *c*). However, in these colonies the small mononuclear cell type described above was always present in significant numbers.

Table 2 Cytotoxicity of mass-collected cluster and colony cells after different periods of culture against YAC-1 tumour cells and syngeneic embryonic fibroblasts (Fib)

Days of culture	Target: attacker cell ratio 1:1		1:0.33		1:0.10		1:0.05		1:0.02

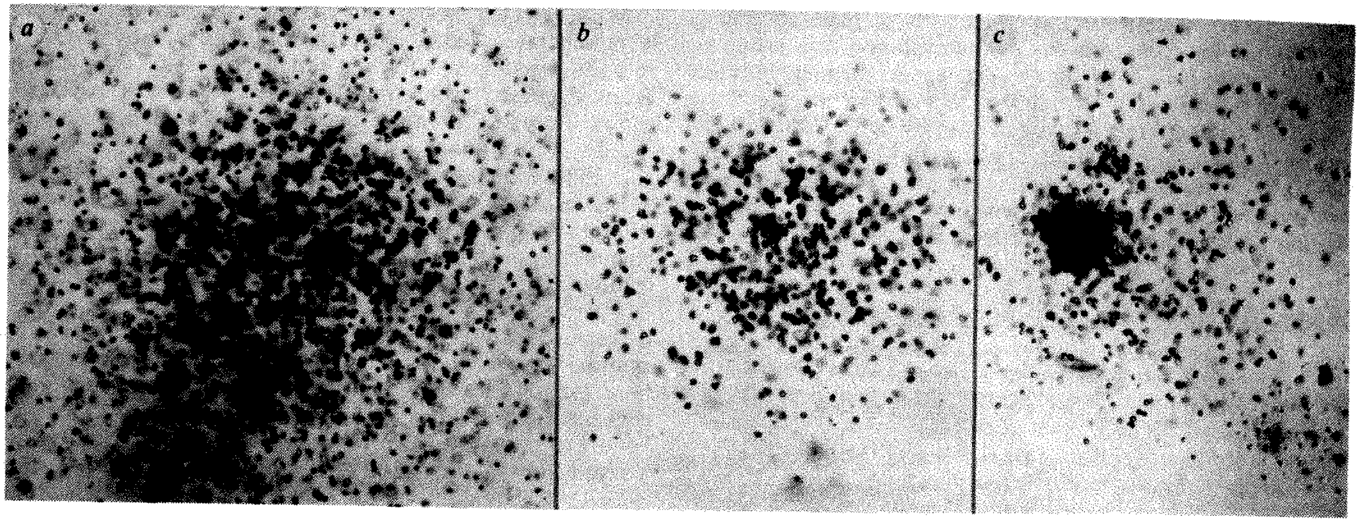

Fig. 1 *a*, A Colony with cytotoxic activity photographed in the agar medium. Note the uniform size of the very dispersed colony cells. *b*, A typical macrophage colony. *c*, A mixed macrophage–granulocyte colony. ×15.

The present results clearly demonstrate that cells with an autocytotoxic effect and with NK-like activity can be grown on a clonal basis from bone marrow cells stimulated by GM-CSF in agar medium. Clones with cytotoxic activity contain in addition to typical polymorphs and macrophages a substantial number of small mononuclear cells. It is known that both macrophages and polymorphs derived from GM colonies possess the Fc receptor[4], whereas the cytotoxic cell in the present study was Fc receptor negative. Moreover, cytotoxicity was not detected in mature macrophages or polymorphs. Taken together, our results suggest that the cytotoxic cell should be sought among the small mononuclear cells most frequently present in the cytotoxic colonies of the undifferentiated, dispersed type.

Previous studies have shown that mouse NK cells are non-adherent, non-phagocytic cells lacking the Fc receptor for IgG (ref. 5). The NK cell also lacks surface receptors typical for B and T lymphocytes[6], but has been suggested to belong to a pre-T-lymphoid subpopulation[1]. The present culture system is presumed only to permit proliferation of non-lymphoid precursor cells, that is, GM-colony forming cells[7]. However, it remains to be proven that non-B, non-T-lymphoid cells cannot proliferate and differentiate to a certain degree (without gaining receptors typical of mature lymphocytes) in the present agar culture system. Therefore, we cannot exclude the possibility that the cells with NK-like activity might be subsets of lymphoid cell precursors.

Table 3 Cytotoxicity of different cell populations against YAC-1 tumour cells and syngeneic embryonic fibroblasts (Fib)

$^+$ Specific release, mean of fivefold replicate cultures.

We have previously shown that activated autoreactive cells possess the Fc receptor[3], and recently it was shown that NK cells which had been activated *in vitro* may also be Fc receptor positive[8]. The non-activated cytotoxic cell of the present study was Fc receptor negative. It is therefore possible that NK cells and cytotoxic autoreactive cells not only belong to the same subset of cytotoxic cells but also represent different differential steps eventually within the same clone of cytotoxic cells, as seven out of nine autoreactive colonies detected in the present study also showed cytotoxicity against tumour cells.

In conclusion, it is possible to detect cytotoxic clones by their morphology in agar and it should thus be possible by this technique to obtain highly purified preparations of the cells with both cytotoxic autoreactivity and NK-like activity. This will improve the possibility for a complete phenotypic characterisation of the effector cells and their natural biological function.

This study was supported by grants from the Danish Cancer Society and the Danish MRC.

Direct cloning and extended culture of antigen-specific MHC-restricted, proliferating T lymphocytes

Benjamin Sredni, Harley Y. Tse & Ronald H. Schwartz

Laboratory of Immunology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20205

The development of antigen-specific, T-cell lines has been a subject of intensive investigation by many laboratories interested in the problems of the nature of the T-cell receptor and the mechanism of major histocompatibility complex (MHC) restriction. We describe here a modification of the soft agar cloning technique which has allowed us to rapidly generate and expand proliferating T-lymphocyte clones directly from murine lymph nodes. Using this technique, we demonstrate that such T-cell clones are antigen specific and require I–A compatible antigen-presenting cells for stimulation.

Analysis of the B-cell repertoire of antigen-specific receptors has been greatly facilitated by the availability of monoclonal antibodies from both myeloma tumours[1] and hybridomas[2]. In contrast, little is known about either the constant regions or the antigen-combining properties of the receptors of T lymphocytes. Some progress has been made with the use of anti-idiotypic antibodies as probes for examining individual families of T-cell receptors among whole T-cell populations[3] and through direct isolation in small quantities of hapten-binding receptors[4]. Clearly, however, analysis of the T-cell repertoire would be greatly facilitated by the ready availability of large quantities of clonal products. The early observations of Ben-Sasson *et al.*[5] indicated that specific enrichment of proliferating guinea pig T cells could be achieved using repeated stimulation with antigen-pulsed macrophages. Ruscetti *et al.*[6] then demonstrated that T lymphocytes from human peripheral blood could be maintained in long-term cultures if the growth medium was supplemented with supernatants from mitogen-stimulated lymphocytes. These studies were extended by Gillis and Smith[7] who were able to propagate both human and murine cytotoxic T lymphocytes. Recently this approach has been applied to antigen-specific T helper cells to isolate cells specific for keyhole limpet haemocyanin (KLH)[8] and sheep red blood cells[9]. Although such long-term T-lymphoblast cell lines were enriched for either alloreactive or helper T cells, they did not constitute clones of antigen-specific cells. Sredni *et al.*[10] developed a technique for cloning mitogen-stimulated T lymphocytes in soft agar and Nabholz *et al.*[11] and Fathman and Hengartner[12] used this technique to clone alloreactive murine T cells from long-term T-lymphoblast cell lines; however, the clones often lost the capacity to mediate cytotoxicity. Recently, long-term cytotoxic cell lines have been successfully cloned by limiting dilution techniques[13]. Although these results represent significant advances in the development of monoclonal populations of T lymphocytes, it has not previously been possible to directly isolate from the animal a large number of antigen-specific T-cell clones which could be reliably expanded for analysis of function and specificity.

Fig. 1 A colony of proliferating T lymphocytes derived from a single B10.A lymph node cell specific for DNP-OVA. The cells were cloned in soft agar as described in Table 1. After expansion in liquid culture (Table 2) cells from this colony were all shown to be T lymphocytes by indirect immunofluorescent staining on the fluorescence activated cell sorter using a hybridoma anti-Thy.1 reagent and a fluorscein-labelled rabbit F(ab')$_2$ anti-mouse immunoglobulin.

Primed lymph node cells from C57BL/10 congeneic mice bearing different H–2 haplotypes were cloned in soft agar as described in the legend to Table 1. A typical colony is shown in Fig. 1. The number of colonies obtained was similar for all three antigens tested—dinitrophenyl-ovalbumin (DNP-OVA), poly(Glu^{60}Ala^{30}Tyr^{10}) (GAT), and purified protein derivative of tuberculin (PPD). This clonal frequency was approximately 20 to 30 colonies per 2×10^6 cells plated or 1 to 1.5×10^{-5}. However, the colonies elicited by the different antigens were independent of one another as shown in Table 1 by the additive

Table 1 Cloning of proliferating T lymphocytes

Mouse strains	Priming antigen	Antigen *in vitro*	No. of colonies per 2×10^6 cells seeded*	Clonal frequency
B10	GAT in CFA	GAT	21 ± 3	1.1×10^{-5}
B10	GAT in CFA	PPD	32 ± 3	1.6×10^{-5}
B10	GAT in CFA	GAT+PPD	52 ± 4	2.6×10^{-5}
B10.S	GAT in CFA	GAT	2 ± 0.3	1.0×10^{6}
B10.S	GAT in CFA	PPD	31 ± 4	1.6×10^{-5}
(B10.S×B10)F$_1$	GAT in DFA	GAT	20 ± 3	1.0×10^{-5}
B10.A	DNP-OVA	DNP-OVA	24 ± 2	1.2×10^{-5}

B10 congeneic mice were primed in the hind footpads and at the base of the tail with 50 μg ml^{-1} DNP-OVA or GAT in Freund's complete adjuvant (CFA) containing H37Ra[17]. Inguinal and popliteal lymph nodes were aseptically removed 7–10 d later. Single cell suspensions were prepared and passed over nylon wool columns[14,17]. The nonadherent cells (2×10^6) were stimulated in Costar plates (no. 3524) with soluble antigen (100 μg ml^{-1}) in the presence of syngeneic irradiated (2,000 R) spleen cells (5×10^5) as a source of presenting cells[16] in a final volume of 1 ml of Click's medium[17] supplemented with 10% heat-inactivated fetal calf serum (FCS). After 3 d of culture the cells were collected, washed and cloned in soft agar in 30-mm Petri dishes[10]. The lower agar layer consisted of 2.5 ml of Click's medium supplemented with 20% FCS, 0.5% Noble agar and 20–100 μg ml^{-1} antigen. The upper layer consisted of 2×10^6 T cells in 0.85 ml of the same medium but containing 0.32% agar. The dishes were incubated at 37°C in a humidified atmosphere with 5% CO_2 for 3–5 d. During this time the majority of seeded cells died while a small number grew out into colonies, each consisting of at least 50 cells. The values presented were represent the arithmetic mean of three separate experiments.

TNP-KLH	100	44 (±8)	33 (±5)	0	0

Colonies were picked from soft agar using a stereo-microscope. They were placed in flat-bottomed, microtitre wells in Click's medium along with 1×10^4 irradiated syngeneic spleen cells, 100 μg ml^{-1} antigen and 20% (v/v) of a supernatant from Con A-stimulated spleen cells prepared as described by Rosenberg *et al.*[18]. The clones were expanded in these conditions for 2–3 weeks. Cultures were fed every 3 d by removing 50–70 μl of medium and replacing it with 100 μl of fresh medium containing antigen, irradiated spleen cells and Con A supernatant. After suitable expansion aliquots of the clones were examined for reactivity in a standard 6-d proliferation assay[14,17] using ^{3}H-thymidine incorporation (1 to 2×10^3 cells) with supplemental feeding at 3 d or by recloning (200 cells) as described in Table 1 immediately after feeding. The experiments shown were carried out with cells derived from a single clone of B10.A T cells selected for DNP-OVA reactivity or a single clone of B10 T cells selected for GAT reactivity. DNP-poly(Glu^{60}Lys^{40})(DNP-GL) and DNP-poly(Glu^{42}Lys^{28}Ala^{30}) (DNP-GLA) were gifts from Dr Charles Janeway, Department of Pathology, Yale University Medical School. The values for thymidine incorporation represent the mean of three separate experiments, the values for recloning the mean of two separate experiments. ND, not determined.

* Means ± s.e.m.

result obtained when both GAT (21 colonies alone) and PPD (32 colonies alone) were used together (52 colonies). Similar numbers of colonies were obtained from mice bearing different (MHC) haplotypes when antigens to which all strains respond, such as PPD and DNP-OVA, were used. In contrast, strains known to be low responders to particular antigens[14] yielded only a few colonies. For example, C57BL/10 (B10) is a high responder to GAT, whereas B10.S is a low responder. As shown in Table 1, the clonal frequency for GAT of B10 lymph node cells was 1.1×10^{-5} and that for B10.S was only 1×10^{-6}, yet these same two strains gave almost identical clonal frequencies for PPD. The F$_1$ hybrid between these two strains (B10.S×B10) behaved like the high responder with a clonal frequency of 1×10^{-5} (Table 1). These results correlate perfectly with the antibody[15] and T lymphocyte proliferative[14] responses to GAT found in these strains and suggest that the MHC-linked immune response (*Ir*) genes that control the magnitude of those responses also control the differences in clonal frequency.

Colonies were picked and the cells expanded in liquid culture. Cell growth required antigen, fresh antigen-presenting cells in the form of irradiated spleen cells, and growth factors from 48 h supernatants of concanavalin A (Con A)-stimulated spleen cells (Table 2 legend). More rapid expansion could be achieved if free Con A was also added; however, this was not essential. When the cells had increased in number to 10^5, individual clones were chosen to study antigen specificity. Specificity was examined by thymidine incorporation and by recloning. As shown in Table 2, a colony originally selected for responsiveness to GAT could only be restimulated by GAT. One thousand cells incorporated enough ^{3}H-thymidine to give 7,900 c.p.m. whereas the same number of cells stimulated with DNP-OVA or PPD yielded background radioactivity levels. Similarly, only GAT stimulation yielded significant numbers of colonies on recloning, 66 colonies from 100 cells plated for a clonal frequency of 6.6×10^{-1}. On the other hand a colony originally selected for responsiveness to DNP-OVA could not be stimulated by GAT or

Table 3 Control of antigen presentation by genes in the I–A subregion of the MHC

Spleen cells Strain	Spleen cells MHC*	Presence of antigen	T-lymphocyte clones (source and specificity) B10.A: specific for DNP-OVA	T-lymphocyte clones (source and specificity) B10: specific for GAT

Irradiated nonimmune spleen cells from various H-2 congeneic mouse strains were tested in a 6-d proliferation assay for their ability to present antigen to 2×10^3 DNP-OVA-specific, cloned B10.A T cells or 2×10^3 GAT-specific, cloned B10 T cells. 100 μg ml^{-1} DNP-OVA was used to stimulate the B10.A clone and 100 μg ml^{-1} GAT was used to stimulate the B10 clone. The conditions were the same as those described in Table 2. The values shown are from one of four such experiments. The standard errors of the mean were calculated from triplicate determinations for each value.

*The letters refer to the haplotype source of origin of the K, I-A, I-B, I-J, I-E, I-C, S, G and D regions of the murine major histocompatibility complex (MHC).

PPD. It could be stimulated by DNP-OVA, TNP-OVA and OVA although not by the hapten on different carriers DNP-poly($Glu^{60}Lys^{40}$) and DNP-poly($Glu^{42}Lys^{28}Ala^{30}$), nor trinitrophenyl-keyhole limpet haemocyanin (TNP-KLH). The original carrier alone, OVA, was not as potent a stimulator as DNP-OVA although at high concentrations (300 $\mu g\, ml^{-1}$) it could stimulate as many colonies as the immunogen. This difference is reflected in the complete dose–response curve (data not shown) suggesting that the T-cell receptor has a slightly higher affinity for DNP-OVA than for OVA. These results indicate that the receptor is not uniquely specific for a new antigenic determinant created by the hapten-carrier conjugation but rather that the receptor recognises predominantly a carrier determinant which has been modified by the hapten.

The recloning frequency was also dependent on the concentration of OVA used. At 100 $\mu g\, ml^{-1}$, the clonal frequency was 35 per 100 cells plated (3.5×10^{-1}) whereas at 300 $\mu g\, ml^{-1}$ it reached 80–85 per 100 (8.5×10^{-1}), a level comparable to that achieved with DNP-OVA. These high recloning frequencies represent an enrichment in specific cells of 70,000-fold relative to the clonal frequency obtained with the cells freshly removed from the animal (compare Tables 1 and 2). This result strongly suggests that our single step technique has produced true T-cell clones, and that the recloning frequencies actually represent the highest attainable cloning efficiencies of the method. To prove that the colonies were really derived from a single cell, 14 of the recloned DNP-OVA colonies were expanded and tested for antigen specificity. All of them showed a pattern of responsiveness identical to that shown in Table 2 for the original DNP-OVA colony. As all the progeny are identical it is reasonable to assume that they have been derived from a single homogeneous population, that is, that the original colony was a true clone.

The requirement for fresh irradiated spleen cells to expand the clones in liquid culture suggested antigen-presenting cells were necessary to effectively stimulate the T lymphocytes. Previous studies[16] from this laboratory have demonstrated that the genes encoded in the I-A subregion of the MHC control such T lymphocyte antigen-presenting cell interactions. Table 3 shows that the same restrictions apply to the clones. A GAT-specific clone isolated from a B10 mouse and a DNP-OVA-specific clone isolated from a B10.A mouse were stimulated with their respective antigens in the presence of irradiated spleen cells from either B10 or B10.A mice or mice bearing recombinant chromosomes in the MHC. In the absence of antigen no stimulation was observed (Table 3), even if syngeneic and allogeneic spleen cells were added together or F_1 spleen cells were used (data not shown). This absence of a mixed lymphocyte reaction indicates that these two particular clones do not possess alloreceptors for B10 or B10.A MHC gene products. In the presence of antigen only spleen cells histocompatible at the I-A subregion supported a proliferative response. Thus, the DNP-OVA-specific B10.A clone was stimulated by antigen in the presence of B10.A, B10.A(4R) and A.TL spleen cells but not B10 or B10.A(5R) spleen cells. For the GAT-specific B10 clone the results were just the opposite (Table 3). These genetic results are identical to what we have previously reported for whole T-cell populations[16]. They demonstrate that the phenomenon of MHC restriction is not the result of suppression by cells other than the responding cells, but rather a failure of individual clones to respond to the antigen unless it is presented in association with the appropriate MHC products.

The method we have described provides a rapid and direct technique for the generation and expansion of antigen-specific T-lymphocyte clones. Several of these clones have been maintained in culture for 4 months without loss of specificity. The power of this method is the ability to obtain directly from the animal pure populations of cells which are present in relatively low frequency(for example, for GAT the precursor frequency = clonal frequency ÷ plating efficiency = 3 per 10^5, assuming that the recloning frequency represents the plating efficiency). Thus, any problems of *in vitro* selection inherent in the techniques of cloning long-term lymphoblast cell lines[11-13] are avoided. These clones should prove useful for the biochemical analysis of T-lymphocyte function, for the purification and characterisation of T-lymphocyte receptors and for the study of the mechanism of MHC restriction and the action of *Ir* genes.

A monoclonal antibody to human acute lymphoblastic leukaemia antigen

Jerome Ritz, John M. Pesando, Jean Notis-McConarty, Herbert Lazarus & Stuart F. Schlossman

Division of Tumor Immunology, Sidney Farber Cancer
Institute, Harvard Medical School, Boston, Massachusetts 02115

Previous studies by Greaves[1] and others[2–6] have demonstrated the existence of an antigen associated with cells from many patients with acute lymphoblastic leukaemia (ALL) and some patients with chronic myelocytic leukaemia (CML) in blast crisis. Antisera to this common ALL antigen (CALLA) have been produced in rabbits and require extensive absorption which limits both the titre and quantity of antisera that can be generated and may result in variable specificity in different laboratories. The method for generation of specific antibody by somatic cell hybridisation introduced by Kohler and Milstein[7] has been successfully used to produce monoclonal antibodies against various normal human cell-surface proteins, including β_2 microglobulin[8], histocompatibility antigens[9], thymocyte and peripheral T-cell antigens[10–12] and Ia-like antigens[13]. The present report describes the generation and characterisation of a monoclonal antibody specific for a common ALL antigen (CALLA) previously identified by conventional heteroantisera.

Our cell fusion procedure was derived from the method developed by Kohler and Milstein[14] with several modifications described by Kennett *et al.*[15]. The MOPC-21 variant, P3/NS1/1-Ag4-1, was used as the parent myeloma cell line. Spleen cells were obtained from two BALB/c mice which had each been immunised by intraperitoneal and subcutaneous injections of 2×10^7 ALL cells emulsified in complete Freund's adjuvant. One and five weeks later, an additional 1×10^7 leukaemic cells were injected intravenously. Four days after the last injection, 2.2×10^8 spleen cells were collected and fused with 6×10^7 myeloma cells in the presence of 30% polyethylene glycol and aliquoted into seven microtitre plates (Falcon). Aminopterin was added 24 h after fusion and macroscopic hybridoma colonies became evident between 10 and 28 d in culture.

Rabbit antiserum to CALLA was generated in our laboratory[16] by immunisation with either ALL cells or the Null-ALL cell line Laz 221 (ref. 17), followed by absorption with cells from an autologous B-lymphoblastoid cell line and the leukaemic T-cell line, CEM[18]. The initial screening of hybridoma supernatants also used these cell lines, which provided large homogeneous populations of cells that had been extensively characterised with conventional heteroantisera. All cell surface characterisation was done by standard indirect immunofluorescence assay with subsequent analysis of each population by the fluorescence activated cell sorter (FACS-I) (Becton, Dickinson).

Although mice were immunised with cryopreserved ALL cells from a single patient known to be CALLA positive, hybridoma supernatants were initially screened for reactivity to the Null-ALL cell line Laz 221 to select against antibodies to clonotypic antigens. Only supernatants reactive with Laz 221 underwent further analysis with Laz 388 (a B-lymphoblastoid cell line from the same individual as Laz 221) and CEM, thereby approximating the absorptive method for production of rabbit anti-CALLA. Hybridomas reactive with Laz 221 but unreactive with Laz 388 and CEM demonstrated 'CALLA-like' specificity and were then subcultured and injected into pristane-primed BALB/c mice to produce immune ascites[15]. These ascites were then screened for reactivity against a large panel of cryopreserved leukaemic cells which had been previously phenotyped with rabbit anti-CALLA. Twenty-two different hybridoma supernatants demonstrated CALLA-like reactivity with Laz 221, Laz 388 and CEM, but only one clone had specificity for CALLA when tested with this panel of leukaemic cells. All other clones were reactive with cells from some patients with AML-, CLL-, or CALLA-negative ALL. Table 1 summarises the pattern of reactivity observed with a single hybridoma, J-5, compared with rabbit anti-CALLA. In all 70 populations, reactivity was similar to that of rabbit anti-CALLA demonstrating specificity for leukaemic cells from most patients with non-T-cell ALL and some patients with CML in blast crisis. In addition, no J-5 reactivity was detected with cells from five T-ALL cell lines (CEM, HSB-2, Laz 191, HJD-1 and HHM-1).

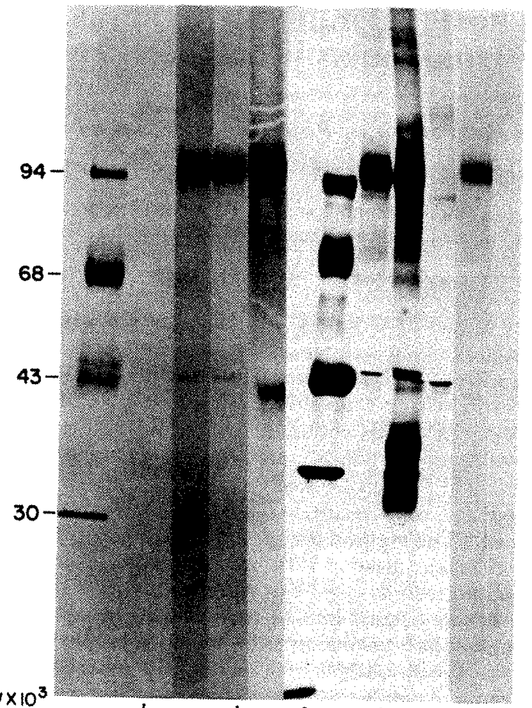

Fig. 1 Immune precipitation experiments with J-5 and rabbit anti-CALLA. *a*, ^{14}C-labelled MW standards (NEN); *b*, control monoclonal ascites with Laz 221; *c*, J-5 ascites with Laz 221; *d*, J-5 with cells from a CALLA-positive patient; *e*, J-5 with NALM-1; *f*, ^{14}C-labelled MW standards; *g*, rabbit anti-CALLA with Laz 221; *h*, rabbit anti-ALL serum absorbed only with CEM cells; *i*, normal rabbit serum with Laz 221; *j*, rabbit anti-CALLA with cells from a CALLA-positive patient. Cells were labelled with ^{35}S-methionine (NEN) for 16 h at 37 °C. Nonidet-P40-solubilised membrane extracts were applied to a lentil lectin column and bound glycoproteins eluted with 3% α-methyl-D-mannoside. Peak tubes were pooled and divided equally among samples containing antibody bound to Protein A-Sepharose (Pharmacia). After overnight incubations at 4 °C, samples were washed, heated for 5 min at 110 °C and applied to a large 7–20% gradient polyacrylamide slab gel for electrophoresis at 150 V for 18 h. Autoradiographs of dried gels were obtained by exposure for 7 d at −70 °C.

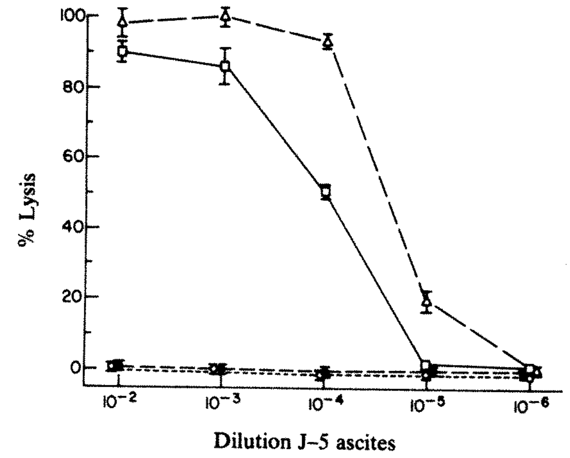

Fig. 2 Specificity of monoclonal J-5 antibody was tested using complement-mediated lysis of ^{51}Cr-labelled target cells. 4×10^3 radiolabelled target cells (20 μl) were incubated with various dilutions of J-5 ascites (20 μl) at 20 °C for 60 min followed by addition of rabbit complement (20 μl, 1:5 dilution) and further incubation at 37 °C for 60 min. Cell lysis was detected by release of ^{51}Cr into cell supernatants. All assays were done in triplicate and per cent lysis was calculated as follows: % lysis = [(experimental − spontaneous release)/(freeze-thaw − spontaneous release)] × 100. □, Laz 221; △, NALM-1; ●, Laz 388; ○, CEM.

Previous studies in several laboratories have demonstrated that heteroantisera with CALLA specificity identify a single glycoprotein with a molecular weight (MW) of 95–100,000 present on some ALL cells and the cell line NALM-1 derived from a patient with CML in blast crisis[4,19]. Figure 1 demonstrates that immune precipitates with both clone J-5 and rabbit anti-CALLA identify a single 95,000-MW glycoprotein band on cell membranes from Laz 221, NALM-1 and a CALLA-positive patient with ALL, confirming that the two antisera have similar specificity.

Specific reactivity of clone J-5 ascites was also tested by microcytotoxicity assay measuring release of ^{51}Cr from labelled target cells (Fig. 2). Greater than 50% lysis was observed with ascites dilutions of 10^{-4} on the positive cell lines Laz 221 and NALM-1, but no lysis was noted at any dilution on the negative cell lines Laz 388 and CEM. In experiments designed to test the limits of specificity and effective cytotoxicity of J-5, constant numbers of ^{51}Cr-labelled Laz 221 cells were mixed with unlabelled autologous cells (Laz 388) before addition of immune ascites (Fig. 3). Significant cytoxicity was demonstrated after a single treatment with J-5 ascites (1:1,000 dilution), when positive cells represented only 0.1% of the population mixture.

Various haematopoietic cells have also been screened for reactivity with J-5 ascites to determine whether this antibody might be identifying an antigen present on normal cells. No J-5 reactivity was demonstrated with normal peripheral blood mononuclear cells, purified T or B cells, concanavalin A-activated T cells, monocytes or spleen lymphocytes. Whereas Greaves[20] and Janossy *et al.*[21] have reported that CALLA-positive cells are present in fetal and regenerating bone marrow, we have been unable to demonstrate similar reactivity with

Table 1 Reactivity of hybridoma J-5 with leukaemic cells compared to rabbit anti-CALLA

Patients	Rabbit anti-CALLA	Hybridoma J-5
Non-T-cell ALL	21/34*	21/34
T-cell ALL	0/8	0/8
CLL	2/10†	0/10
AML	0/10	0/10
CML-blast crisis	3/5	3/5
CML-stable phase	0/3	0/3

All analyses were carried out on cryopreserved leukaemic cells obtained before the start of chemotherapy, using a standard indirect immunofluoresence assay. 10^6 cells were incubated for 30 min at 4 °C with either 0.1 ml J-5 ascites or negative control ascites (1:100 dilution to ensure antibody excess), washed twice, incubated for an additional 30 min at 4 °C with 0.1 ml fluorescein-conjugated goat anti-mouse IgG (Meloy, 1:40 dilution), and washed three times before analysis. Intensity of fluorescence with J-5 was determined for 40,000 cells in each population by the FACS-I and compared with fluorescence with negative control ascites. Any reactivity with monoclonal antibody above background was considered positive. Analysis with rabbit anti-CALLA was similar except that antisera were used at a 1:20 dilution and $F(ab')_2$ fluoresceinated goat anti-rabbit $F(ab')_2$ was used as a developing reagent.

* Each fraction represents the number of positive populations over the total number tested. Except as described below (†), leukaemic cells were either positive or negative with both rabbit anti-CALLA and hybridoma J-5. Intensity of fluorescence of positive populations, however, was not always identical and cells from three patients exhibited strong fluorescence with rabbit anti-CALLA but only weak reactivity with monoclonal J-5.

† Cells from two CLL patients were initially weakly positive with rabbit anti-CALLA but subsequent cross-absorption experiments[16] demonstrated that this reactivity was not specific for CALLA. Monoclonal J-5 antibody confirms this finding.

monoclonal J-5 antibody using both the FACS-1 and fluorescence microscopy. Eight bone marrow samples have been analysed including normal adult marrow (two volunteers) and regenerating marrow after either chemotherapy (four patients) or bone marrow transplantation (two patients). In addition, there was no detectable reactivity with J-5 ascites and 18-week fetal liver, bone marrow or thymus. This lack of reactivity with regenerating bone marrow and fetal haematopoietic tissues suggests that J-5 antibody is detecting a unique antigen which may be leukaemia specific.

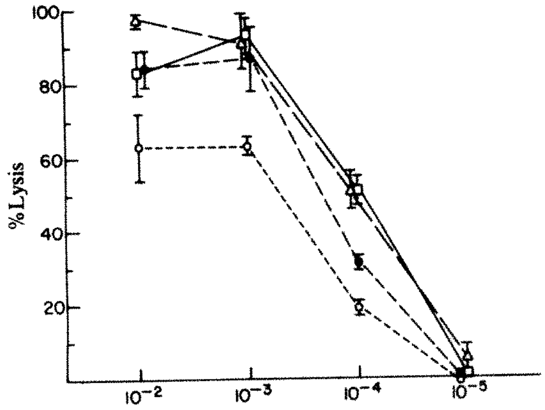

Fig. 3 Effective cytotoxicity of monoclonal J-5 was tested by mixing 10^3 ^{51}Cr-labelled Laz 221 cells with 10^4, 10^5 or 10^6 unlabelled Laz 388 cells before addition of ascites at various dilutions. Cells (100 µl) were incubated with ascites (100 µl) at 20 °C for 60 min followed by addition of rabbit complement (100 µl, 1:5 dilution) and additional incubation at 37 °C for 60 min. All assays were carried out in triplicate and per cent lysis calculated as described in Fig. 2 legend. □, 100% Laz 221; △, 10% Laz 221; ●, 1% Laz 221; ○, 0.1% Laz 221.

These studies demonstrate that J-5 monoclonal antibody will be a valuable diagnostic and therapeutic reagent. The extensive absorption required to make conventional heteroantisera specific for ALL cells and the relatively weak lytic capacity of these reagents have limited their clinical application. Development of a monoclonal antibody with CALLA specificity overcomes these obstacles and will allow clinical trials of *in vitro* and *in vivo* specific immunotherapy.

We thank H. Levine for technical assistance and Dr P. Stashenko for donating the NS1 cell line used in these experiments. This work was supported by NIH grants AI 12069, CA 19589 and CA 06516 and fellowship CA 06270. J.M.P. is a recipient of a fellowship from the Cancer Research Institute.

The appearance of single-ion channels in unmodified lipid bilayer membranes at the phase transition temperature

V. F. Antonov, V. V. Petrov, A. A. Molnar, D. A. Predvoditelev & A. S. Ivanov

Research Centre, 2nd Medical Institute, Ostrovitjanova 1,
117437 Moscow, USSR

Ion-specific channels in artificial membranes have been formed by the addition of gramicidin A[1], alamethicin[2], polyene antibiotics[3] and some proteins[4] to the solution surrounding the bilayer lipid membrane. Until now there have been no reports of single-ion channels in unmodified lipid membranes. We have now studied the electrical conductance of planar lipid bilayers membranes made of synthetic distearoylphosphorylcholine (DSPC). Current fluctuations of amplitude ~1pA and duration ~1 s have been discovered at phase transition temperature, which shows that the appearance of ionic channels may be the result of lipid domain interactions. This would explain the dramatic increase in ion permeability observed in liposomes during phase transition. We suggest that these channels could conduct the transmembrane ionic current in biological membranes without the involvement of peptides and proteins.

The ionic permeability is known to change in the black lipid membrane formed from DSPC at the phase transition[5], since there is a jump in membrane conductance at 59°C, the phase transition temperature of DSPC. As the change of the integral conductance at this temperature was sharp and reversible, it was suggested that there might be a single-ion channel in the bilayer lipid membrane at this temperature.

0028-0836/80/060585—02$01.00

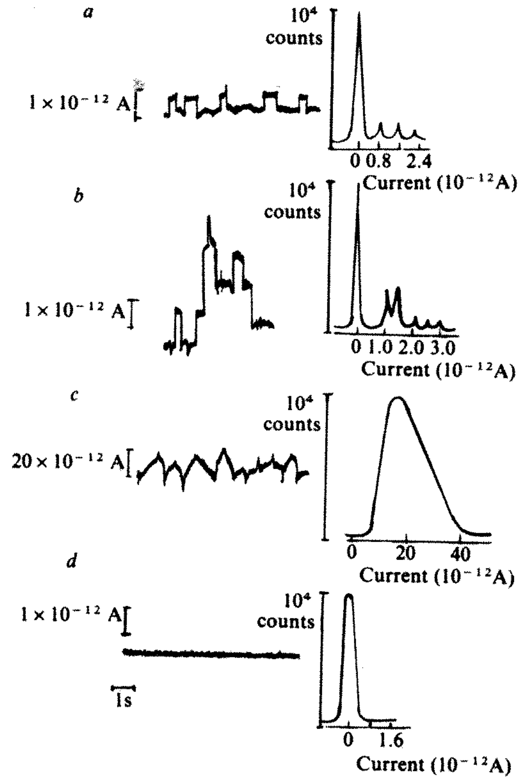

Fig. 1 Left, groups of fluctuations in the current through a lipid bilayer membrane. Right, occurrence of corresponding frequencies of the open channels, recorded by NTA-1024 multichannel analyser. The frequency was obtained by sampling the current at 200-μs intervals. [Applied potential, 100 mV.] *a*, Bilayer lipid membranes were formed from 0.2% DSPC at 59±0.2 °C. The bathing medium contained 1M KCl, 0.003M Tris-HCl *p*H 7, 4. *b*, Bilayer membranes formed from egg lecithin in *n*-decane at 22 °C. Gramicidin A 10^{-9} M was added. Egg lecithin was obtained by the method of Folch *et al.*[12]. *c*, Bilayer membranes formed from DSPC in *n*-decane at a temperature below 59 °C. *d*, Bilayer membranes formed from DSPC in *n*-decane at a temperature above 59 °C.

In an attempt to demonstrate this single-ion channel, transmembrane currents were measured in voltage-clamp conditions. The amplitude analysis of the current pulses was produced by multichannel analyser NTA-1024.

The lipid bilayer membranes were formed at holes in a Teflon 'wall' according to Mueller *et al.*[6] The temperature in the cell was kept constant by a thermostat, and the temperature around the membrane was measured by thermocouple. The DSPC used in this study was synthesised in our laboratory and contained no impurities that could be detected by thin-layer chromatography and other methods[7]. Gramicidin A (Calbiochem) was used without additional purification.

The experiments demonstrated transmembrane current fluctuation when the temperature in the cuvette was near the phase transition temperature of DSPC (Fig. 1*a*, left). The histogram reveals the discrete character of the current impulses distribution (Fig. 1*a*, right). The current fluctuation amplitude ranges discretely from 0.8 to 2.4 pA. Note that if the temperature rises above 59 °C, there are no transmembrane current fluctuations and, simultaneously, the integral membrane conductivity falls to 10^{-8} S cm^{-2}. If a noise with amplitude much higher than that of a separate current fluctuation appears, the temperature is well below the phase transition temperature (Fig. 1*c*). The integral conductance of the membrane increases sharply at this temperature. Note that these current changes are completely reversible and may repeat themselves in successive cycles of high and low temperature.

It should also be noted that the appearance of single current fluctuations (Fig. 1*a*, left) was observed in every experiment, but because of technical difficulties, it was not possible in every experiment to record sufficient fluctuations for statistical treatment (Fig. 1*a*, right) (for example, 100 single fluctuations were observed only in 10% of the experiments).

Compared to published data, it is evident that the characteristics of the current fluctuations at the phase transition are very different from those which are obtained by alamethicin[2] and EIM[4] on lipid membranes; but life times and amplitudes of the channels formed by gramicidin A in the black lipid membrane are similar (compare Fig. 1*a* and *b*).

Interestingly, the distribution of current fluctuations at the transition temperature of DSPC depends strongly on the length of time that membranes are at the fixed temperature.

The transmembrane current fluctuations reported here are evidence of the appearance of ion channels in non-modified bilayer membranes and prove that the observed ionic channels at the transition temperatures of DSPC are connected with phase transition. We assume that the ion channels appear when lipid domains interact in the membranes.

One possibility that must be considered is the involvement of impurities[10] in channel formation. This seems unlikely for the following reasons. If the channel appearance were due to impurities, we would expect a decrease in integral conductance, infrequent current fluctuation, and displacement of histogram peaks to low-amplitude values, because after repeated temperature transitions the accumulation of impurities at the phase transition should be associated with a release of some impurities into the water solvent. Therefore the content of impurities would be considerably decreased in the lipid bilayer after several repetitions of the cycle. This suggestion is based on the well known effect of zonal rectification of metals from impurities. Published data supporting this approach prove that the constant of distribution of impurities between gel and liquid crystalline phases is rather low (0.029 for dipalmitoyllecithin[8]). However, experimental data showed that neither current fluctuations nor the histogram were changed by repeated phase transitions. The integral conductance scatter is not more than 30%.

During studies of the ionic selectivity of channels we synthesised a positively charged analogue of DSPC containing a P-CH_3 group instead of P-OH group[9]. We suppose that channel walls are formed from polar groups of phospholipids. Neutral DSPC forms channels which show no ionic selectivity, whereas a positively charged analogue induces anion selectivity. This result supports the conclusion that the main phospholipids, and not impurities, are responsible for the ionic channel formation, because the synthesis schemes for the two phospholipids are the same, so the two lipid bilayers should contain identical impurities.

In bilayer membranes formed from a mixture of DSPC with 1 mol % of other synthetic lipids or egg lecithin, at the transition temperature only the DSPC-channels were recorded (data not shown). Thus lipids such as egg lecithin which constitute an impurity do not influence the formation of ionic channels at the phase transition temperature of DSPC. The suggestion impurities do not influence the formation of ionic channels is further supported by data obtained by several authors[10,11] in studies of ionic selectivity of synthetic phospholipid liposomes at the phase transition.

Light- and GTP-regulated interaction of GTPase and other proteins with bovine photoreceptor membranes

Hermann Kühn

Institut für Neurobiologie der Kernforschungsanlage Jülich,
D-5170 Jülich, Postfach 1913, FRG

Light absorption by photoreceptor rod outer segments (ROS) leads not only to spectral and structural changes in the rhodopsin molecule[1] but also to the activation of several enzymatic activities[2–6] including GTPase[7–10]. The mechanism of this effect is not known; however, in all cases where the action spectrum of light-induced enzyme activation has been measured (see, for example, refs 4, 8), it matched the absorption spectrum of rhodopsin. This suggests that bleaching of rhodopsin is the primary step in enzyme activation, and that some light-induced changes in the molecular interaction of the enzymes with rhodopsin, the major intrinsic ROS membrane protein, should be involved. I have indeed found that light induces profound changes in the interaction of rhodopsin kinase[11], GTPase (reported here), and other proteins with the photoreceptor membrane. These changes are reversible in the dark, are strongly influenced by GTP, and are thought to be involved in the regulation of enzyme activity by light. The light-induced binding of the GTPase and its subsequent elution with GTP was used to purify this enzyme.

Bovine ROSs were purified from freshly dissected retinas by flotation and subsequent centrifugation on stepwise sucrose density gradients in 70 mM phosphate buffer[11]. Electron microscopy[12] revealed large fragments of ROS, 2–20 µm long, surrounded by a plasma membrane which looked continuous. There was no detectable contamination by other cell fragments. The ratio A_{280}/A_{500} of the ROS was 2.0–2.4, indicating good purity[13].

Gel electrophoresis of such purified ROSs (Fig. 1*a*, *b*) shows that rhodopsin is the major protein but that a number of additional polypeptides is also present, in agreement with published data[14]. Most of these additional polypeptides are soluble in the dark in hypotonic buffer (Fig. 1*d*); little protein besides rhodopsin remains with the washed membranes (Fig. 1*c*). The major four polypeptides present in dark extracts (doublet bands at molecular weights (MWs) 37,000 and 35,000 and at about 95,000) are extractable at low ionic strength but are barely extractable at moderate ionic strength (70 mM phosphate buffer[11], 100 mM Tris buffer, or 120 mM KCl Ringer's); this suggests that they are peripherally bound membrane proteins. Most of the other polypeptides can be extracted at moderate ionic strength, provided the ROS plasma membrane is disrupted, and may therefore be cytoplasmic soluble proteins or only very weakly bound membrane proteins[11].

Illumination of the ROS suspension before centrifugation causes certain polypeptides to disappear almost completely from the soluble supernatant (Fig. 1*e*; MWs 35,000, 37,000, 48,000 and 68,000, and a peptide of MW about 6,000 discernible in the front band near the bottom of the gels). These polypeptides become membrane-bound upon illumination and sediment with the bleached membranes. They are found in the membranous pellet (not shown in Fig. 1) and can be eluted from the pellet by subsequent treatments which is demonstrated, for example, in Fig. 1*o*, *p* for the polypeptides of MWs 37,000, 35,000 and 6,000. The light-induced binding to the bleached membranes is slowly reversed in the dark: If ROS suspensions are bleached but then further incubated in the dark for 70 min at 20 °C, then most of the initially bound polypeptides are found again in the soluble supernatant after centrifugation (Fig. 1*g*).

This light-induced and reversible binding has been observed previously[11] for the two polypeptides (MWs 68,000 and 48,000) which are soluble at moderate ionic strength, and the polypeptide of MW 68,000 has been identified as rhodopsin kinase. To demonstrate that the three additional polypeptides (MWs 37,000, 35,000 and 6,000) undergo light-induced changes in their interaction with the membrane, it is necessary to subject the membrane to conditions of low ionic strength. Then, light–dark differences in the binding affinity of these peripheral membrane proteins to the membrane become obvious. The binding is too weak in the dark to withstand the low ionic strength treatment; in light, however, the binding becomes much stronger, such that it resists the low ionic strength treatment for a limited time after bleaching.

Table 1 GTPase activities of the preparations shown in Fig. 1

Gel (Fig. 1)	Preparation	GTPase activity*
a	Purified ROS before extraction, 2.4 µg rhodopsin	6.0
b	As *a*, but 12 µg rhodopsin	28.8
c	Extensively washed ROS membranes, 12 µg rhodopsin	0.36
d	Dark extract, obtained from unbleached ROS (corresponding to 35 µg rhodopsin) in 5 mM Tris	41.4
e	Light extract from ROS (35 µg) bleached for 3 min, centrifuged immediately after bleaching	0.9
f	Extract from bleached ROS, centrifuged after a 2-min dark incubation period at 20 °C following bleaching	1.7
g	Extract from bleached ROS, centrifuged after a 70-min dark incubation period following bleaching	27.1
d'	Dark extract *d* assayed without addition of washed ROS	0.43
	Effect of GTP on the light-induced binding	
h	Dark extract obtained from unbleached ROS in the presence of 1 mM GTP	—
i	Light extract from ROS bleached in presence of GTP and centrifuged immediately after bleaching	—
k	Extract from ROS bleached in absence of GTP and then dark-incubated for 2 min after adding GTP	—
l	Extract from ROS bleached in absence of GTP and then dark-incubated for 70 min after adding GTP	—
	Purification of the GTPase via light-induced binding	
m	Extract obtained in a second wash of a bleached ROS pellet with 5 mM Tris	1.2
n	Further extraction of the bleached pellet by prolonged incubation with 100 mM Tris at 20 °C	0.22
o	Purified GTPase (2.8 µg protein) obtained by extracting the thoroughly washed bleached pellet with 40 µM GTP	38.0
p	Purified GTPase as *o*, but 13.8 µg protein	—

The preparations and amounts of protein used for the GTPase assays were the same as for the correspondingly lettered gels in Fig. 1. For details of the extraction procedure in darkness and light see legend to Fig. 1. The GTPase activity values given are averages of four determinations with s.d. < 5%. Assays were performed according to the method of Neufeld and Levy[20] with some modifications[8,15]. Incubation was for 2–8 min at 30 °C in continuous light. The assay mixture contained 2 µM [γ-^{32}P]GTP (except sample *o*, 3 µM ^{32}P-labelled GTP) of specific activity 2,200–3,000 c.p.m. pmol^{-1}; 20 mM Tris-HCl (*p*H 7.4); 5 mM $MgCl_2$; 1 mM dithiothreitol; and the appropriate amounts of ROS and/or extracts, in a final volume of 200 µl. To each assay of extracts (*d*–*g*, and *m*–*o*), 4.7 µg rhodopsin in the form of washed, GTPase-depleted ROS membranes was added for activation of the extracted GTPase. When GTPase-containing extracts were assayed in the absence of rhodopsin, they showed no GTPase activity (sample *d'*).

* GTPase activity is expressed as pmol P_i liberated per min at 30 °C per amount of protein seen on the gels of Fig. 1.

One of the most striking features of this light-dependent protein binding is that GTP (10^{-5}–10^{-3} M) inhibits, or reverses, the light-induced binding of the polypeptides MWs 37,000, 35,000 and 6,000 if it is present during bleaching (Fig. 1*i*) or added shortly after bleaching (Fig. 1*k*, *l*). In the dark, GTP has little influence on the extractability in hypotonic buffer (Fig. 1*h*). This solubilising effect is relatively specific for GTP—other nucleotides had only a partial effect (ATP, guanylyl imidodiphosphate) or no effect (3',5'-cyclic GMP, 5'-GMP, and others)[15]. GTP also affects the solubility of the polypeptide of MW 48,000, but in an opposite way: The light-induced binding of this polypeptide, which is normally reversible in the dark (Fig. 1*g*), becomes irreversible if GTP is present (Fig. 1*l*).

0028–0836/80/060587—03$01.00

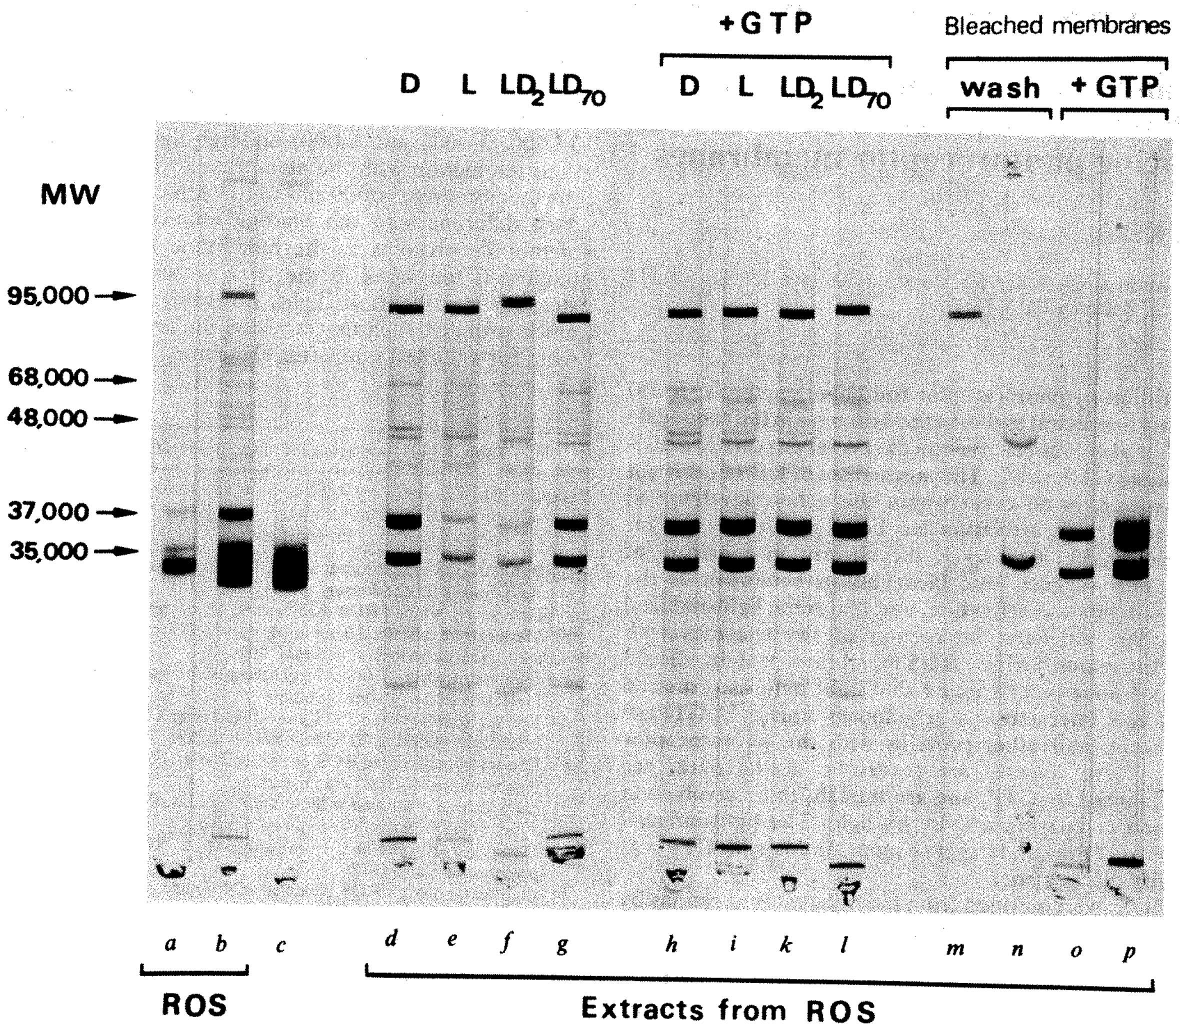

Fig. 1 Polypeptide composition of ROS and extracts, analysed by electrophoresis on discontinuous, 10% polyacrylamide gels in the presence of 0.1% SDS[17]. Gels were stained for protein with Coomassie brilliant blue. For definition of the lettered samples see Table 1, where the corresponding GTPase activities are also listed. Briefly: gels *a–c* represent ROS membranes before (*a*, *b*) and after (*c*) extraction of soluble proteins; and gels *d–p* represent soluble proteins extracted from ROS in various light/dark conditions. The extracts *d–l* were all obtained from the same ROS suspension in 5 mM Tris-HCl (*p*H 7.4): 2 mM dithiothreitol: 0.5 mM $MgCl_2$: 0.05 mM phenylmethylsulphonyl fluoride. The amount of extract on each gel (*d–l*) corresponds to 35 μg rhodopsin in the original homogenised ROS suspension. The ROSs were extracted either unbleached (*d*, *h*) or after illumination (*e–g*, *i*, *k*, *l*). The 'light' suspensions were illuminated for 3 min at 20 °C with light filtered through an orange filter ($\lambda > 540$ nm) and through a water bath, bleaching about 80% of the rhodopsin. Then both light and dark suspensions were centrifuged either immediately (*d*, *e*, *h*, *i*) or after an additional incubation period at 20 °C in the dark (*f*, *g*, *k*, *l*). (The light/dark conditions applied before centrifugation are depicted on top of the gels: D, dark extract; L, light extract; LD_2 and LD_{70}, dark incubation for 2 min or 70 min, respectively, following illumination.) The extracts *h–l* were obtained in the presence of 1 mM GTP. For details see Table 1. After the first centrifugation (10 min at 50,000*g* and 0 °C), the supernatants were carefully removed and centrifuged again for 40 min at the same speed to insure that all particulate material was sedimented. The extracts were clear and free of rhodopsin. The GTPase was purified as follows: An ROS suspension was bleached and centrifuged. The bleached pellet containing the bound GTPase was washed several times with 5 mM Tris at 0° C to remove residual soluble proteins (*m*) and was then treated several times with 100 mM Tris for 70 min at 20 °C to allow for the release of light-induced bound proteins (*n*) other than GTPase. The GTPase remains membrane-bound in 100 mM Tris. The GTPase was finally eluted by treating the pellet with 40 μM GTP in 5 mM Tris buffer (*o*, *p*). All buffers used contained 2 mM dithiothreitol. MWs of polypeptides are indicated on the left side of the gels and were estimated from gels run separately in a continuous electrophoretic system[15,18]. The most prominent band in ROS, migrating on Laemmli gels[17] below the extractable polypeptide of MW 35,000, is rhodopsin, as identified by glycoprotein staining (not shown). Polypeptides whose MWs are less than 20,000 migrate with the front on these gels[17]. This front band contains a light-dependent component which is seen in the extracts *d* and *g–l*, and in the purified GTPase (*o*, *p*) but is absent in the light extracts *e* and *f*. Analysis in a gel electrophoretic system designed to separate in the MW range of 2,000–20,000 (ref. 19) indicates a MW of about 6,000 for this light-dependent peptide. It always accompanies the GTPase and is, therefore, tentatively regarded as a subunit of the GTPase in addition to the polypeptides of MWs 37,000 and 35,000. The polypeptide of MW 68,000 carries rhodopsin kinase activity[11]. The polypeptide doublet of MW 95,000, in contrast to the other designated polypeptides, is extracted independently of light.

GTPase activities of the different fractions from Fig. 1 are presented in Table 1. Whole ROS, if assayed in the conditions described by Wheeler and Bitensky[8], exhibit GTPase activities in the same range as those reported for frog ROS in light[8]. Dark extracted and thoroughly washed ROS membranes (Fig. 1*c*) contain no GTPase activity (Table 1*c*). The extracts also show negligible GTPase activity (Table 1*d′*), unless assayed in the presence of added, GTPase-depleted bleached ROS membranes. Then the dark extracts show high GTPase activities, up to 40 times higher than the corresponding light extracts (Table 1*d*, *e*). Obviously, the GTPase is extracted from dark-adapted membranes in an inactive form and becomes active only when bleached ROS membranes are added. Extracts of bleached ROS, on the other hand, contain little GTPase because of the light-induced, strong binding of the enzyme to the membranes; but after prolonged incubation in the dark, the strongly bound GTPase is reconverted into the form where it can be extracted at low ionic strength (Table 1*g*). Comparison of GTPase activities and polypeptide composition of many extracts showed that the presence of the three light- and GTP-influenced polypeptides (MWs 37,000, 35,000 and about 6,000) always and quantitatively paralleled the presence of GTPase activity. This strongly suggests that at least one if not all of these polypeptides constitute the GTPase. This is in essential agreement with recent findings of Godchaux and Zimmerman[16] who also assign GTPase activity to the polypeptide doublet of MWs 37,000 and 35,000 (which they term 41K and 37K).

The data in Table 2 show that light changes the interaction between the GTPase and ROS membranes even in moderate ionic strength conditions where the enzyme is membrane-bound both in darkness and light (extracts D1, L1). Bleaching membranes suspended in 100 mM Tris buffer prevents the enzyme from being extracted in the dark by a subsequent treatment with 5 mM Tris (extract L2), whereas the enzyme from a similarly treated unbleached sample can be extracted in the same conditions (extract D2). It seems likely, therefore, that significant light-induced changes in the binding of the GTPase to ROS membranes occur also in physiological ionic strength conditions.

Table 2 Effect of the ionic strength on the extractability of GTPase from unbleached and bleached ROS

Treatment of ROS suspension before centrifugation	Light conditions	Extract	GTPase activity of extracts
First extraction			
ROS vigorously homogenised in 100 mM Tris and divided into two samples for dark (D)	Dark	D1	1.64
and light (L) extraction	Light	L1	1.05
Second extraction			
Pellets resulting from the first extraction	Dark	D2	20.0
resuspended in 5 mM Tris	Dark	L2	0.45

The conditions of illumination and centrifugation were as described in Fig. 1. The time elapsed between the first and second centrifugation step was 15 min during which the membranes were kept in the dark mostly at 0–4 °C. Both buffers contained 0.5 mM $MgCl_2$, 1 mM dithiothreitol, and 0.05 mM phenylmethylsulphonyl fluoride in addition to the Tris–HCl (*p*H 7.4; 100 mM or 5 mM, respectively). Neither of the extracting buffers contained GTP. The homogenisation treatment was sufficient to disrupt the ROS structure such that most of the soluble proteins were eluted in 100 mM Tris buffer, except the polypeptides of MWs 95,000 (doublet), 37,000, 35,000 and 6,000 which are membrane-bound at this ionic strength. The latter five polypeptides were found enriched in the subsequent hypotonic extract D2, whereas L2 contained only the doublet of MW 95,000 (gels not shown). GTPase activity was measured and is expressed as for Table 1.

The light-induced binding of the GTPase and its specific elution with GTP offers a unique way of purifying this enzyme. Bleached ROS are washed extensively to remove soluble proteins (Fig. 1*e*, *m*, *n*) and are then incubated with 40 μM GTP in hypotonic buffer. The resulting extract contains high GTPase activity if assayed in the presence of added bleached ROS, and the only polypeptides present are those of MWs 37,000, 35,000, and about 6,000 (Fig. 1*o*, *p*; Table 1*o*). The yield of purified GTPase is 60–70 μg of each of the two large polypeptides (MWs 37,000 and 35,000) per mg of rhodopsin; this indicates that at least 6–7 molecules of each polypeptide are present per 100 rhodopsin molecules in ROS.

The phenomenon of light-induced changes in the interaction of certain ROS proteins with the photoreceptor membrane may well reflect the mechanism by which enzymes in ROS are light-activated via bleaching of rhodopsin. To support this hypothesis, it would be important to know how rapidly the light-induced binding changes occur. Preliminary experiments[15] indicate that, even at 0 °C, both the light-induced binding and the GTP-induced release of the GTPase occurs faster than the time resolution of the centrifugation method (10–15 min). This leaves open the possibility that, at physiological temperatures, the observed changes in molecular interactions of ROS proteins may be fairly fast reactions.

I thank Ms O. Mommertz for technical assistance, and Drs H. G. Smith, P. A. Hargrave and M. Chabre for critical reading of the manuscript. This work was supported by grant SFB 160 from Deutsche Forschungsgemeinschaft.

Epithelial cells in nerve-free hydra produce morphogenetic substances

H. C. Schaller*, T. Rau & H. Bode†

European Molecular Biology Laboratory, Postfach 10.2209,
6900 Heidelberg, FRG

It has been shown that hydra, consisting almost exclusively of epithelial cells, have normal morphogenetic properties. This means that they are able to reproduce asexually by budding and to regenerate head or foot with conservation of the original polarity. Such hydra have no interstitial cells and they lack nerves and nematocytes as differentiation products of the interstitial stem cell. Consequently, they are unable to catch or ingest food and would not survive in nature. However, stocks can be maintained in the laboratory, if food is injected into the gastric cavity[1–3]. The fact that nerve-free hydra would grow and regenerate normally raised some doubts as to the role of the nervous system in the control of differentiation and development in hydra. In particular, the significance of morphogenetic substances, such as the head activator[4], which is normally produced by nerve cells[5], seemed to need reassessment[6]. We now show that epithelial cells in hydra have the potential to produce head activator and other morphogenetic factors, but that this property is repressed in the presence of nerves.

In a preliminary investigation we have shown that severely nerve-depleted hydra, which consist almost exclusively of epithelial cells, contain normal concentrations of morphogenetic substances[7]. To exclude the possibility that the few remaining nerve cells overproduce these substances, we have repeated the experiments with completely nerve-free hydra. These were from two sources: the first 100 were from Richard Campbell from a

Table 1 Cell composition of nerve-free and normal hydra

Animal	Total cells (%)	Epithelial	Gland and mucous	Interstitial	Nematocyte lineage	Nerve
Nerve-free	14,700	13,500	660	320	210	0
	(100)	(91.8)	(4.5)	(2.2)	(1.4)	0
Normal	62,300	13,800	3,930	7,100	34,300	3,200
	(100)	(22.0)	(6.3)	(11.4)	(55.0)	(5.1)

stock originally produced by colchicine treatment and had been nerve free for more than a year[8]. The next 300–400 nerve-free hydra we produced ourselves following C. N. David's suggestion of selecting non-feeding animals from the normal culture and force-feeding them by hand. Such animals are probably the result of interstitial stem-cell depletion caused by an excessive differentiation into nerves or nematocytes or, experimentally induced, into sexual cells. Such animals were not interstitial-cell free, and they contained a few remaining nerve cells, but they produced offspring which in most cases was completely nerve free. Such nerve-free hydra were easily recognisable by their characteristic shape, with many undetached buds, swollen heads and short tentacles (Fig. 1*a*), by their inability to catch food and by their lack of reaction against tactile stimuli such as tickling the tentacles with a needle[9]. To standardise size we selected animals in which a first bud was just visible (Fig. 1*b*). Such standard animals consisted on average of 15,000 ± 2,000 cells, of which more than 90% were epithelial cells (Table 1).

Table 2 Amount of material necessary to achieve the effect corresponding to 1 biological unit (BU)

Morphogen	Nerve-free hydra	Normal hydra	Ratio
Head activator	0.009	0.075	8.3
Head inhibitor	0.009	0.033	3.7
Foot activator	0.05	0.09	1.8
Foot inhibitor	0.14	0.11	0.8

The amount of material is given in A_{280} units per ml. One standard nerve-free hydra, if homogenised in 1 ml, yielded on average 0.14 A_{280} units and one standard normal hydra 0.15 A_{280} units. One biological unit is defined as the amount of material necessary in 10 ml of medium to achieve for the head activator a 6% increase in tentacle number, a 50% increase in bud outgrowth, or a 33% acceleration in head-regeneration rate, for the head inhibitor a 50% decrease in bud outgrowth or a 33% inhibition of head-regeneration rate, for the foot activator a 50% acceleration and for the foot inhibitor a 25% inhibition of the foot-regeneration rate[10].

From these hydra we made crude extracts and assayed them directly and after purification for content of head activator, head inhibitor, foot activator and foot inhibitor[10]. We found that nerve-free hydra contain eight times more head activator, four times more head inhibitor, twice as much foot activator and a little less foot inhibitor than normal animals (Table 2). No difference was found in the head-activator concentration of nerve-free hydra originating from the two sources. From this we conclude that cell types other than the nerve cells can produce morphogenetic substances. The cell composition shown in Table 1 reflects the status of animals that have been nerve free for a few generations. The longer such animals are propagated by force-feeding, the more they lose cell types other than the epithelial cells, such that in the end they consist exclusively of epithelial cells. As Campbell's animals had reached that stage, we are sure that it is the epithelial cell which is producing morphogenetic substances. Campbell and Marcum produced nerve-free hydra by colchicine treatment[8], and Sugiyama *et al.* selected for an interstitial-cell-free mutant by sexual inbreeding[3]. The fact that our animals were asexual offspring from normal hydra, not treated with chemicals or mutagens and not the result of sexual crosses, suggests that the ability to produce morphogenetic substances is an inherent property of epithelial cells and not the result of a mutation or chemical mistreatment.

We had shown earlier that in normal animals most of the head activator (80–90%) is located in nerve cells[5]. This did not exclude the possibility that the remaining 10–20% may be present in another cell type. To obtain direct evidence on the occurrence of head activator in normal epithelial cells a procedure was devised for separating nerves from epithelial cells. Hydra were dissociated into viable cells according to the method described in Trenkner *et al.*[11]. Epithelial cells were separated from nerve cells using sedimentation velocity centrifugation in Percoll gradients. Because the two cell types differ greatly in size (average nerve cell and epithelial cell diameters are 6.0 and

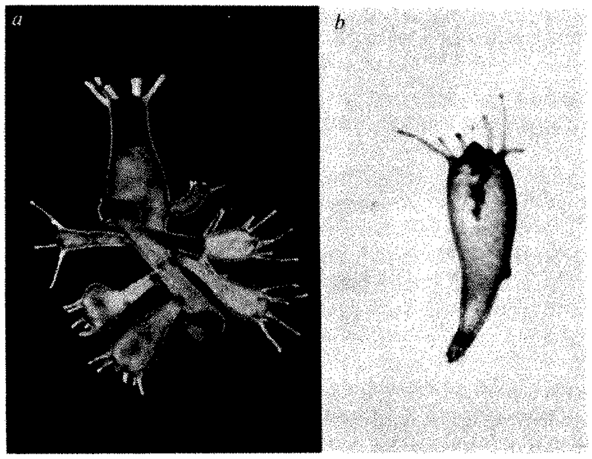

Fig. 1 Nerve-free hydra. *a*, Mother animal with several buds which need much longer to detach than normal buds. Each individual bud has to be force-fed by hand. *b*, Standard animal which started to develop its first bud.

Table 3 Head activator in cell fractions enriched for epithelial or nerve cells

Animal	Cell fraction	Cell composition (×10⁶) Total	Epithelial	Nerve	Content of head activator (BU)
Normal	Unseparated	90.0	20.0	4.5	400
	Epithelial enriched*	9.4	6.0	0.06	35
	Nerve-enriched†	5.3	1.9	2.8	320
Nerve-free	Unseparated	3.8	3.5	0	400

* 2–3 × 10⁶ cells were layered over an 8-ml linear Percoll gradient with a density range of 1.01–1.02, and separated by centrifugation at 300*g* for 10 min. Cells in the lower one-third of the gradient plus the pellet were pooled.

† Nerve cells were enriched using glycerol gradients as described earlier[5,12].

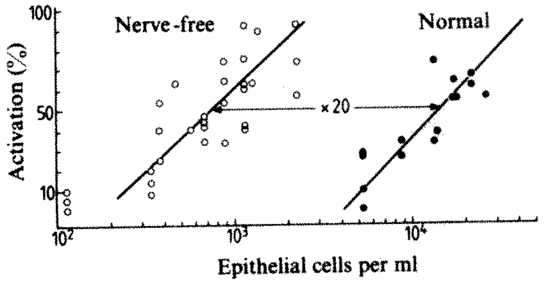

Fig. 2 Head activator in epithelial cells of nerve-free and normal hydra.

15.6 µm, respectively), a fraction could be obtained consisting mostly of epithelial cells and containing very few nerves (Table 3). From an epithelial-cell-enriched fraction a crude extract was prepared, and after purification on G-10, assayed for content of head activator. We found that it contained ~9% of the head activator present in unseparated cells (Table 3). Because only 1% of the nerve cells were represented in this fraction, we conclude that a minor portion of the head activator may be produced in normal animals also, by cell types other than the nerve cells, possibly epithelial cells. Figure 2 compares the content of head activator per epithelial cell in this isolated epithelial cell fraction from normal animals with that in nerve-free hydra. The results show that epithelial cells from nerve-free hydra contain at least 20 times more head activator than epithelial cells of normal animals. This is interpreted to mean that epithelial cells in normal animals may have the capacity to produce morphogenetic substances, but that this capacity is repressed in the presence of nerve cells.

Thus, our findings indicate that nerve-free hydra contain the same morphogenetic substances as normal hydra. One argument arainst a morphogenetic role for these substances was that they are neurohormones and are involved in a regulation imposed by the nervous system. The finding that no major difference exists in the morphogenetic properties between normal and nerve-free hydra supports the notion that hydra and morphogenetic substances in hydra are a good model for studying pattern formation in embryological systems.

We thank R. D. Campbell and M. Chow for providing us with nerve-free hydra, T. Schmidt for assaying the foot inhibitor, and the Deutsche Forschungsgemeinschaft and the Alexander von Humboldt-Stiftung for support.

Expression of herpesvirus-induced antigens in human cervical cancer

Gordon R. Dreesman, Joyce Burek, Ervin Adam, Raymond H. Kaufman & Joseph L. Melnick

Departments of Virology and Epidemiology, and of Obstetrics and Gynecology, Baylor College of Medicine, Houston, Texas 77030

Kenneth L. Powell & Dorothy J. M. Purifoy

Department of Microbiology, University of Leeds, Leeds, UK

Herpes simplex virus type 2 (HSV2) was first associated with human cervical cancer by seroepidemiologic studies over 10 years ago, but there has been no clearcut evidence confirming or refuting the role of the virus in this cancer. Expression of HSV antigens in cells transformed *in vitro* by the virus has been reported by several groups[1,2]. Evidence for the association of HSV antigens with human cervical cancer has recently been reviewed[3–5]; general antisera prepared against HSV virions or structural proteins were used by several groups to screen cells derived from the cancer and equivocal results were obtained. The tumour-specific antigens associated with three known oncogenic DNA viruses—adenovirus type 2, SV40, and Epstein–Barr herpesvirus—are DNA-binding proteins[5–8]. Therefore, proteins which bind DNA were isolated[9,10] from HEp-2 cells infected by HSV2, and monospecific antisera to two of these proteins (ICSP 11/12 and ICSP 34/35) were prepared. These rabbit antisera react specifically with the nuclei of HSV2-infected cells[11]. We show here that an HSV2-specific DNA-binding antigen was expressed in 38% of tissues with pathological findings of severe dysplasia or carcinoma. This therefore constitutes further evidence for HSV2 as a factor in human cervical carcinoma.

Prepared antisera to purified HSV2 virions (anti-HSV2) anti-ICSP 11/12 and anti-ICSP 34/35, and pre-inoculation rabbit serum were used to screen human cervical tissue for the presence of HSV-specific antigens. The cervical tissues were embedded in OCT compound (Lab-Tek) and quick frozen in a cryostat. Sections (10 µm) were cut for haematoxylin/eosin (HE) staining, and additional sections (6 µm) were cut for immunological staining procedures. All HE stained slides were double-blind coded for pathological examination. Adjacent sections were stained both by indirect immunoperoxidase (IP) staining and by indirect immunofluorescence (IF) staining[12]. All of the antisera (primary and goat anti-rabbit horseradish peroxidase or fluorescein conjugates) were adsorbed with uninfected HEp-2 cells and with rabbit liver powder before use.

Tissues obtained from 124 women were screened for the presence of HSV2-specific antigens using the above sera. the results are summarised in Table 1. Whereas anti-ICSP 34/35 gave a nuclear pattern of staining with infected HEp-2 cells, all of the positive reactions observed by screening biopsy material

Table 1 Staining of human cervical biopsy sections by indirect immunoperoxidase

Diagnosis	Total tested	No. negative	No. positive	Per cent positive
Normal	15	15	—	0
Chronic inflammation	6	6	—	0
Metaplasia	27	26	1	4
Dyplasia				
Mild	35	34	1	3
Moderate	20	18	2	10
Severe	11	7	4	36
Carcinoma *in situ* and invasive	10	6	4	40

The sections were stained with rabbit anti-HSV-specific ICSP 34/35 sera.

0028-0836/80/060591—03$01.00

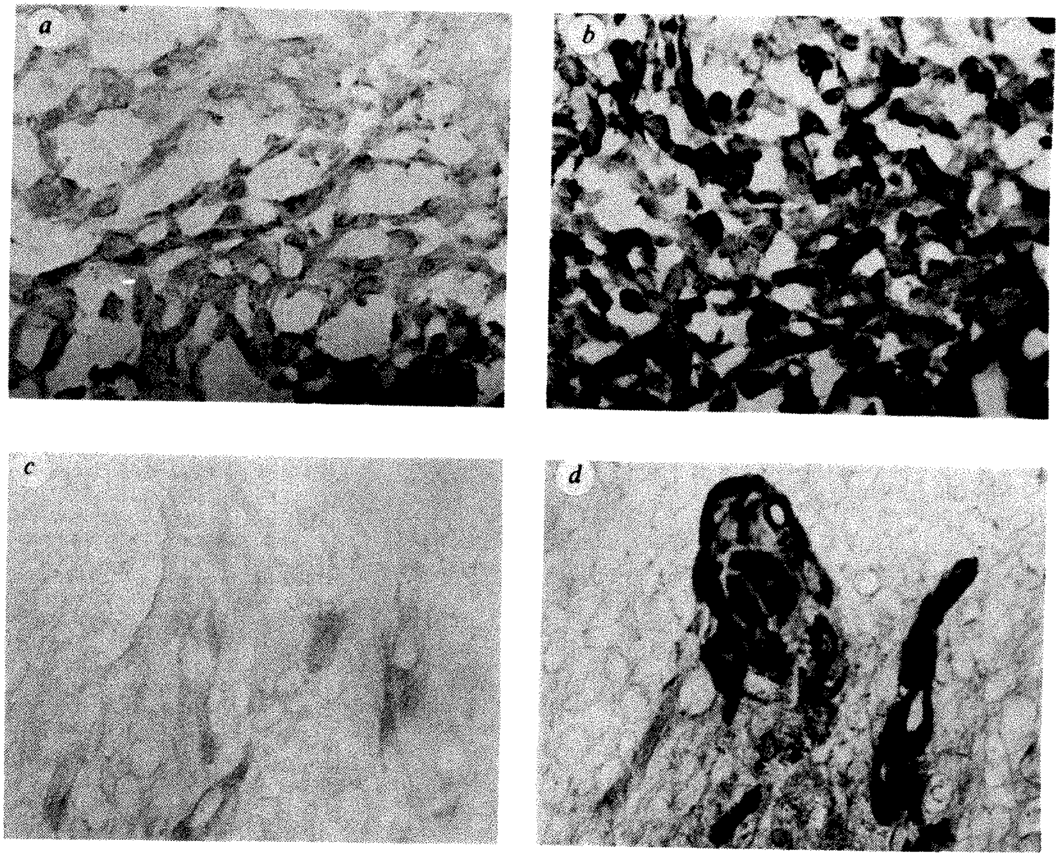

Fig. 1 Immunoperoxidase staining of human cervical tissues. *a* and *b*, Tissues were from a patient diagnosed as severe dysplasia; *c* and *d*, tissues were taken from a patient with carcinoma *in situ*. The primary antisera used were rabbit anti-ICSP 34/35 (*b* and *d*) and rabbit pre-inoculation (*a* and *c*). ×560.

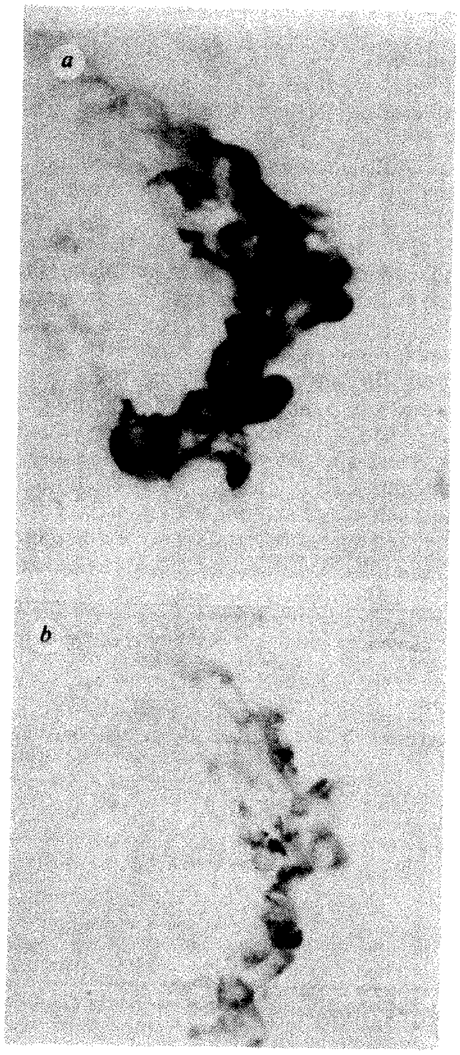

were perinuclear and cytoplasmic. Typical patterns are shown in Fig. 1. This staining pattern is similar to that observed previously by Flannery *et al.*[2], who used an antiserum designated anti-VP143 to stain a number of HSV2-transformed cell lines. The VP143 HSV2 protein has the same molecular weight as ICSP 11/12. When the tissues were stained using the IF technique, the results were the same as those given in Table 1. If the tissues are divided into two groups (group I, those with diagnoses of normal, chronic inflammation, metaplasia, mild dysplasia, and moderate dysplasia; and group II, those with severe dysplasia, carcinoma *in situ* and invasive carcinoma), the following observations can be made: the incidence of positives in group I is 4 out of 103, or 4%, and in group II is 8 out of 21, or 38%. Similar but weaker patterns were observed when the majority of the above tissues were studied using anti-ICSP 11/12. However, no reactivity was seen using antiserum to HSV2 whole virions. Comparable results have been obtained by McDougall *et al.* (personal communication) using anti-ICSP 11/12.

The specificity of the reactions has been tested by adsorbing the anti-ICSP 34/35 sera with HSV2-infected HEp-2 cell lysates. The adsorbed sera were now negative when allowed to react with infected cells. The adsorbed sera were also tested with cervical tissue sections from seven positive patients. In six cases the reaction was now negative or significantly diminished (Fig. 2*a*, *b*). In the seventh case, the reaction was essentially unchanged. The six tissues in which the reaction was blocked or significantly diminished had a pathological reading of severe dysplasia or carcinoma. The seventh tissue, the reactivity of which was not altered by blocking, was a section from tissue diagnosed as metaplasia. The significance of these patterns is being investigated in greater detail.

One tissue with a pathology report of severe dysplasia gave nuclear staining by the IP staining procedure. However, this pattern was also noted when the tissue was reacted with the

Fig. 2 Immunoperoxidase staining of a human cervical tissue with a pathological finding of moderate dysplasia. The primary antiserum used was rabbit anti-ICSP 34/35 before (*a*) and after (*b*) adsorption with HSV2-infected cell lysates. ×560.

anti-HSV2 virion serum, as well as with an anti-HSV1 serum. There was only one localised area in the tissue that contained cells which gave this nuclear pattern of staining.

In summary, an HSV2-specific DNA-binding antigen was expressed in 38% of tissues with pathological findings of either severe dyplasia or carcinoma. This is of additional interest as these same tissues are negative when examined with an anti-virion HSV2 serum. The specificity of the reactivity for HSV DNA-binding protein antigen was demonstrated in that (1) pre-inoculation rabbit serum gave no reaction; (2) 21 tissues with no pathological changes were negative; (3) adsorption of the anti-ICSP 34/35 serum with HSV2-infected cell lysate blocked the reaction; and (4) adsorption with lysates of uninfected HEp-2 cells did not alter the reactivity. Our data lend support to a previous finding that about 60% of human cervical tumours contain HSV mRNA[13]. These fingerprints add further evidence for HSV2 as a factor in human cervical carcinoma.

(ADP–ribose)$_n$ participates in DNA excision repair

Barbara W. Durkacz, Olusesan Omidiji, Douglas A. Gray & Sydney Shall

Biochemistry Laboratory, University of Sussex, Brighton,
Sussex BN1 9QG, UK

Chromatin proteins are covalently modified by at least five different processes; in no case has the precise physiological function been established. One of these post-synthetic, covalent modifications is effected by the enzyme poly(ADP–ribose) polymerase, which uses the coenzyme NAD$^+$ to ADP-ribosylate chromatin proteins[1–3]. The modification consists largely of mono(ADP–ribose), but long, homopolymer chains of (ADP–ribose) are also present. Various physiological functions have been suggested for (ADP–ribose)$_n$. Here we demonstrate that one function of (ADP–ribose)$_n$ is to participate in the cellular recovery from DNA damage. Specific inhibitors of poly(ADP–ribose) polymerase prevent rejoining of DNA strand breaks caused by dimethyl sulphate and cytotoxicity is enhanced thereby. The rejoining of strand breaks is prevented also by nutritionally depleting the cells of NAD.

Both radiation[4–6] and alkylating agents[7–10] lower the cellular NAD content. An explanation for this phenomenon was suggested when we showed that the nitrosourea, streptozotocin, both lowered cellular NAD content and raised the specific activity of poly(ADP–ribose) polymerase[9]. Treatment of cells with *N*-methyl-*N*-nitrosourea or with γ-radiation results in a profound drop in cellular NAD content, and this decrease is correlated with enhanced activity of poly(ADP–ribose) polymerase[10–12]. The enzyme activity also increases when permeabilised cells are incubated with either endogeneous[13] or exogeneous endonucleases[13,14]. Poly(ADP–ribose) polymerase activity increases in human lymphoblastoid cell lines after UV irradiation, and this response is abolished or delayed in xeroderma pigmentosum cells, which are unable to excise pyrimidine dimers[15]. Thus DNA fragmentation seems to activate poly(ADP–ribose) polymerase, thereby decreasing the cellular NAD content[13].

Four chemical classes of inhibitors of poly(ADP–ribose) polymerase are known; nicotinamides (such as 5-methylnicotinamide)[16–18], methylxanthines[10,11,19,20], thymidine[16,21] and aromatic amides such as benzamides (refs 21, 22, and G. Khan and S.S. unpublished results). The inhibition constant (K_i) for 3-aminobenzamide in isolated L1210 nuclei has been estimated to be 1.8 ± 0.2 μM (M. Purnell and W. J. D. Whish, personal communication). We have confirmed that 3-aminobenzamide is a very powerful, competitive inhibitor of poly(ADP–ribose) polymerase. The K_i in permeabilised[13] L1210 mouse leukaemic lymphoblast cells, at 26 °C is 4.4 ± 1.1 μM. This enzyme inhibitor is non-toxic to these L1210 cells at up to 3 mM, as shown by a cloning assay in soft agar. Two enzymes catabolise NAD in eukaryotes—NAD glycohydrolase (EC 3.2.2.6) and poly(ADP–ribose) polymerase. 3-Aminobenzamide does not inhibit NAD glycohydrolase in our system. As 3-aminobenzamide does not reduce the cloning efficiency of these cells, it is likely that it does not have profound metabolic effects of an unknown character in undamaged cells.

The cellular NAD content is lowered by dimethyl sulphate (DMS) in a dose-dependent manner (Fig. 1*a*), reaching the minimum level in 1 to 2 h of treatment. Poly(ADP–ribose) polymerase activity in nucleotide-permeable cells[13] after DMS treatment increases (threefold at 1 mM DMS) in a dose-dependent way and shows a peak of activity when the NAD content is dropping most rapidly (Fig. 1*c*).

At 1 mM, 3-aminobenzamide prevents the NAD decrease completely, while the non-inhibitor, 3-aminobenzoic acid, has no effect (Fig. 1*b*). The decrease in NAD induced by DMS is also inhibited by 5-methylnicotinamide, thymidine/deoxycytidine and theophylline, but not by nicotinic acid (data not shown). Neither 5-methylnicotinamide nor thymidine/deoxycytidine significantly inhibit NAD glycohydrolase[12]. The decrease in NAD content induced by DNA-damaging agents is mediated by poly(ADP–ribose) polymerase; thus (ADP–ribose)$_n$ may be implicated in some aspect of DNA repair.

We have therefore examined the kinetics of removal of single-strand breaks (this includes breaks produced by the alkaline conditions of the gradient) following treatment with DMS. Immediately after treatment, the DNA sediments as a broad peak in the middle of the gradient (Fig. 2*c*, *a*). At 40 min after removal of the DMS, the DNA is increased significantly in size (Fig. 2*c*), and by 80 min it is completely converted into a fast sedimenting complex near the bottom of the gradient, which is the position at which undamaged DNA sediments (Fig. 2*d*).

However, when the enzyme inhibitor 3-aminobenzamide (3 mM) is added to the cells following removal of DMS, conversion of the low molecular weight DNA to a fast-sedimenting material is almost completely inhibited (Fig. 2*a*, *b*). There is no observable increase in molecular weight of the DNA 40 min after removal of DMS (Fig. 2*a*). After 80 min, the DNA is increased slightly in size, but still sediments in the middle of the gradient (Fig. 2*b*). Even after 5 h the bulk of the DNA has not yet returned to its original size (Fig. 2*b*). Addition of 3 mM 3-aminobenzoic acid does not retard excision repair following DMS treatment (data not shown).

Other inhibitors of the polymerase also inhibit excision repair in these cells. Both 5-methylnicotinamide and thymidine (in the presence of deoxycytidine) are effective inhibitors of excision repair (data not shown). Thus we have demonstrated that inhibitors of the enzyme, poly(ADP–ribose) polymerase, inhibit excision repair in these cells.

If (ADP–ribose)$_n$ biosynthesis participates in the cellular recovery from DNA damage, then inhibition of (ADP–ribose)$_n$

0028-0836/80/060593—04$01.00

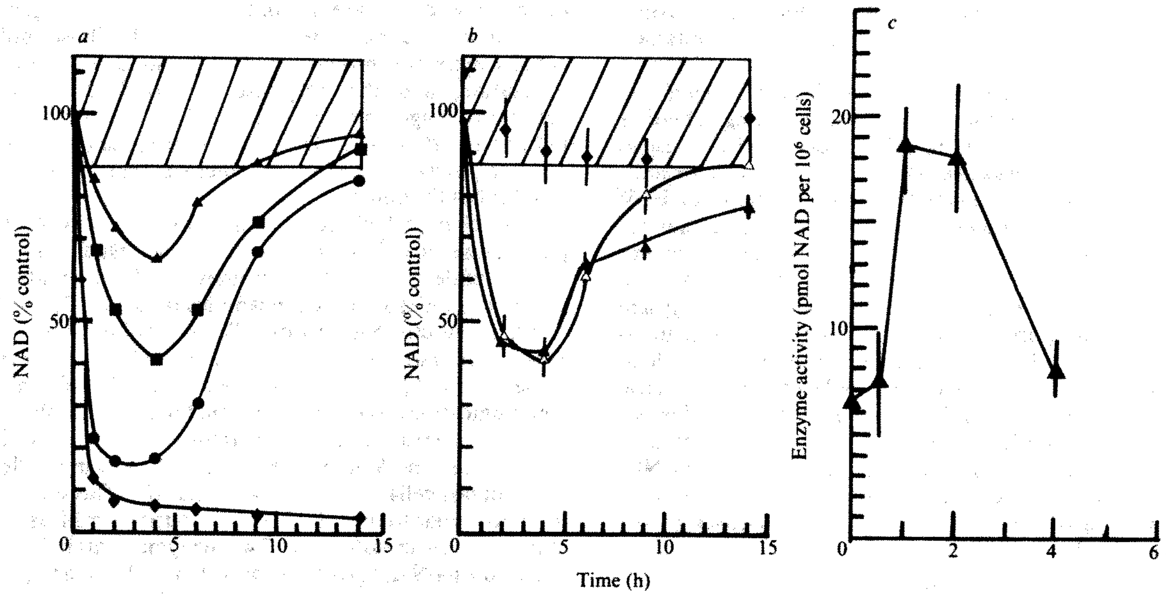

Fig. 1 The effect of DMS and of poly(ADP–ribose) polymerase inhibitors on the NAD content of L1210 cells. *a*, Cells were continuously treated with increasing doses of DMS, and samples were removed at intervals for NAD assay, washed once with 0.9% (w/v) NaCl, resuspended in cold 50% (v/v) ethanol, and then sonicated for 20 s (medium power, amplitude 1, MSE sonicator). Each sample was assayed for NAD in duplicate by a modification of the method of Nisselbaum and Green[12]. ▲, 10.5 μM DMS; ■, 52.6 μM; ●, 105.3 μM; ◆, 210.6 μM. *b*, L1210 cells were continuously treated with 53 μM DMS either alone (△) or in the continuous presence of either 2 mM 3-aminobenzamide (◆) or of 2 mM 3-aminobenzoic acid (▲). Samples were removed at intervals for NAD estimation[12]. *c*, Cells were treated continuously with 1 mM DMS and then the poly(ADP–ribose)polymerase activity was determined at the indicated times. Permeabilised cells[13] were cooled to 4 °C, collected by centrifugation in the cold and washed once with cold Pucks saline (containing 400 mg l^{-1} KH_2PO_4, 350 mg l^{-1} $NaHCO_3$, 8 mg l^{-1} NaCl, and 1 g l^{-1} glucose at *p*H 7.4). The cells were resuspended in a cold hypotonic buffer *p*H 7.8, (containing 9 mM HEPES, 4.5% (w/v) dextran, 1 mM EGTA, 4.5 mM $MgCl_2$, and 5 mM DTT). The cell concentration in this hypotonic buffer was $3–5 \times 10^7$ per ml. After 30 min incubation at 4 °C the cells were diluted 10-fold with an isotonic buffer *p*H 7.8 (containing 40 mM HEPES, 130 mM KCl, 4% (w/v) dextran, 225 mM sucrose, 2 mM EGTA, 2.3 mM $MgCl_2$ and 2.5 mM DTT). 250 μl of cells were incubated at 25 °C with 5 μl of ^3H-NAD (final concentration 2 μCi ml^{-1}, 100 μM). Triplicate samples were taken at 2-min intervals up to 8 min. The reaction was stopped with 4 ml of 20% (w/v) trichloroacetic acid (TCA). The samples were left at 4 °C for 4 h, filtered on to glass fibre disks and washed four times with 10% (w/v) TCA, and twice with acetone. The filters were dried and the radioactivity estimated in a toluene-PPO scintillant in a Beckman LS233 liquid scintillation counter. Enzyme activity was estimated by least squares regression analysis. The control level of poly(ADP–ribose) polymerase in these conditions was 6.63 ± 0.94 (s.d.) pmol min^{-1} per 10^6 cells (nine determinations).

biosynthesis would be expected to increase the toxicity (and perhaps also the mutagenicity) of DNA-damaging agents.

Exposure of L1210 cells to DMS for 1 h results in a dose-dependent cytotoxicity (Fig. 3). 90 μM DMS yields a 10% survival. However, the toxicity of DMS is greatly increased when 2 mM 3-aminobenzamide is present during both exposure of the cells to DMS and in the subsequent cloning assay. In these conditions 22 μM DMS is sufficient to give 10% survival; this represents a fourfold dose-enhancement. 3-Aminobenzoic acid (2 mM) has no effect on the cytotoxicity of DMS (Fig. 3). In addition, 5-methylnicotinamide, thymidine/deoxycytidine and theobromine potentiate the cytotoxicity of DMS (O.O. and S.S., manuscript in preparation).

This potentiation of cytotoxicity is observed also with several other monofunctional alkylating agents, and with representatives of each class of enzyme inhibitor (N. Nduka, O.O., A. A. Zia'ee and S.S., manuscripts in preparation).

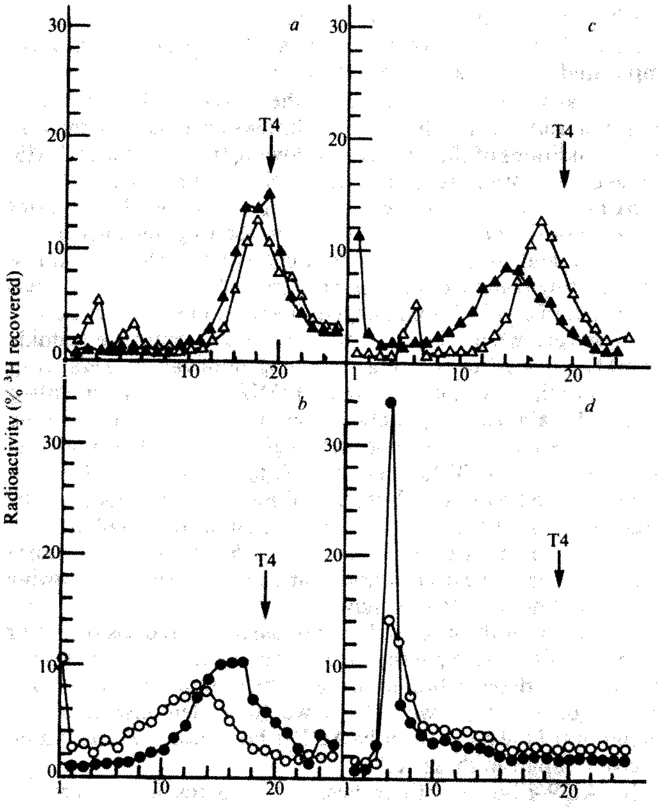

Fig. 2 The effect of 3-aminobenzamide on excision repair in L1210 cells. L1210 cells were prelabelled for 18 h (1.5 generations) with 1 μCi ml^{-1} ^3H-thymidine, 1 μM total thymidine. The radioactivity was washed out and the cells were treated with 100 μM DMS for 20 min. The cells were collected and resuspended in RPMI 1640 medium and incubated at 37 °C. Samples of 1 ml were removed at intervals, centrifuged and resuspended in cold phosphate-buffered saline and kept on ice. Samples of 25 μl ($1–2 \times 10^4$ cells) were taken for each time point and layered on a lysis layer (100 μl 2% (w/v) SDS, 10 mM EDTA) over a 4.8 ml to 20% (w/v) sucrose gradient (100 mM NaCl, 100 mM NaOH). The gradients were centrifuged for 1 h at 20 °C in a SW 50.1 Beckman rotor at 25,000 r.p.m. Fractions (12 drops) were collected on filter strips and the TCA-insoluble radioactivity was estimated. Time after removal of DMS: ■, 0 min; □, 40 min; ○, 80 min; ●, 300 min. The total radioactivity loaded onto the gradients was $\sim 2 \times 10^4$ c.p.m.; recovery was between 80 and 100%. *a*, The cells were exposed to DMS for 20 min, which was washed out, but 3 mM 3-aminobenzamide was added to the medium for the 300 min recovery period. *b*, The cells were exposed only to DMS. The arrow shows the position of a ^{14}C-labelled bacteriophage T4 DNA, single-stranded of molecular weight 55×10^6.

The evidence that (ADP-ribose)$_n$ biosynthesis participates in cellular recovery from DNA damage rests heavily on experiments with enzyme inhibitors. Although we show that all four classes of polymerase inhibitors are effective, the possibility remains that all these polymerase inhibitors might also coincidentally inhibit some aspect of DNA repair directly. Therefore, we have tested the ability of cells to carry out excision repair when the cellular NAD content is lowered by nutritional deprivation. NAD levels of cells may be depleted by growing them in a nicotinamide-free medium[23]. Even with quite low NAD content (10–20% of normal) the L1210 cells continue to grow and divide at the normal rate. The rate of incorporation of ^{3}H-thymidine by these NAD-depleted cells is the same as that of cells grown either in complete medium or in depleted medium supplemented with nicotinamide for 4 h. The NAD content of L1210 cells is 750 pmol per 10^6 cells; the NAD concentration is therefore about 1,000 μM. The K_m value for the DNAase-activated[24] polymerase in permeabilised cells[13] is 328 ± 127 μM. Thus, lowering of the NAD content should decrease the activity of the enzyme, and therefore inhibit DNA repair.

After exposure to 100 μM DMS, the DNA in NAD-depleted cells becomes fragmented (Fig. 4*a*), and not only is strand-rejoining inhibited, but the DNA is further decreased in size during the subsequent 80 min (Fig. 4*a*). This inhibition of recovery is alleviated if the cells are pre-incubated for 4 h in the presence of nicotinamide before DMS treatment (Fig. 4*b*).

NAD-depleted cells in the presence of hydroxyurea do not display unscheduled DNA synthesis after treatment with methylnitrosonitroguanidine[32].

The evidence that (ADP-ribose)$_n$ is involved in DNA repair can be summarised as follows. Both alkylating reagents and radiation lower cellular NAD contents, and they both elevate poly(ADP-ribose) polymerase activity. The drop in NAD content and the rejoining of strand breaks after treatment with DMS are inhibited by 3-aminobenzamide and the other poly(ADP-ribose) polymerase inhibitors, all of which potentiate the cytotoxicity of the alkylating agent. In addition, cells that are nutritionally deprived of NAD cannot efficiently execute excision repair. *N*-methyl-*N*-nitro-*N*-nitrosoguanidine lowers cellular NAD levels and increases intracellular poly(ADP-ribose) levels[33].

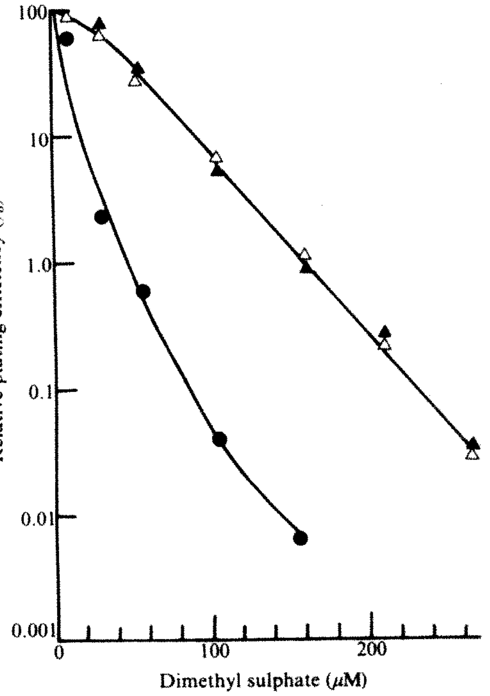

Fig. 3 The effect of 3-aminobenzamide on the cytotoxicity of DMS towards L1210 mouse leukaemia lymphoblast cells. Cells were treated with increasing doses of DMS alone for 1 h at 37 °C (△), or with DMS for 1 h in the continuous presence of either 2 mM 3-aminobenzamide (●) or 2 mM 3-aminobenzoic acid (▲). Cells were plated in 0.5% (w/v) agar in RPMI 1640 medium supplemented with 20% (v/v) horse serum in the absence or presence of the inhibitors, respectively. For DMS alone, the points are the means of nine experiments, each with five plates per point; for the other two situations the points are the means of two experiments each with five plates per point.

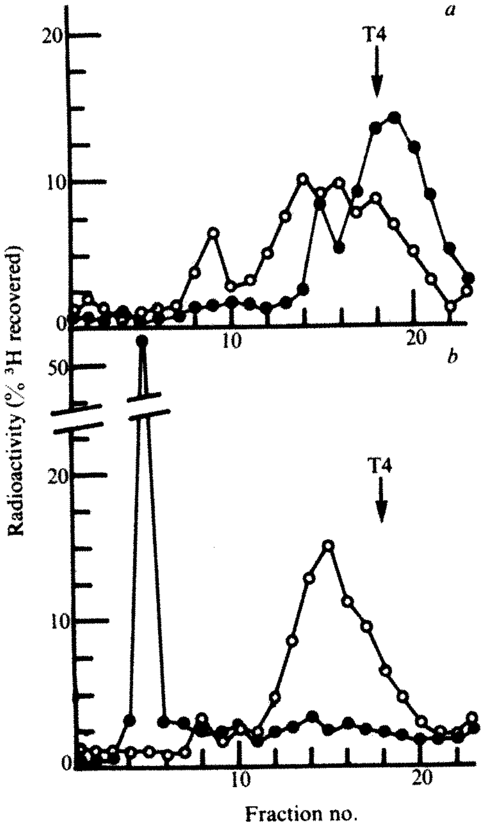

Fig. 4 The effect of NAD depletion on excision repair. Cells were grown for four generations in medium from which nicotinamide was omitted, and the serum was extensively dialysed against phosphate-buffered saline. NAD assays showed that the NAD content was 10 to 20% of the control levels. The culture was divided into two aliquots and nicotinamide was added to one to a concentration of 9 μg ml^{-1}. The cells were exposed 4 h later to 100 μM DMS for 20 min and then their ability to carry out excision repair was tested as described in the legend to Fig. 2. Time: ○, 0 min; ●, 80 min. *a*, NAD-depleted cells. *b*, Nicotinamide added back; the NAD level had returned to normal.

The mechanism involved when (ADP-ribose)$_n$ participates in the cellular recovery from DNA damage is not yet understood. Two general types of mechanism may be considered. A protein (enzyme) specifically involved in the molecular DNA repair mechanism may be activated or inhibited by ADP-ribosylation. For example, ADP-ribosylation of a Ca^{2+},Mg^{2+}-dependent endonuclease results in the reversible inhibition of nuclease activity[25]. Alternatively, ADP-ribosylation of either a specific or a nonspecific set of chromatin proteins would profoundly alter local chromatin structure. It has been suggested that (ADP-ribose)$_n$ may have cross-linking properties, or may be involved in extending and condensing chromatin[26–30]. Cell extracts from some complementation groups of xeroderma pigmentosum can excise pyrimidine dimers from naked DNA but not from chromatin[31]; this implies a need for chromatin structural alterations in excision repair.

Our results show that (ADP-ribose)$_n$ biosynthesis is required for efficient excision repair and survival, following damage with monofunctional alkylating agents. The dramatic synergistic potentiation of cell killing by alkylating agents and poly(ADP-ribose) polymerase inhibitors may be of use in the treatment of human leukaemia.

Mutagenicity of carcinogenic methylating agents is associated with a specific DNA modification

R. F. Newbold, W. Warren, A. S. C. Medcalf & J. Amos

Chemical Carcinogenesis Division, Institute of Cancer Research,
Pollards Woods Research Station, Nightingales Lane, Chalfont St Giles,
Bucks HP8 4SP, UK

The carcinogenic potency of simple aliphatic alkylating agents such as the alkylnitrosamides and the alkylmethanesulphonates is positively correlated with their ability to alkylate the relatively weakly nucleophilic oxygen atoms in DNA, particularly the O^6-atom of guanine[1–4]. Differences in the spectrum of DNA alkylations produced by these agents can be rationalised on chemical grounds in that the electrophilic reactivity of the alkylating species determines the extent to which it will react at sites of weaker nucleophilicity[4–6]. Alkylation of the more strongly nucleophilic ring nitrogen atoms of the purine bases, which is the main site of reaction with all these agents, appears to be much less important in alkylation carcinogenesis. O^6-alkylation of guanine is likely to interfere with DNA base-pair hydrogen bonding[7] and is possibly the major DNA modification responsible for the induction of GC → AT transition mutations in bacteria and bacteriophage by alkylating agents[8–10]. Here, we have studied the effects of three methylating agents of contrasting carcinogenic potency on mammalian (V79 Chinese hamster) cells in culture. We report that the mutagenicity but not the cytotoxicity of each agent reflects its carcinogenicity and, furthermore, that the marked differences in mutagenicity are closely paralleled by differences in levels of O^6-guanine methylation.

The somatic mutation theory of cancer requires that all carcinogens be mutagens and that there be some quantitative relationship between their carcinogenicity and mutagenicity. To test this prediction, we have developed reliable and efficient methods for measuring carcinogen-induced gene mutation frequencies in cultured mammalian cells, based on classical drug-resistance markers, along with techniques for the isolation and chemical analysis of carcinogen-modified DNA. We have previously used the induction of 8-azaguanine-resistant (azg^r) and ouabain-resistant (oua^r) V79 Chinese hamster cells to define the relationship between carcinogenicity, mutagenicity and DNA reaction for various polycyclic hydrocarbon carcinogens[11–14]. In particular, *anti*-benzo(*a*)pyrene-7,8-dihydrodiol-9,10-oxide, the proposed ultimate carcinogenic metabolite of benzo(*a*)pyrene, was an exceptionally potent mutagen in this system[12]. Since V79 cells do not excise O^6-methylguanine from their DNA (ref. 15), they are also ideal for use in experiments designed to establish the role of this base in the mutagenicity and cytotoxicity of methylating agents. For the present investigation, we selected three methylating agents: dimethylsulphate (DMS) and methylmethanesulphonate (MMS) both relatively weak carcinogens and *N*-methyl-*N*-nitrosourea (MNUA), a highly potent carcinogen[16]. Quantitation of cytotoxicity and mutation induced by these compounds, coupled with high-pressure liquid chromatography of hydrolysed DNA from cells treated with radiolabelled MNUA and DMS, has enabled the modification specifically responsible for their mutagenic effects to be identified.

The results of several experiments in which the mutagenic effects of DMS, MMS and MNUA were compared in identical experimental conditions are summarised in Fig. 1. Parallel cultures of exponentially dividing V79 cells were exposed for 3 h to a range of concentrations of each compound, and replicate samples were plated for determination of induced cytotoxicity and frequency of azg^r and oua^r mutants; the experimental details are given in the legend to Fig. 1. With all three compounds a similar type of dose–survival curve was obtained, comprising a shouldered (quasi-threshold) region at low doses followed by a steeper portion where survival dropped rapidly with increasing dose. However, the dose range required to achieve this response varied approximately in the ratio 1:3:6 for DMS, MMS and MNUA respectively, the corresponding D_{37} values being 0.11 mM, 0.32 mM and 0.73 mM. The mutational response did not reflect the differences observed between the compounds in survival experiments; MNUA was by far the most potent agent at inducing both azg^r and oua^r clones. With all three compounds, dose–response curves for the induction of oua^r mutants were linear (above 10% survival where mutation frequencies could be measured most accurately) while those for azg^r mutants were cumulative. The contrasting mutagenicity of the agents was more clearly illustrated if induced mutation frequencies were plotted as a function of the logarithm of the corresponding percentage survival, as in Fig. 1. These plots were linear, as routinely found with other classes of mutagen[14,17]; lines of best fit were determined by least-squares linear regression analysis. The ratio of the slopes of these lines (mutagenic efficiency[14,18], or mutagenicity per lethal event) of MNUA relative to DMS, was approximately 15:1 for azg^r mutants and 9:1 for oua^r mutants. Although MMS was less potent than DMS as a mutagen in terms of applied dose (mutagenic effectiveness[14,18]) the two agents were indistinguishable when their mutagenicity was expressed as a function of induced cytotoxicity. This is explained by the fact that the rate of reaction of DMS is faster than that of MMS (half-time for reaction with DNA *in vitro* is 16 min compared with 5 h) although both agents share similar reaction mechanisms and produce similar proportions of the various methylated DNA products[4,19]. To confirm that only true mutants were scored in this series of experiments, mutant clones were isolated at random from plates and the cells grown in mass culture. All clones isolated remained fully resistant to the drug used to select them even when propagated for many generations in its absence. In addition, cells possessing the azg^r phenotype invariably had markedly reduced or undetectable amounts of the purine salvage enzyme hypoxanthine-guanine phospho-

Table 1 Extent of methylation of V79 cell DNA at major sites following exposure of cells in culture for 3 h to ^{14}C-DMS and ^{14}C-MNUA

Compound	Biological effects		Extent of methylation of DNA (μmol per mol DNA P)		
	Survival (%)	azg^r mutation frequency per 10^5 survivors)	7-methylguanine	3-methyladenine	O^6-methylguanine
DMS (8 μg ml^{-1})	82	10	48.1	8.8	ND
DMS (15 μg ml^{-1})	58	34	92.4	12.0	0.5
MNUA (30 μg ml^{-1})	81	148	50.3	5.4	7.5
MNUA (60 μg ml^{-1})	48	373	102.0	6.2	14.4

In these experiments, each 175 cm^2 plastic tissue culture flask (Nunc UK) was inoculated with 10^7 exponentially growing V79/4-K$_1$ cells in 50 ml DMEM. After incubation at 37 °C for 24 h, groups of five such cultures (about 2×10^8 cells) were treated either with ^{14}C-MNUA or ^{14}C-DMS (Radiochemical Centre, Amersham) of specific radioactivity 11 mCi mmol^{-1} and 18 mCi mmol^{-1} respectively. These doses were chosen to give approximately 80% or 50% survival (see Fig. 1). Immediately before treatment, stocks of the compounds were prepared at 250 times the required treatment concentration in DMSO which had been dried over Molecular Sieve (Fisons). Control cultures were treated with 0.2 ml DMSO alone. After 3 h exposure to the compounds the cells were detached from the flasks with trypsin/EDTA and samples taken for assay of survival and mutation frequency as described in the legend to Fig. 1. The remaining cells were washed twice in phosphate-buffered saline by centrifugation and resuspension. DNA was isolated from cell pellets by a modification of the method of Kirby[24]. Prior to chromatography, DNA samples were dissolved in 0.02 M phosphate buffer and hydrolysed in 0.1 M HCl at 70 °C for 30 min to liberate normal and methylated purine bases. The products of hydrolysis were chromatographed, together with marker alkylated bases, using a Waters ALC GPC 204 liquid chromatograph equipped with a Model U6K injector, a Model 440 ultraviolet detector (Waters Associates) and two columns (25 cm × 0.9 cm) of Partisil-10 SCX cation exchanger (Whatman) connected in series with a precolumn of the same material. Separation of methylated purine bases was achieved by elution for 40 min (4 ml min.$^{-1}$) with a gradient running from 0.02 M ammonium formate to 0.2 M ammonium formate, *p*H 4.0, in 8% (vol/vol) methanol[21]. Values for the extent of methylation at various DNA sites (expressed as μmol per mol DNA P) were calculated from the radioactivity associated with the respective peaks and the specific radioactivity of the methylating species. The amount of DNA analysed was calculated from the ultraviolet absorbance of column fractions containing adenine and guanine. The resolution of O^6-MeGua was improved if the fractions containing this base were pooled, rotary evaporated at *p*H 8.0 and rechromatographed on an ODS μ-Bondapak column eluted with a gradient running from 5% methanol: 95% 0.05 M ammonium formate (*p*H 4.6) to 55% methanol: 45% 0.05 M ammonium formate. ND = not detectable.

ribosyl transferase (HPRT; EC 2.4.2.8)[20]. These results will be reported fully elsewhere.

In order to investigate observed differences in mutagenic efficiency at the DNA level, the scale of experiments was increased to permit sufficient quantities of carcinogen-modified V79 cell DNA to be isolated and analysed. Cells were exposed to ^{14}C-MNUA and ^{14}C-DMS labelled in the methyl groups. Doses of each compound were chosen with the aim of reducing cell survival to either 80% or 50% of the control plating efficiency. After sampling cells for analysis of survival and mutation frequency, DNA was isolated, hydrolysed and methylated products separated by high-pressure liquid chromatography as described previously[21]. Table 1 summarises the results of typical experiments. At approximately equal levels of cytotoxicity the overall levels of DNA methylation were similar for DMS and MNUA and were proportional to the dose applied. Mutation frequencies (azg^r) at a given dose were typical of those found in the initial studies with unlabelled compounds. As expected[4], chromatography revealed three major methylated DNA products: 7-methylguanine (7-MeGua) 3-methyladenine (3-MeAde) and, in the case of MNUA, O^6-methylguanine (O^6-MeGua). With DMS, the latter product was detectable only with the more toxic treatment (15 μg ml^{-1}; 58% survival) and then was only present at one-thirtieth the level found with an equitoxic dose of MNUA. This was the only difference observed between the compounds which could explain their contrasting mutagenic potency. The ratios of the various products did not vary significantly from those previously reported for DNA which had been exposed to the same agents *in vitro* or *in vivo*[2,4,19].

A comparison of MNUA- and DMS-induced minor alkylation products, which were not readily detectable at the relatively low extents of methylation where mutagenesis could be measured accurately, was investigated by exposing calf thymus DNA (Sigma) *in vitro* to ^{14}C-labelled compounds. Quantities of highly methylated DNA were obtained from these experiments which permitted more sensitive analysis of alkylation products to be carried out. The results of the analysis are shown in Table 2. The relative proportions of the three major products (7-MeGua, 3-MeAde and O^6-MeGua) were similar to those determined in V79 cells (Table 1) which confirmed that the reaction of these agents with cellular DNA can be represented, both qualitatively and quantitatively, by such a model system. Moreover, with MNUA, there was again no evidence of any product other than O^6-MeGua which could account for its potent mutagenic activity.

We were not surprised by the lack of a perfect quantitative relationship between the extent of O^6-guanine methylation and the number of mutants induced by DMS and MNUA. Such a correlation would only be expected if, as seems unlikely, all methylation products other than the O^6-MeGua (that is the majority of DNA modifications) totally lacked mutagenic effect. Recent studies in this laboratory (J. R. Connell and A.S.C.M., unpublished results) indicate that most chromosomal aberrations induced in V79 cells by these agents are not due to O^6-MeGua, since similar numbers of aberrations are encountered at equivalent levels of total DNA methylation and cytotoxicity. Although gross damage of this type would not be expected to be particularly efficient at inducing viable azg^r and oua^r mutants in comparison with a miscoding base, it could make

Table 2 Extent of methylation of calf thymus DNA at various sites following treatment *in vitro* with ^{14}C-DMS and ^{14}C-MNUA

Compound	Methylated DNA products (% of total)							
	3-MeGua	7-MeGua	O^6-MeGua	1-MeAde	3-MeAde	7-MeAde	O^2-MeCyt	Apurinic acid
DMS (expt 1)	1.3	70.9	0.3	1.0	14.6	2.0	ND	9.8
DMS (expt 2)	1.2	74.5	0.4	1.1	15.2	1.5	ND	6.1
MNUA (expt 1)	1.0	70.0	7.7	0.7	8.0	0.8	0.1	12.0
MNUA (expt 2)	1.0	64.8	7.2	0.7	9.5	1.4	0.1	15.2

Solutions of calf thymus DNA (5 mg DNA ml^{-1}) in 0.02 M sodium cacodylate buffer (*p*H 6.9) were treated with ^{14}C-DMS (6 μCi ml^{-1}; 60 mCi mmol^{-1}) or ^{14}C-MNUA (1.8 μCi ml^{-1}; 11 mCi mmol^{-1}) for 1 h at 37 °C with frequent shaking. Immediately following treatment, the DNA was precipitated by the addition of 1/8 vol. 2.5 M sodium acetate and 1½ vols 2-ethoxyethanol. Hydrolysis and chromatography of the DNA were performed as described for Table 1. The values shown are the means of three separate determinations and the extent of methylation of various DNA sites is expressed as a percentage of total DNA methylation.

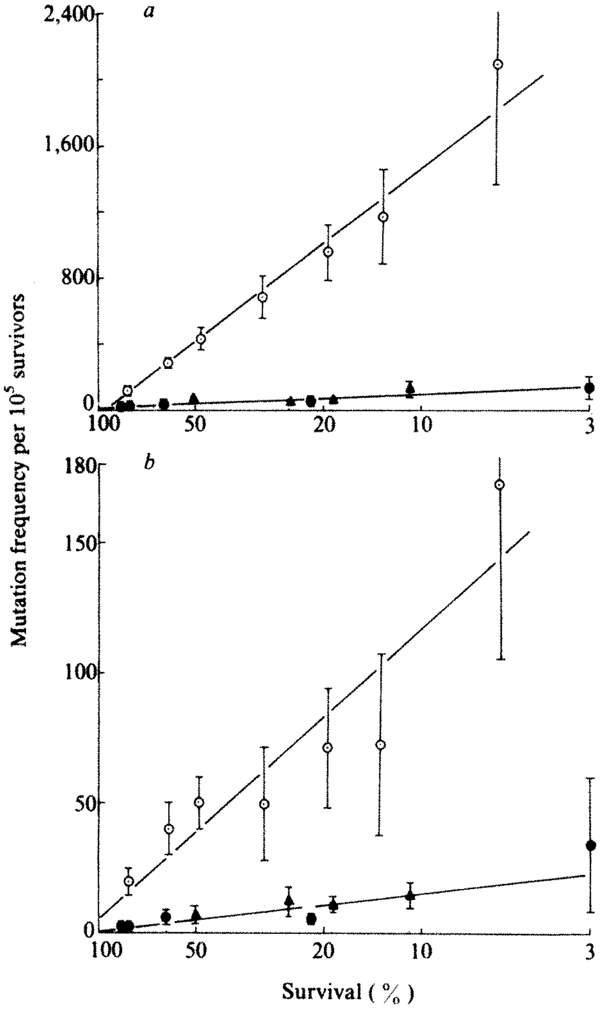

Fig. 1 Mutagenicity of DMS (●), MNUA (○) and MMS (▲) in V79/4-K_1 cells plotted as a function of percentage survival; *a*, azg^r, *b*, oua^r. The data, derived from several individual dose–response experiments, were expressed in this way to facilitate direct comparison between the agents in terms of their mutagenic potency per lethal event (mutagenic efficiency[14,18]). The advantages of this cell line for studies of mammalian cell mutagenesis have been discussed previously[11–14]. A clone of V79/4 designated V79/4-K_1, selected for its high plating efficiency and its ability to form diffuse microcolonies, was used throughout the course of this work. The latter characteristic allows the efficient recovery of mutants *in situ* which obviates the need to replate cells following each mutation expression period. In some experiments, both methods of selection were used and, invariably the highest mutant frequencies were observed with the *in situ* technique. In all experiments, 75 cm^2 plastic cell culture flasks (Nunc UK) containing 30 ml of Dulbecco's modified minimal essential medium (DMEM) with 10% fetal calf serum (Gibco) were each seeded with 2×10^6 cells grown from a clonal stock frozen in liquid nitrogen. After incubation at 37 °C for 24 h the resulting exponentially growing cultures were treated with various doses of the compounds added in 0.1 ml dry dimethylsulphoxide (DMSO). Control cultures were treated with 0.1 ml DMSO alone. After treatment at 37 °C for 3 h the cells were detached from each flask with trypsin-EDTA and the density of the resulting single-cell suspension estimated with a haemocytometer. For the determination of induced toxicity, 2×10^2 cells, and for mutation frequency, 5×10^4 cells, were plated in 5 cm and 9 cm plastic tissue culture dishes (Sterilin) respectively and incubated at 37 °C in a humidified atmosphere of 10% CO_2 : 90% air. Selection of azg^r (HPRT deficient) or oua^r (ATPase modified) mutants was effected by adding 8-azaguanine or ouabain to the plates such that the final concentration of the drug, in the medium, was 0.2 mM or 1 mM respectively. To achieve maximum recovery of mutants, a complete expression time curve was constructed for each dose of methylating agent. In practice, 5–10 replicates were treated with the selective agent at each of five expression time points ranging from 0–120 h after plating. Survival plates were stained after 7 d of incubation, mutation plates 3 d later, and colonies of more than about 50 cells, with observable mitotic figures, were scored. The plating efficiency of the cells was taken into account when calculating mutation frequencies. The values shown in the figure are derived from at least two separate experiments and are those obtained at peak expression times which ranged from about 48 h for minimally lethal doses to 96 h for the more toxic treatments. However, in all cases, maximum frequencies were observed after the cells had undergone an average of 4–5 divisions. Control frequencies did not exceed 4×10^{-5} per survivor. Standard deviations, indicated by bars attached to symbols, were calculated from the variance of the ratio of the mean numbers of colonies on mutation and survival plates; where bars are absent the standard deviation lies within the area of the symbol. Lines of best fit were obtained from DMS and MNUA data by least-squares linear regression analysis performed on individual mutation plate scores.

a major contribution to the overall mutagenicity of DMS or MMS which produce little O^6-MeGua. Indeed, there is evidence that, in bacteria, MMS is mutagenic by two distinct mechanisms, one of these dependent on the integrity of the *lexA*$^+$ (*exrA*$^+$)-mediated error-prone repair pathway[22]. Some insight into the mechanisms of alkylating agent mutagenesis in mammalian cells may be gained by detailed examination of the dose–response curves for mutation induction. The cumulative curves obtained in the present study for azg^r mutagenesis could imply the existence of two mutagenic mechanisms, one (presumably O^6-MeGua miscoding) predominating at low doses[23]. These curves can be described adequately by equations of the general form $M = aD + bD^2$ (M = azg^r mutation frequency per 10^5 survivors and D = dose in $\mu g\,ml^{-1}$) and for DMS and MNUA were calculated as $M = 1.30D + 0.13D^2$ and $M = 5.71D + 0.03D^2$ respectively. Interestingly, if we restrict our comparison of mutagenic activity to the linear terms of these equations (that is as D approaches 0) then the numbers of mutants calculated per μmol O^6-MeGua per mol DNA phosphorus (31 in the case of DMS and 24 for MNUA, extents of methylation estimated from data in Table 1) were very similar for the two agents.

Much remains to be understood about the relationship between specific DNA modifications and the various biological effects of the simple alkylating carcinogens. Nevertheless, the results described here strongly suggest that O^6-MeGua is responsible for the vast majority of gene mutations produced in mammalian cells by carcinogenic methylating agents. Moreover, the correlation between their mutagenicity in mammalian cells and their documented carcinogenic potency provides further support for the somatic mutation theory of cancer.

We thank Drs P. Brookes, and P. D. Lawley for their advice and Dr J. R. Connell for permission to quote her unpublished results. This work was supported by grants to the Institute of Cancer Research from the MRC and the Cancer Research Campaign and by NCI Contract N01-CP-33367.

Post-transcriptional control of coordinated ribosomal protein synthesis in *Escherichia coli*

Mats O. Olsson & Kirsten Gausing

Department of Molecular Biology and Plant Physiology, University of Aarhus, DK-8000 Århus C, Denmark

The synthesis of the approximately 50 different ribosomal proteins (r proteins) is very well coordinated[1] in *Escherichia coli*. As the r-protein genes are arranged in many different operons, placed at separate locations on the *E. coli* chromosome[2–5], it is not obvious how this coordination is maintained. The first indication that special controls are involved in the coordination came from the observations that merodiploid strains containing F′ factors with some of the ribosomal genes also synthesise the r proteins in balanced amounts[6,7]. The overall regulation of r-protein synthesis in response to changes in growth conditions is primarily mediated by changes in the rate of transcription of the r-protein genes[8]. To investigate whether the gene dosage control seen in merodiploid strains is also transcriptional in nature or whether other mechanisms are involved, we compared the transcription of r-protein mRNA in haploid and merodiploid strains. It was found that the rate of transcription of the r-protein mRNA from the *str–spc* cluster of genes changes in proportion to the gene dosage and it is concluded that the expression of r-protein genes is adjusted by post-transcriptional control.

About one half of the r-protein genes map in the *str–spc* region at 72 min on the *E. coli* chromosome and the genes are arranged in four separate transcriptional units[2]. All the r-protein genes in the *str–spc* region are present on the F′ factor KLF41 and most of the experiments were carried out with a pair of strains, with and without KLF41. Relative rates of synthesis and amounts of r-protein mRNA were measured using different types of hybridisation assays. As probes for different classes of mRNA DNA from the four transducing λ phages was used. λ*dfus*2 and λ*dspc*1 carry 27 (all) and 14 r-protein genes from the *str–spc* region, respectively[2]. As control for r-protein mRNA synthesis from genes not duplicated in the merodiploid strain, DNA from a transducing phage, λE3rp9, carrying r-protein genes from the 88-min region of the *E. coli* chromosome was used. The phage λE3rp9 was constructed *in vitro* and has the genes for L10, L11 and parts of the genes for L1 and L12 (K. G., in preparation). Nonspecific hybridisation was assayed with λ*dtrk* DNA. The phage λ*dtrk* is very similar to λ*dfus*2 and λ*dspc*1 but it does not carry any ribosomal genes[2].

For measurements of relative transcriptional activities of the r-protein genes, cultures were labelled in RNA for a period which was short relative to the half life of the unstable RNA fractions. The RNA was hybridised to excess DNA in conditions where the efficiency of hybridisation is better than 90% (Fig. 1). The relative rate of r-protein mRNA transcription from the *str–spc* region is nearly doubled in the F′-containing strain compared with the haploid strain whereas the L1–L12 protein mRNA is transcribed at similar rates in the two strains (Table 1). The gene dosage effect is the same for the complete and half of the *str–spc* region as *spc*-specific mRNA transcription is increased by the same factor as the *fus*-specific mRNA. The precise increase in the gene dosage in the KLF41-containing strain is not known. F′ factors are found in one or two copies per chromosome depending on the F′ factor and possibly the growth conditions[9]. The relative gene dosage (number of copies of gene *N* per genome equivalent) for the *str–spc* region on the chromosome is 1.15 calculated from the growth rate and the map position[10].

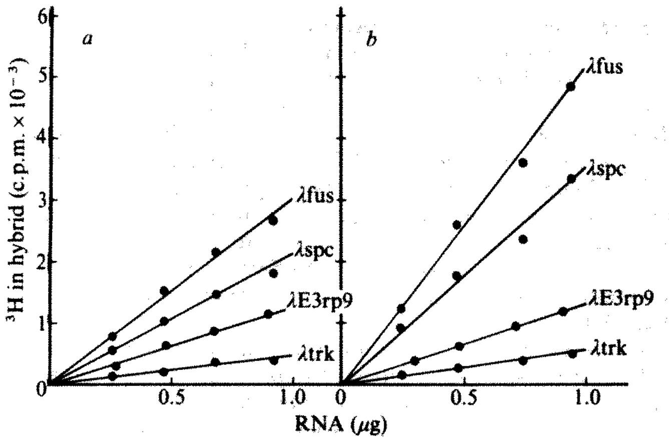

Fig. 1 Hybridisation analysis of pulse-labelled RNA from JC1553 and KLF41/JC1553. JC1553 (ref. 13) (*a*) and KLF41/JC1553 (ref. 14) (*b*) were obtained from N. Fiil. The two strains were grown exponentially at 37 °C in AB glucose minimal medium supplemented with a balanced mixture of 20 amino acids, the growth rates were 1.03 generations per h for JC1553 and 0.95 generations per h for KLF41/JC1553. At a density of 2×10^8 cells ml^{-1} the cultures were labelled for 45 s with [5, 6–^{3}H]uridine (40 μC ml^{-1} culture, specific activity 40 Ci mmol^{-1}) and the cells were collected on ice with Na-azide (10 mM). The RNA was extracted and hybridised to nitrocellulose filters with 10 μg of DNA from the transducing phages indicated as described previously[8]. Various amounts of RNA (0.25–1.0 μg) were hybridised and the values shown are averages of duplicate samples. The specific activity was 91,000 c.p.m. μg^{-1} for the JC1553 RNA and 88,000 c.p.m. μg^{-1} for the KLF41/JC1553 RNA.

The effect of changing the gene dosage for half of the r proteins in the *str–spc* region was measured by comparing the relative rates of transcription of r-protein mRNA in strains lysogenic for λ*dspc*1 and λ*dtrk*1. λ*dspc*1 contains two r-protein transcriptional units complete with the promoter regions (14 r-protein genes total)[2]. In the λ*dspc*1 lysogen the extra set of

Table 1 Relative rate of r-protein mRNA transcription

	% Of total radioactivity			Diploid/haploid		
Strain	L1–L12 mRNA	*spc* mRNA	*fus* mRNA	L1–L12 mRNA	*spc* mRNA	*fus* mRNA
JC1553	0.79	1.66	2.58			
KLF41/JC1553	0.73	2.92	4.57	0.9	1.8	1.8
NO1294 (λ*dtrk*)	0.51	1.36	2.36			
NO1267 (λ*dspc*1)	0.48	2.10	3.14	0.9	1.5	1.3

The per cent of the radioactivity in pulse-labelled RNA from JC1553 and KLF41/JC1553 that hybridises to four different types of DNA was calculated from the slopes of the curves in Fig. 1. Subtraction of the per cent radioactivity in λ*dtrk* DNA hybrid yields per cent radioactivity specific for the r-protein genes on λE3rp9 (genes for part of L1, L11, L10, and part of L12), λ*dspc*1 (14 r-protein genes) and on λ*dfus*2 (27 r-protein genes). NO1294 and NO1267 (from R. Jaskunas) are strains lysogenic for λ*dtrk* and λ*dspc*1. These strains were grown at 30 °C in AB glucose minimal medium; the growth rates were 0.78 generations per h for NO1294 and 0.74 generations per h for NO1267. RNA was labelled and analysed as described in Fig. 1 and results were evaluated as the results for JC1553 and KLF41/JC1553.

0028-0836/80/060599—02$01.00

r-protein genes is probably located at λ*att* at 11 min on the *E. coli* chromosome, in which case the gene dosage of the *spc* genes in the λ*dspc*1 lysogen is 1.7 relative to that in the λ*dtrk* lysogen. The increase in the relative rate of transcription from the duplicated genes is 1.5 (Table 1), which is seen directly from the *spc* mRNA results. The *fus* mRNA results are compatible with a 1.5-fold increase in the rate of transcription from the genes in the *str–spc* region that are duplicated in the λ*dspc*1 lysogen and identical rates of transcription from the genes that are not duplicated. A similar gene dosage effect on the rate of transcription of r-protein mRNA has been reported for a related λ*dspc*1 lysogen[11].

The JC1553 pair of strains differ from the pair of lysogens not only with respect to the mode of duplication of the *r*-protein genes. JC1553 is *recA* which is reflected in the relative low growth rate (see Fig. 1 legend), whereas the lysogens are *recA*$^+$. However, analysis of both sets of strains leads to the conclusion that the rate of transcription of the genes in the *str–spc* region is nearly proportional to the gene dosage. As the rate of synthesis of the r proteins in the merodiploid cells is well coordinated and identical to the rate of synthesis in the haploid cells[6,7,11], it follows that the yield of peptides per round of transcription is reduced specifically for the mRNA from the duplicated genes.

We then asked if this decrease in translation efficiency is reflected in the stability of these mRNAs. When the relative rate of transcription of a class of mRNA is known the average physical half life can be deduced from estimates of the amounts of mRNA. The relative amounts of r-protein mRNA were therefore determined in JC1553 and KLF41/JC1553. In one experiment the two strains were labelled uniformly in RNA and the per cent radioactivity in different classes of r-protein mRNA was measured by hybridisation to excess DNA. Table 2 shows that the merodiploid strain contains elevated levels of mRNA from the duplicated regions but the genes dosage effect is not as pronounced as for the rates of transcription of these mRNA species (Table 1). In another experiment pulse-labelled RNA was hybridised to limiting amounts of DNA. When DNA–RNA hybridisation approaches saturation a linear curve is obtained in a reciprocal plot (Fig. 2) and it has been shown that the amount of DNA-specific RNA is inversely proportional to the slope of the line[12]. Also this experiment shows that a duplication of r-protein genes is accompanied by a significant increase in the amount of the corresponding r-protein mRNA. A smaller increase (20%) in the amount of *spc* mRNA was seen in a strain lysogenic for a λ*dspc* phage[11], which probably reflects that the increase in r-protein gene dosage is smaller in the lysogen than in the KLF41-containing strain.

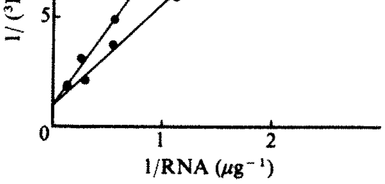

Fig. 2 Relative amounts of r-protein mRNA determined by hybridisation to limiting amounts of DNA. Different amounts of pulse-labelled RNA (0.4–7.0 μg) from JC1553 and KLF41/JC1553 (the same samples as used in Fig. 1) were hybridised to nitrocellulose filters with 0.5 μg λ*dtrk* DNA and 0.5 μg λ*dfus* DNA. Values on the ordinate represent c.p.m. hybridised to λ*dfus*2 DNA corrected for c.p.m. hybridised to λ*dtrk* DNA. The reciprocal of the slope for KLF41/JC1553 is 1.6 × the reciprocal of the slope for JC1553.

Table 2 Amounts of r-protein mRNA

Strain	JC1553	KLF41/JC1553
Total c.p.m.	154,000	158,000
c.p.m. In hybrid:		
λ*dtrk* DNA	510	575
λE3rp9 DNA	637	685
λ*dspc*1 DNA	858	1,098
λ*dfus*2 DNA	1,259	1,591
% In mRNA:		
L1–L12	0.08	0.07
spc	0.23	0.33
fus	0.49	0.64
Diploid/haploid:		
L1–L12 mRNA	0.9	
spc mRNA	1.44	
fus mRNA	1.31	
fus mRNA	1.6 (from Fig. 2)	

JC1553 and KLF41/JC1553 were grown exponentially at 37 °C in MOPS minimal medium with low phosphate (0.2 mM). The growth rate was 0.76 generations per h for JC1553 and 0.73 for KLF41/JC1553. At a density of about 6×10^6 cells ml^{-1} ^{32}P was added to the cultures (10 μC ml^{-1}) and 5 generations later (at 2×10^8 cells ml^{-1}) the cells were collected. RNA was extracted and duplicate portions of 0.5 μg and 1.0 μg were hybridised to nitrocellulose filters with 10 μg DNA. The c.p.m. in hybrid listed represent average values.

As the rate of transcription of the *str–spc* mRNA is increased more than the amount of the *str–spc* mRNA in the merodiploid strain, it follows that the average physical half life of the mRNA from the duplicated r-protein genes is somewhat shorter than in the haploid strain. However, the merodiploid strain does contain an excess of mRNA sequences from the duplicated r-protein genes.

In conclusion we have found that the rate of transcription from the r-protein genes in the *str–spc* region increases in proportion to the gene dosage when extra copies of these genes are supplied by an F′ factor or a transducing λ phage. As the rate of synthesis of the r proteins is unaffected by such changes in gene dosage[6,7] it shows that post-transcriptional controls adjust the rate of r-protein synthesis.

On the basis of similar observations it was recently proposed that the post-transcriptional control acts by inactivation and degradation of the excess of r-protein mRNA[11]. The results available so far are, however, equally compatible with mechanisms that involve blockage of translation of intrinsically active r-protein mRNAs. The increased lability of overproduced mRNAs could then be the consequence rather than the cause of their lower degree of participation in protein synthesis. The precise coordination of r-protein synthesis in normal cells, coupled with the recent observations that the r-protein gene clusters are spread over most of the chromosome[2–5], suggests that post-transcriptional control may be evolved in normal cells in order to compensate for the successive replication of the different r-protein genes during the cell cycle.

MATTERS ARISING

Hybridisation of scDNA does not lead to overestimates of mRNA complexity

THE contention of Kiper[1], that complexity estimates of mRNA populations measured by hybridisation with single copy DNA (scDNA) are routinely overestimates, is not supported by previously published data and additional data we provide here. Kiper argues that selective loss of single copy sequences (cryptic unique sequences) occurs when scDNA is isolated from randomly sheared DNA because they are adjacent to repetitive sequences. He contends that the loss is selective for sequences which do not code for messenger RNA, and hence scDNA is enriched in sequences which code for mRNA. Thus complexity measurements on mRNA based on scDNA hybridisation result in overestimates.

From data on the sea urchin genome[2] it can be calculated that ~19% of the total genomic DNA might be present as 'cryptic' scDNA when 450-nucleotide fragments are used in the preparation of scDNA. Assuming all of the cryptic scDNA to be non-code sequence, the resulting scDNA would be enriched for code sequences such that saturation hybridisation data might yield a complexity estimate that is too high by a factor of ~1.3, which is less than suggested by Kiper. A more important consideration is the likelihood that code sequences are extensively represented in cryptic scDNA. For example 80–100% of the mass of the mRNA in sea urchin embryos is complementary to scDNA sequences which are adjacent to interspersed repetitive sequences[3]. If this is also true for complexity, and if the sequence organisation of sea urchin DNA is typical of eukaryotic genomes, then cryptic scDNA would contain code sequences and may even be somewhat enriched for these sequences. Whatever the case, a portion of the cryptic scDNA is expected to be code sequences. We have also found, using S_1 nuclease, that only about 10% of mouse DNA considered to be repetitive by hydroxyapatite (HAP) analysis of renaturation kinetics may be cryptic scDNA. Thus the extent of code sequence enrichment of scDNA suggested by Kiper seems unlikely.

Kiper's second point, that assay of DNA/RNA hybrids by HAP chromatography leads to overestimates due to the non-base-paired intervening sequence being present in DNA/RNA hybrids, is an important consideration in light of recent studies which suggest that several known structural genes are discontinuous in the genome[4–6], and perhaps, as well, a large number of unidentified mRNA coding sequences[7]. However, values obtained by HAP and S_1 nuclease assays of hybridised scDNA are similar (Table 1). It is evident from this comparison that a negligible portion of the hybridised scDNA is not base paired, as has been previously reported[8]. Despite these results we concur that S_1 nuclease method of assay is preferable to the use of HAP for reasons presented elsewhere[9].

From the aspects mentioned above Kiper suggests that the discrepancy between the scDNA and the cDNA methods of estimating the complexity of mRNA populations is largely due to gross overestimates generated by the scDNA method. From our results we find the discrepancy to be due more to the inaccuracy of the $C_0t\frac{1}{2}$ determinations for the most complex class of mRNA which is particularly imprecise if the cDNA is only partially hybridisable (that is, ~75% or less). We prepared cDNA complementary to mouse brain poly(A)$^+$mRNA which was hybridisable to 91–92% S_1 resistance. From hybridisation kinetics the complexity of the poly(A)$^+$mRNA was estimated to be 1.1×10^5 kilobases[10], a value which is similar to that obtained by the scDNA hybridisation method (Table 1). We conclude that the scDNA hybridisation method does not lead to gross overestimates of the complexity of RNA populations for reasons offered by Kiper.

HYBRIDISATION of labelled single copy DNA with an excess of RNA is an important procedure for estimating the number of genes expressed in cells[1]. Recently, Kiper[2] asserted that gene number values in plants obtained by using this method are routinely significant overestimates. To support his premise, Kiper cited our measurements of the number of genes expressed in the tobacco leaf[3]. We contend that our original interpretation of the tobacco data[3] is theoretically sound and that the re-interpretation by Kiper[2] is based on specious arguments.

Kiper's first argument maintained that a large fraction of interspersed single copy DNA (scDNA) in plant genomes consisted of $\leq$300-base pair, unexpressed sequences. During the kinetic isolation of scDNA, these short, interspersed, unique sequences would be selectively lost due to their close linkage with repetitive sequence elements. The effective result (as Kiper maintains), therefore, would be an enrichment for expressed sequences in the single copy preparations used for DNA/RNA hybridisation experiments. Most plant genomes investigated to date, however, do not possess very short interspersed single copy sequences[4]. For example, the vast majority of interspersed single copy sequences in tobacco[5], soybean[6–8], cotton[9], corn (S. Hake and V. Walbot, unpublished), wheat[10], and mungbean[11] exceed 1,000 base pairs. Only in pea[12] and perhaps rye[13] does there seem to be a fraction of short scDNA. Direct electron microscopic observations have shown that the minimum number average lengths of interspersed single copy sequences in soybean[7] and cotton[9] are 1,300 and 2,900 base pairs respectively. Few short (<500 base pairs) single copy sequences were visualised (<5%). As the fragment length (200–300 bases) of scDNA used in gene expression studies is much less than that of the interspersed unique DNA, it is unlikely that a separate complexity class of unexpressed, 'cryptic', single copy sequences will be removed during scDNA isolation. The scDNA mass that is lost (due to short period interspersion effects) will simply be that which is at the termini of moderately long scDNA regions. Such regions have been demonstrated to code for mRNA[14–16]. We argue, therefore, that short plant scDNA preparations of the type used in RNA-excess/scDNA hybridisation experiments will not be enriched for expressed sequences or any other sequences as Kiper asserts.

Kiper's second argument was based on recent observations which have demonstrated that several animal genes are interrupted by non-coding sequences (intervening sequences)[17]. He contends, correctly, that if intervening sequences are present in plant genomes, they could potentially lead to an overestimate of gene number when DNA/RNA hybrids are assayed by binding to hydroxyapatite. However, as shown in Table 2 this is not the case, as similar gene number values were obtained with the scDNA method

0028-0836/80/060601—03$01.00

Table 1 Complexity of RNA from mouse brain assayed by HAP or S_1 nuclease

RNA	Method of assay*	scDNA as hybrid (%)	Complexity‡ (kilobases)
Poly(A)$^+$mRNA, brain	S_1 nuclease	3.9	1.25×10^5
Poly(A)$^+$mRNA, brain	HAP	4.1	1.33×10^5
Poly(A)$^+$mRNA, brain	HAP	3.6†	1.17×10^5
Nuclear, brain	S_1 nuclease	18	5.85×10^5
Nuclear, brain	HAP	19	6.17×10^5
Nuclear, brain	HAP	19.9†	6.46×10^5

* Assays were as previously described[8,9] with slight modifications.

† Previously reported value[8].

‡ Complexity estimate calculated on the basis that the single copy fraction of the mouse haploid genome is 3.25×10^9 nucleotides.

using both S_1 nuclease (which would eliminate non-coding sequence effects) and HAP assays. These data demonstrate that the presence or absence of intervening sequences has an insignificant effect on gene number values obtained by using HAP analysis with short single copy tracers.

In support of his arguments Kiper compared values obtained from mRNA/cDNA hybridisation studies[18] with those derived from RNA/single copy analysis[1]. In the case of our data[3] Kiper noted 'strikingly different' estimates of the number of genes expressed in the tobacco leaf from the two procedures (12,000 against 27,000). In our original report we discussed the inaccuracies inherent in gene number values derived from cDNA hybridisation. We stated explicitly that the data were consistent with a range of 6,000 to 24,000 diverse gene transcripts (see Fig. 3 and Table 1 of Ref. 3) and were thus consistent with the value obtained from the single copy procedure (see Fig. 4 and Table 2 of Ref. 3). As we and others[19–22] have discussed, computer solutions of cDNA hybridisation results must be interpreted with circumspection. In the absence of other information (for example, hybridisation analysis of isolated rare message cDNA), the gene number values computed cannot be considered unique and are accurate to only within a factor of 2.

Even if there are only 12,000 diverse gene transcripts represented in the tobacco leaf poly(A)$^+$mRNA population, this value would still be compatible with 27,000 gene transcripts in total mRNA. Approximately 50–70% of leaf mRNA is non-adenylated[3,23]. Several laboratories[24–26] have demonstrated that poly(A)$^+$ and poly(A$^-$) mRNAs may contain distinct subsets of gene transcripts. For example, there are about 120,000 diverse gene transcripts present in the poly(A$^+$) mRNA of mouse brain cells compared with 220,000 in total mRNA[24,27]. Thus, a comparison of cDNA hybridisation data with scDNA hybridisation data cannot be used to support Kiper's contention that the latter method overestimates gene number.

Finally, we wish to point out that gene number values, as estimated by any procedure, cannot be considered absolute. They are limited by many factors, including the presence of undetectable rare mRNAs (<0.1 molecule per cell), the use of abundant mRNA sizes to calculate gene numbers[28], salt correction factors used in kinetic analysis (W.E.H. unpublished) and the precision in measuring very small proportions of hybridised DNA. At the present, however, single copy measurements produce the most precise and reliable estimates of gene numbers, even in higher plants.

KIPER REPLIES—The first point stressed in my recent paper[1] was that in eukaryotic single copy DNA prepared for mRNA complexity measurements short unique sequences are absent and ends of longer unique sequences are under-represented while long unique DNA sequences will be over-represented. This is caused by sequence interspersion of different kinetic classes and random shearing. Thus taking the total nuclear unique DNA content as a basis for complexity calculations, gene number overestimates result if mRNAs are preferentially encoded for by longer unique sequences.

Concerning the sea urchin mRNA complexity measurements, the degree of over-representation could indeed be 1.5 as could the gene number overestimate: so, at a length of 450-nucleotide reassociation kinetics displayed a 50% unique DNA content[2]. Galau *et al.*, however, took a 75% content as the basis for their estimates[3], a value derived from the fraction of S_1-digestible C_0t 20 reassociated DNA[2].

The point questioned by Goldberg and Timberlake is whether genomes (especially of the plant kingdom) will contain gross amounts of short cryptic unique DNA. This, now, is certainly proved for pea DNA. Murray *et al.* demonstrated that the major class of single-copy sequences has a modal length of about 300 nucleotides (ref. 4) and that due to the intimate interspersion with repetitive DNA no true single copy tracer can be prepared[5]. Goldberg and Timberlake's contention is that in tobacco (and other plants) very few unique sequences are shorter than 500 base pairs and the average length of interspersed scDNA sequences is at least 1,400 nucleotides. Hence the scDNA preparation is a fair representation of the total scDNA complexity, cryptic DNA thus becoming negligible. Their data, however, seem to conflict with this view: so, in HAP renaturation kinetics analysis of a fragment length of 300 nucleotides 22–23% of the whole genome was included in the unique DNA fraction. This increased to 43% using S_1 nuclease (47% after some minor correction)[6]. Their mRNA complexity measurements were based on the complexity of a 42.5% scDNA fraction[7]. Now think of a population of interspersed unique DNA sequences averaging 1,400 nucleotides; then during reassociation analysis of sheared 300-nucleotide-long whole genomic DNA, 81% of this would be scored as unique DNA using HAP analysis (for formulae see ref. 1): that is a

Table 2 Estimates of gene number derived from the single copy procedure using hydroxyapatite and S_1 nuclease assays

Organism	Assay		Ref.
	HAP	S_1 nuclease	
Tobacco	27,000	24,000	3*
Achlya	2,000	3,200	29, 30
Mouse brain	100,000	120,000	24, 27

*J.C. Kamalay and R.B.G., unpublished.

23% increase would be expected, revealing the whole unique DNA content using S_1 nuclease. The 87% increase found in tobacco (taking the corrected value of 47% instead of 43% this amounts to a more than 100% increase) seems rational only at an average unique DNA fragment length of less than 600 nucleotides. As many sequences seem to be longer than 1,000 nucleotides this favours a broad class of rather short unique sequences behaving cryptically. Only if all these unique sequences—whether short, medium or long—code for mRNA to the same extent would it be valid to base gene number estimates of tobacco and other organisms on the total nuclear unique DNA complexity. However, this is unlikely considering what is now known about mRNA length and organisation of individual genes.

Hahn *et al.* argue that coding sequences are extensively represented in a repetitive sequence neighbouring unique DNA, which is, as I pointed out, under-represented in scDNA preparations; nevertheless it would still be valid to refer to the total unique DNA complexity. In support of this they cite the sea urchin experiment of Davidson *et al.*[8]. However, the mRNA mass–complexity equivalent postulated for this experiment is not backed by any results. In that experiment 77% of the mass of all mRNA seemed to be adjacent to interspersed repetitive sequences; but, as only a total of 8 ± 4% of all mRNA mass represented almost the whole complexity[3], the results can equally be interpreted as meaning that only a few (abundant) mRNAs were adjacent to repetitive DNA. Furthermore, the HAP assay was used, and in view of recent insights into gene interruption this technique could have measured minor coding portions of genes adjacent to repetitive elements. The main argument, however, is that the last fractionation in purification of the repeat contiguous DNA excluded all unique DNA behaving cryptically in reassociation kinetics from the pool which was allowed to hybridise with the mRNA population. Therefore, this experiment is irrelevant to the question.

The finding of Hahn *et al.* that in mouse only 10% of HAP-assayed repetitive DNA is digested by S_1 nuclease is in contrast with other findings, for example, in the sea urchin[2] and tobacco[6] where 50% and 43%, respectively were digestible. Thus the mouse experiments do not seem to be representative and favour minimal interspersion between different kinetic classes in the mouse genome.

Concerning intervening sequences—the second point of my paper—their general occurrence will have to be deduced by further research. A close look at the organisation of individual genes, as carried out for the globin genes[9] or the ovalbumin gene[10] and the ovomucoid gene[11] and lysozyme[12], has revealed the existence of rather short gene domains separated by intervening sequences of about equal length or longer. If the intervening sequences are unique in the genome too, as shown for the globin[13] and the ovalbumin gene[14], that is if genes are located in long stretches of unique DNA, a large fraction of the introns will be scored as coding complexity in the scDNA saturation experiments described. Only if the length of the scDNA preparation is much smaller than the exons would interference by intervening sequences be unimportant. However, most of the coding domains known today are even shorter than the scDNA preparations routinely used in complexity measurements[9–12]. The data compiled by Goldberg, Timberlake, Hahn and coworkers in their critiques seem to contradict the argument. Apparently, however, to solve the problem it will be necessary to check HAP-isolated hybrids for their content of non-coding single-stranded DNA loops.

Previous interspersion analysis of many genomes has demonstrated that sea urchin DNA organisation is not typical of eukaryotic genomes as postulated by Hahn *et al.*; nor is any other sequence organisation pattern. Eukaryotic genomes differ largely in their content of repetitive DNA and their interspersion patterns. Long period interspersion of unique DNA was found to be predominant in birds[15], fungi[16] and insects[17]. Higher plants show varying interspersion patterns with unique DNA lengths of 300 nucleotides being predominant in pea[5] while *Xenopus*-like patterns are predominant in tobacco[6]. Short unique sequences can be separated by short repetitive sequences (300–400-nucleotide fragments in pea[6]), repetitive sequences 1,250 base pairs long (as in cotton[18]) or by repetitive sequences thousands of base pairs long, as in the genome of pearl millet[19]. Higher plants with low haploid genome size contain half of their scDNA in stretches a few thousand base pairs long[19,20]. Most other plant and animal genomes also contain long unique DNA sequences. So, the question remains whether coding sequences are typically located within long stretches of unique DNA.

However, genome and gene organisation complicate interpretation of DNA saturation experiments. Furthermore, many considerations lead to the conclusion that scDNA saturation experiments will routinely overestimate numbers of active genes: over-representation of coding sequences in the unique DNA preparation, split genes, few-copy DNA taken for scDNA, gene duplication as in the human globin genes, cross hybridisation of certain gene domains[21], and scoring of unique gene flanking sequences as coding. So, many detailed answers have to be given before the results can be interpreted with confidence. This will be a more severe problem with genomes containing large amounts of repetitive DNA and extensive interspersion with unique DNA, as is typical in higher plants.

Aminostratigraphy of Pleistocene and Holocene deposits

RECENT work on amino acid ratios for sites in the UK is a major step forward in the research of the Pleistocene and early Holocene periods[1,2]. Archaeological work, coupled with environmental studies, can be valuable in supporting amino acid research or in pinpointing possible discrepancies and problems. Miller *et al.*[1] have compared the Purfleet and Swanscombe Pleistocene sites, pointing out that the mean D-alloisoleucene: L-isoleucene ratio for Purfleet is 0.35 while for Swanscombe the ratio is 0.30. At Purfleet, as at Swanscombe, there are three main gravels separated by sands and silts, and the artefacts from Purfleet are comparable with those of the Middle Gravels from Swanscombe[3]. The shell samples used from

0028-0836/80/060603—02$01.00

Swanscombe came from the Middle Gravels but those from Purfleet came from a shell band which is ~1 m or more below the main or Middle Gravel at that site, immediately above a coarse sandy orange-brown gravel, referred to as Gravel 3. Very few artefacts came from this Lower Gravel, but some of Clactonian aspects were present. It can, therefore, be suggested that the whole series of deposits at Purfleet are comparable to those at Swanscombe. As the amino acid ratios from Purfleet refer to deposits which are stratigraphically somewhat older than the Middle Gravel at Swanscombe, the discrepancies in the ratios can possibly be explained on this basis as dating slightly different phases of the same interglacial.

Andrews, Bowen and Kidson[2] pointed out that the Portland Raised Beach and Burtle Beds have produced ratios which do not agree exactly with those of Middle Hope and Minchin Hole, all frequently assigned to the last interglacial. There may be several explanations for these discrepancies. Attention has often been drawn to the fact that there are pronounced altimetric differences between the Beach deposits in various parts of the Bill area of Portland, and it has recently been pointed out that there may be at least two quite distinct raised beaches on the Isle[4]. Here again, different phases of the same interglacial may be involved, indicating minor advances and regressions of the sea.

On the other hand, other environmental factors could possibly be involved, as suggested by the ratios of the Holocene sample from Portland. This sample came from the Mesolithic habitation site of Culver Well, with a very large shell-midden with uncalibrated radiocarbon dates of 5200±135 BC (BM-473) and 5151±97 BC (BM-960); a weighted average of three samples of burnt limestone from a hearth has given a thermoluminescence date of 5400 BC±640 (OxTL 501 b, m)[5]. The stratigraphical evidence and archaeological finds from the midden clearly indicate a dating within the Mesolithic period, falling within the Atlantic climatic zone. The other Holocene sample came from Skara Brae in the Orkneys, a site known from the archaeological evidence to belong to the late Neolithic period associated with pottery of the Rinyo type, that is this site is at least 3,000 yr younger than Portland (or less than half the age of the Mesolithic site). Yet both sites have produced D-allo: L-iso (combined) ratios of 0.04, indicating that results from one or the other, or perhaps even both, the Holocene control samples are unreliable. This too could possibly be explained by different environmental or economic circumstances relating to the sites, during the relevant prehistoric periods and after, affecting the epimerisation reaction of the samples. Or it may be that the sensitivities of the techniques are not yet so advanced that differences of only a few thousand years can be registered.

These discrepancies do not, however, minimise the great value of the work being done on amino acid reactions as potential chronological indices.

4. Coombe, E. D. K. thesis, Oxford Univ. (undated).
5. Palmer, S. *Proc. prehist. Soc.* **42**, 324–327 (1976).

MILLER *ET AL.* REPLY—Our *Corbicula* from Swanscombe are not from, but merely correlated with, the Middle Gravels there. If the correlation is correct, then the absence of *Corbicula* in the Swanscombe Lower Loam and Lower Gravel, at an elevation intermediate between the Middle Gravels and Grays (with similar ratios), suggests that the Lower Loam and Lower Gravel may be from an older interglacial. The *Corbicula* at Purfleet could be from early in the Middle Gravels interglacial, or from another interglacial, intermediate in age between the Middle Gravels and Lower Loam–Lower Gravel ones.

At current temperatures in Britain, amino acid epimerisation occurs slowly; hence, as Palmer infers, we cannot detect as yet differences of a few thousands of years. This does not mean that such discrimination is not possible. Instrumentation is improving rapidly, and there are several different reactions that may give the resolution required.

Ours[1,2] are preliminary analyses: our papers have demonstrated that amino stratigraphy will provide a useful time-frame for UK Pleistocene studies. To that end, we would like to say that we are very willing to cooperate with UK researchers on problems where this technique may be applicable.

Asymmetry in relatedness: who is related to whom?

FLESNESS[1] has brought out the interesting fact that relatedness between diploids can be asymmetric, as it is between the sexes of male-haploids[2]. His note, however, contains a conceptual difficulty. This concerns the directionality of relatedness in his otherwise valuable definition. Because relatedness calculations are usually made in order to determine the (theoretical) optimum course of action of a potential altruist *vis-à-vis* a particular recipient, we suggest that the quantity implied in the phrasing 'relatedness of recipient to donor' should be the genetic similarity of the recipient to the donor, but under Flesness's definition it is the genetic similarity of the donor to the recipient. If weighing up (in terms of relationship) the benefits of being altruistic towards someone, you should care about the proportion of your genes that is present in him, and not the portion of his genes present in you. We therefore redefine Flesness's coefficient:

$$R_{B(A)} = \text{relatedness of B to A}$$

$$= \frac{\text{(mean identity by descent of A's genes with B's gametes)}}{\text{(mean identity by descent of A's genes with A's gametes)}}$$

This directionality is also the same as that adopted by Hamilton[3] in discussing essentially the same parameter. As a consequence, the values given in Flesness's table should be reversed.

$R_{B(A)}$ (as defined above) has the same meaning as the 'pedigree coefficient of relatedness', $G_{B(A)}$ (ref. 2, and R. Frankham, in preparation), and is also similar to the 'regression coefficient of relatedness', $b_{B(A)}$ (ref. 3) (with the subscript order reversed here to conform with standard regression notation). We suggest that $G_{B(A)}$ be retained for use as the central measurement of relatedness in pedigrees (as $R_{B(A)}$ is more easily confused with Wright's[4] 'coefficient of relationship', r), and that Hamilton's coefficient be retained for estimates of relatedness derived by regression analysis of populations (P.P. and R.H.C., in preparation).

We thank W. D. Hamilton for comments on an earlier draft of the manuscript. P.P.'s stay in Australia was supported by the Australian Education Department under the Australian/European Scheme; R.H.C.'s research is supported by grants from the Australian Research Grants Committee and the Ian Potter Foundation.

Enigmatic variations

A.B. Pittock

Sun, Weather, and Climate. By J.R. Herman and R.A. Goldberg. Pp.360. (National Aeronautics and Space Administration: Washington, DC, 1979.)

THIS well produced paperback addresses the question as to what influence solar variations have on weather and climate. This is a highly controversial and (as I know from personal experience) an emotional subject.

So let me, at the outset, lay my own established position on the line. Quoting from my published review "... it seems that despite a massive literature on the subject, there is at present little or no convincing evidence of statistically significant or practically useful correlations between sunspot cycles and the weather or climate." (*Rev. Geophys. Space Phys.*, **16**, 400; 1978). At the time I wrote that (late 1977), swayed particularly by the critical examination by C.O. Hines and I. Halevy (*J. atmos. Sci.*, **34**, 382; 1977) of the work of J.M. Wilcox *et al* (*J. atmos. Sci.*, **33**,1113; 1976), I conceded that there were "... apparently significant short-term correlations between meteorological indices and the passage of solar magnetic sector boundaries. . .". Now that I have read R.G. Williams and E.J. Gerety (*Nature*, **275**, 200; 1978) and R. Shapiro (*J. atmos. Sci.*, **36**, 1105; 1979) on that particular subject I am not so convinced by the short-period effects either.

Contrast these rather negative comments with the more positive upbeat approach and conclusions of Herman and Goldberg. In the preface (page v) we read: "Even though the reported results have sometimes been confused, disjointed, and contradictory, there has emerged a growing belief that there are connections between changes on the Sun and changes in the lower atmosphere". In the penultimate chapter (page 274) entitled "Recapitulation of Sun-Weather Relationships" we read that "In summary, the correlations between solar activity and meterological responses are highly suggestive and require further investigation. To take an agnostic point of view, these relationships have not been proven or disproven and therefore require further attention.".

What accounts for this apparently profound difference in our assessments of essentially the same evidence? I wish the philosophers of science would address themselves to this particular controversy because I suspect that in the literature on the solar weather/climate relationships they will find their best possible case study of objectivity versus subjectivity, and of the conscious or unconscious influence of vested interests and disciplinary prejudices. It is for instance almost axiomatic in this controversy that meterologists and climatologists will applaud my 'critical' approach, while ionospheric and solar physicists will prefer Herman and Goldberg's more optimistic or 'agnostic' approach.

The cynics will put this down to blatant self-interest, each group seeking to justify its own research interests and even secure funding for its more expensive projects. But I believe it runs deeper and is more subtle than that. Whatever the motivation, the disbelievers and skeptics demand a degree of statistical rigour and level of proof which the believers feel to be unnecessary or destructive of a potentially important physical and practical insight into nature. The protagonists can point to the well established proven influence of solar variations on the ionosphere and mesosphere and suggest that such influence must extend down into the meteorologically active regions. The presumption is that such effects exist in the lower atmosphere and the problem lies in establishing the magnitude and precise nature and mechanisms of such effects.

What we are seeing in this controversy is thus a reversal of the onus of proof or of the null hypothesis from that which is usual in science. The protagonists wish to use as their null hypothesis the proposition that solar effects do exist, and are thus satisfied (at least for now) with a situation in which this has not been disproven beyond reasonable doubt. The opposite null hypothesis, that no effect exists until it is proven to exist beyond a reasonable doubt is the traditional hypothesis which safeguards the purity of established scientific theory. In the present state of the solar weather/climate controversy these two positions are poles apart in terms of the level of proof or rigour applied to the available data.

To take a couple of specific (if perhaps extreme) examples from Herman and Goldberg's book, let us look at their treatment of two of the more spectacular and well known claims of a significant effect of solar cycles on climate.

Herman and Goldberg report concerning thunderstorm frequency (page 142) "The strongest correlation [with sunspot numbers] (about + 0.9) is found in Siberia and has been consistently reported as such for many years (Septer, 1926; Shaw, 1928; Brooks, 1934). Likhter reported the same value again in 1968 (Markson, 1971)." [*Pure Appl. Geophys.*, **84**, 161; 1971]. They then go on to discuss these results, stating that the "original work on Siberian thunderstorms was apparently done by Septer" and noting that Brooks used Septer's data, but not making clear that Shaw also used Septer's data and that Likhter *et al.* did not find such a strong relationship using more recent data. Markson's reference to Likhter *et al.* (1968) is to an unpublished conference paper, but a paper with the same authors and title is Likhter, Ia.I, Kolokolov, V.P. and Kleimenova, E.P.; *Trudy, Glavnaia Geofiz. Abs.* No.242, 104; 1969. They used IGY–IQSY data and found a more "complex relationship" than that reported by Brooks. Instead of four independent and consistent results we thus have only one, which is not so impressive. Herman and Goldberg compound this inflated impression of Septer's results by failing to note that in fact later surveys by H.J. Fischer and R. Mühleisen (*Meteorol. Rundsch.*, **25**, 6; 1972), and Z.P. Kleimenova (*Meteorol. Gid rol.*, No.8, 64; 1967) using more recent data fail to find significant positive correlations between thunderstorm frequency in Siberia and sunspot numbers. Indeed Kleimenova reveals that she could not find records from as many stations as Septer claimed to have used. Kleimenova then attempted to verify Septer's result with all the available data for the same period and concluded that "the results obtained by Septer are not in accord with fact. . .". How unfortunate that one of the most spectacular and oft repeated claims in the literature rests on data which can no longer be found! What weight can we give to this claim?

The second example is the authors' treatment of the claims by Xanthakis for large and significant positive or negative correlations between zonal indices of precipitation and sunspot activity. Herman and Goldberg here faithfully report the reversals of sign in correlation coefficients between zones and between epochs in the same zones and also note the inconsistencies of J. Xanthakis' results (in *Solar*

Activity and Related Interplanetary and Terrestrial Phenomena; Springer: New York; 1973) with those of E.S. Gerety *et al.* (*J. atmos. Sci.,* **34**, 673; 1977) and M. Dehsara and K. Cheak (*Arch. Met. Geoph. Biokl.,* Ser. B, **18**, 253; 1970). But they seek to explain these, not by a critical examination of the conclusions of, methodology, and data sets used by Xanthakis, but by appealing to a more complex hypothesis allowing more degrees of freedom. Thus on page 130 they say "If the pattern of the global distribution of excess rainfall . . . undergoes secular changes due to long-term variations in extraterrestrial or even terrestrial influences, averages over wide geographic expanses could very well exhibit correlation reversals with sunspot number . . . Analysis along (these) lines might reconcile some of the discrepancies . . .".

This is a common argument used by the protagonists of solar effects but in the absence of specific theories as to how things ought to change in time or space it simply allows infinite room to manoeuvre, 'explaining' all inconsistencies and proving nothing. It is to the authors' credit that they make this argument fairly explicit in a section headed "Correlation Reversals and Failures", but it is nevertheless a dangerous argument since it removes the incentive towards a truly critical examination of the claims in the literature. As if to prove my point, subsequent admissions by J. Xanthakis (*Nature,* **280**, 254; 1979) that he in fact selected his data *a posteriori* have now clearly invalidated the significance of his claimed results.

Similar criticisms can be made of the authors' rather uncritical acceptance of many other contradictory claims in the literature, for example in their discussions of much of King's work, including King's treatment of rainfall at Fortaleza (pages 119-120) and of Bowen's claims for Australian rainfall (pages 88 *et seq*).

So far my comments have been rather negative. However I want to pay tribute to Herman and Goldberg for several important things. One is the comprehensive (if not complete) nature of their survey and its clear presentation. In particular the excellent indexing greatly enhances the value of the book. Their highlighting of some of the important inconsistencies and breakdowns in the reported correlations is another big plus.

Perhaps the greatest virtue of the book is its emphasis on the need to develop and test physical theories without which the study of solar-weather/climate relationships will never emerge from its present morass. This emphasis will be found in the authors' very first sentence (Preface, page v) and is substantiated in a chapter devoted to possible "Physical Processes and Mechanisms" (chapter 6) and in the final chapter "Guidelines for Experiments" (chapter 8). Inevitably, coming from people deeply involved in research in relevant areas, this emphasis seems to be rather self-serving. Nevertheless it is a necessary and correct general emphasis, whatever we may think of their particular suggestions and their too ready acceptance of apparently relevant but dubious claims in the literature.

In summary then, I find Herman and Goldberg's book to be comprehensive (although not perfectly so) but regrettably uncritical in its approach to the literature. It has a desirable emphasis on the need for physical theories and explanations, and on attempting to isolate critical experiments. It also draws together information concerning a wide range of possibly relevant phenomena and processes. Although the case for rejecting the null hypothesis that there are no significant effects has not been proven by this book, there nevertheless remains a case for supporting further research directed with physical insight at the hypothesis that there just might be significant effects. We might at least usefully attempt to see how far down such effects penetrate into the atmosphere and to set upper limits on their magnitude in the troposphere. Read with healthy skepticism and critical discernment, Herman and Goldberg's book makes a useful contribution to such an effort. ☐

Kinetoplastid biology

J.R. Baker

Biology of the Kinetoplastida. Vol. 2. Edited by W.H.R. Lumsden and D.A. Evans. Pp.738. (Academic: London, New York and San Francisco, 1979.) £45; $94.

VOLUME 1 of this two-part work is an invaluable reference on trypanosomes and leishmanias, serving as an 'in-filler' of gaps in other standard works as well as presenting new developments in better-known fields. The present volume seems certain to follow suit. Its net is cast wider than its predecessor's, but the emphasis of its fifteen chapters is on parasites of man and domestic animals.

J.J. Shaw and R. Lainson review the ever-changing scene of leishmanial taxonomy and epidemiology and introduce three subgeneric "sections". R. Killick-Kendrick fully discusses *Leishmania* in its vector; and V.P. Sergiev describes the epidemiology of leishmaniasis, now mainly zoonotic, in USSR. M.A. Miles discusses biochemical and immunological heterogeneity of *Trypanosoma cruzi* and the problems arising therefrom; and its pathogenesis and biochemistry are reviewed respectively by W.L. Tafuri and by W.E. Gutteridge and G.W. Rogerson. W.E. Ormerod considers old and new concepts of the life cycle of *T. brucei* in mammals and heretically suggests that it is not the "stumpy" form which infects tsetse, and that a special "tissue phase" exists. W.J. Herbert and D. Parratt stimulatingly discuss virulence ("the capacity . . . to damage . . . its host") and heterophile antibodies in (almost exclusively African) trypanosomiasis, speculating on their significance.

Other chapters deal with kinetoplastids of arthropods (F.G. Wallace), lizards (V.C.L.C. Wilson and B.A. Southgate), fish (J. Lom), including lists of 149 alleged species of *Trypanosoma* and 33 of *Trypanoplasma*, and rodents (G.A.T. Targett and P. Viens), with emphasis on recent immunological work (much of it their own). Two general chapters include one on nutrition (S.H. Hutner, C.J. Bacchi and H. Baker) and one on characterisation, nomenclature and maintenance (W.H.R. Lumsden and D. Ketteridge).

Inevitably, perhaps, the choice of topics and their arrangement seems somewhat random; some deal with well known groups, presenting new information and syntheses, while others deal with parasites less often reviewed. Both groups are valuable, all contributions being authoritative, concise, comprehensive and comprehensible. Standards of editing and production are high — as, alas, is the price. There is a good general index (though the alphabetisation under the massive subheading *"Trypanosoma"* takes some getting used to), but no author index. Altogether, a volume to be recommended and either bought or coveted by all teachers or researchers of the kinetoplastids: it is sad that further volumes are not planned "at present". ☐

J.R. Baker is at the MRC Biochemical Parasitology Unit, Molteno Institute, Cambridge, UK.

- The second edition of *The Dynamics of the Upper Ocean*, by O.M. Phillips (for review, *see Nature,* **272**, 194; 1978), has been published by Cambridge University Press in paperback at £7.95.

- In the review of *Image Analysis, Enhancement and Interpretation,* by D.L. Missell (*Nature,* **282**, 885; 1979), the prices were incorrectly quoted, thus making the final criticisms of the reviewer unfounded. These should have read: Hardback $60, Dfl.135; paperback $31.75, Dfl.65.

- In the review of *Scientific Models and Man* (*Nature,* **283**, 113; 1979), the name of one of the lecturers was incorrectly quoted. This should have been: Donald Michie.

Planetary harmony

David W. Hughes

The Harmony of the World: A Realization for the Ear of Johannes Kepler's Astronomical Data from Harmonices Mundi, 1619. Gramophone record. By John Rodgers and Willie Ruff. (Sky Publishing: Cambridge, Massachusetts, 1979.) $11.50 (including postage and packing).

KEPLER, apart from being one of the greatest, is also one of the more endearing astronomers because of his habit of including in his books a detailed account of the blind alleys he went along as well as the paths of success. He was convinced that the ways in which knowledge is acquired are as important as the knowledge itself. It's a pity more people don't think the same today.

One of Kepler's main goals in life was the discovery of the mathematical rules underlying the progression of planetary orbital sizes, shapes and periodicities. A blind alley on the journey to this goal was the hypothesis of planetary harmony — the mathematical music of the spheres. To quote from Kepler's book *Harmonices Mundi:* "The heavenly motions are nothing but a continuous song for several voices, to be perceived by the intellect, not by the ear; a music which, through discordant tensions, through syncopations and cadenzas as it were, progresses toward certain predesigned six-voiced cadences, and thereby sets landmarks in the immeasurable flow of time".

Each planet produces a tone proportional to its angular velocity as seen from the Sun and a tonal range which depends on the orbital eccentricity. The frequency of the note is a function of the heliocentric distances. Figure 1 shows the notes that Kepler thought the planets played.

Now Kepler might have been content to perceive the heavenly chords 'by the intellect' but I have always wanted to hear them in reality and to listen to how they change as the planets orbit the Sun. Thanks to Professor Ruff of the School of Music, Yale, and Professor Rodgers of the Geology Department of the same university, this is now possible. The first 'fixed point' of their realisation is the mean frequency of the Earth, which they set at 800 Hz — very close to the g″ (a musical expression for the g note about an octave and a half above middle c) shown in Figure 1. The second fixed point is the orbital period of Pluto (248yr) which they musically set to be 20 min 42 s. Ruff and Rodgers have updated Kepler by introducing Uranus, Neptune and Pluto. As these planets have such low frequencies they have been simulated by a series of rhythmic beats — Uranus around 10 to the second, and so on. The long playing record covers the harmony of the spheres between 27 December 1571 (Kepler's birthday) and 1835. The record also includes introductions to the planetary sounds one by one. This sequence would have been much more useful if there had been a voice announcement introducing each planet.

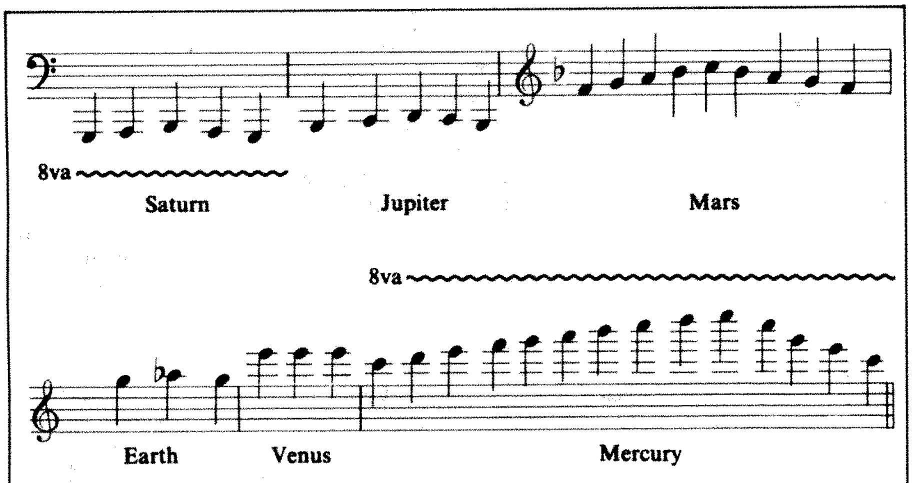

Figure 1 The 'notes' played by the planets.

Scientifically the record has considerable curiosity value, and the inclusion of copious sleeve notes and a copy of an explanatory paper by Rodgers and Ruff *(American Scientist,* **67**, 286-292; 1979) makes it all the more useful.

Musically the sounds have been computer generated using an IBM 360/91, and I am in deeper water. My scant musical knowledge comes from struggling through to Grade 8 piano and my musical appreciation falls into the "I know what I like" category. Bearing these facts in mind I conclude that this record put on near the end of a party would be guaranteed to clear the room in minutes flat. ☐

David W. Hughes is Lecturer in Physics and Astronomy at the University of Sheffield, UK.

Statistics in particle physics

H. Muirhead

Probability and Statistics in Particle Physics. By A.G. Frodesen, O. Skjeggestad and H. Tofte. Pp.501. (Universitetsforlaget: Bergen, Oslo and Tromso; Columbia University Press: New York, and Guildford, UK, 1979.) NKr.150; $30.

WHEN I saw the name of Skjeggestad among the authors of this book, I immediately recalled a set of lectures given by him on phase space at a CERN post-graduate school in 1964. These lectures were published as a CERN yellow report and have been part of the staple diet of research students ever since. I can see this book being used in much the same way, but not only by research students.

This book is no 'fly-by-night' progress report. It contains much solid, and at times, difficult material presented in a readable way. Although it is aimed at particle physicists the clarity of presentation should give it wider appeal. The many examples are excellent and treat real situations in particle physics. There was for me one notable omission, however, namely the treatment of the significance of a bump ('Breit-Wigner') on a background. If the bump is big and narrow and the background flat then there is no problem. If the bump is not so big and coincides with the peak in the background and one is not completely sure about the shape of the background, then the procedure becomes tricky to put it mildly.

One further thing I would like to have seen. A general warning (almost like on cigarette packages) about using common-sense, as the treatment of errors can drive one mad. I have too often seen computer output from students containing measured quantities with nonsensical errors or χ^2, not because the error treatment was wrong but because it had not been applied in a sensible way. One finds hints of this in the book — on page 289, for example, in discussing "pulls" the reader is advised to throw out a nonsense point from the data if he gets a bad value for χ. However, I would like to have seen a more general warning given, possibly in the preface. In reading the preface I noted that the authors paid tribute to Kendall and Stuart for their *The Advanced Theory of Statistics* (Charles Griffin: London, 1963) in three volumes, which they constantly consulted. It was also my staple stand-by 30 years ago; then it was in two volumes and had one author. I wish the present authors good fortune. ☐

H. Muirhead is Reader in Physics at the University of Liverpool, UK.

Facets of the fern

R.M. Lloyd

The Experimental Biology of Ferns. Edited by A.F. Dyer. Pp.657. (Academic: London, New York and San Francisco, 1979.) £37.50; $79.

FERNS exhibit all basic phenomena of the life-cycles of vascular plants in a form which is exceptionally suitable for experimental investigation. In spite of their geological age, the group as a whole is in an active state of evolution. Although numerically small relative to the rest of the world's flora, their contribution to our understanding of the physiology of differentiation and development, genetic systems and evolution, cannot be underestimated. This multi-authored book is an attempt to put together in one volume an overview of the ultrastructural, biochemical, physiological and genetical research which has taken place during the past 40 years in experimental pteridology. All significant facets of the fern life-cycle are covered, from meiosis and spore initiation, through gametophyte morphogenesis, gametangial initiation, gametogenesis and the influence of antheridiogens, to sporophyte development, apogamy, biosystematics and experimental ecology. The book is intended to make more biologists aware of the experimental research already completed in ferns as well as their potential for further highly productive research. To facilitate this, all of the authors have quite exceptionally circumscribed the available literature in their respective fields and have stressed not only those aspects which are in need of further work but also the currently prevalent controversial hypotheses.

Contributions of particular note are those by Peter Bell, who discusses the fern life-cycle in the conceptual framework of vascular life-cycles as a whole and presents the case for the cytological control of gametophyte sex as well as the evidence pertaining to the expression of gametophytic and sporophytic genes in spores and zygotes; Ed Klekowski, who summarises much of the evidence in support of his controversial theories on homoeologous chromosome pairing and the genetic system; J.M. Pettitt, who details our relatively meagre knowledge of spore wall structure, morphogenesis and cytochemistry; and Richard White, who effectively perpetuates the opposing arguments on the extent of developmental activity in the shoot and root apical systems. Over half of the text is devoted to research on the gametophyte generation, reflecting accurately the heavy emphasis it has received due, no doubt, to its ease of culture and manipulation. In contrast, modern ecological work in ferns is severely limited and the contribution by Chris Page adamantly exposes the critical need for further work in this area.

As this volume is technical and an excellent literature summary and as it emphasises the current sophistication and problems of experimental pteridology, it will be an important reference book for years, if not decades, to come. I, for one, am extremely pleased that it has appeared.

R.M. Lloyd is Associate Professor of Botany at Ohio University, Athens, Ohio, and is Vice-President of the American Fern Society.

Basic statistical mechanics

P. T. Landsberg

Convexity in the Theory of Lattice Gases. By R. Israel. Pp.167. (Princeton University Press: Princeton, New Jersey, and Guildford, UK, 1979.) £10.40.

BY developing a series of theorems of considerable abstractness and generality, the author links together the statistical thermodynamics of lattice gases (for example using models) and the theory of convex domains. The connection between the convexity and homogeneity of thermodynamic functions is considered (a) in a finite system and (b) in the thermodynamic limit when the number of particles n and the volume v of the system both tend to infinity in such a way as to keep their ratio constant.

This book is clearly essential reading for those interested in the modern discussion of basic statistical mechanics. It requires familiarity with the technical mathematics developed by Ruelle and colleagues. Both the concept of Hausdorff dimension and Banach space are here needed for a discussion of the Gibbs phase rule, which is treated in the sixth and last chapter of the book. New proofs concerning the existence of phase transitions are given in chapter five, by means of a modification of a theorem in pure mathematics about convex sets, which was given in 1963 by E. E. Bishop and R. R. Phelps.

To extract the physical significance of the results beyond the rather general indication given above is difficult, even if adequate space were available in this review. The job of obtaining an intuitive understanding of these detailed results is eased by the masterful Introduction which is provided by A. S. Wightman in 81 pages. Even so, much 'vulgarisation' will have to be done before this topic will find its way into the textbooks. □

P. T. Landsberg is Professor of Mathematics at the University of Southampton, UK.

Quantitative electron microscopy

V.E. Cosslett

Introduction to Analytical Electron Microscopy. J.J. Hren, J.I. Goldstein and D.C. Joy. Pp. 601. (Plenum: New York and London, 1979.)

THE history of light optical microscopy has shown a steady progression in the use of methods for obtaining quantitative information about a specimen. Modern high-power microscopes permit measurements of absorption, refractive index, birefringence and so on, as well as morphometry. It is not surprising, therefore, that electron microscopy is following the same trend, but with greater acceleration. During the past 25 years a whole range of *In situ* analytical techniques have been developed, from crystal structure determination by microdiffraction to localised chemical analysis by X-ray excitation and energy-loss spectrometry.

The present volume presents the first comprehensive attempt to bring this battery of research tools to the attention of electron microscopists. It comprises the lectures at a "Workshop" with the same title which was part of the annual meeting of the Electron Microscopy Society of America in August 1979. The editors succeeded in persuading the 22 co-authors to provide their manuscripts in time for the book to be printed and handed to participants when they arrived in San Antonio. Any editor of a collective work will appreciate the magnitude of this achievement, partly dependent perhaps on the use of a word processor.

We thus have available a complete review of the subject, starting with basic chapters on image formation and the electron optics of the microscope, through the instrumentation and application of the various analytical techniques, to discussion of radiation damage effects and the computer simulation of images. All the authors are expert in their particular fields, so that the numerous references are well selected and up-to-date. As acknowledged by the editors in the preface, such an enterprise undertaken at such a speed has inevitably resulted in a fair number of minor errors both technical and typographical. In view of the value of the product of their labours, however, we may accept the plea that these are "tolerable imperfections under the circumstances", and wish them the opportunity of a second edition in which they can be corrected. □

A dearth of new drugs

THE Californian court case in which Mrs Betty Mekdeci is trying to establish that *Bendectin*, an anti-nausea drug manufactured by Richardson Merrell, was responsible for the deformities with which her son was born, can hardly have come at a worse time for those who thought they could at last see some light at the end of the tunnel of regulations in which the pharmaceutical industry has found itself since the thalidomide tragedy of 1961. Whatever the outcome of the case against *Bendectin* the blaze of publicity surrounding it is bound to make this a less than opportune moment for the political turn-about on regulations that seemed to be imminent, at least in the UK. Therefore it is important that the *Bendectin* case is used to illuminate rather than to obscure the arguments for and against relaxing regulations.

The pharmaceutical industry is prone to claim that were the regulations of the American Food and Drugs Administration to apply worldwide, no new drug would ever reach the market. Although that is hyperbole, it is true that regulations are more restrictive in the US than even in the UK which has the stiffest regulations in the European Economic Community. It is also true that the figures underlying the claims are dramatic. Compared to 20 years ago, it now takes about three times as long from the discovery to the marketing of a new drug. The demands for drug testing before marketing have risen enormously, some would say 100-fold. The number of new drugs that reach the market each year has been halved. The cost of developing a successful drug now varies between £3-5 million. For every drug that reaches the public, several will have failed at the stage of clinical trials and many hundreds will have fallen by the wayside at an earlier stage.

Not too many tears need be shed in response to these facts. Drug testing by the industry used to be inadequate in both quantity and quality. In the immediate aftermath of thalidomide,better testing was either adopted by or forced upon the industry. But instances of inadequate testing continued to come to light thereafter and even if those instances were the whole, rather than the tip, of an iceberg, they provided some justification for the increasing stringency with which the whole industry became regulated. There has also been justification for the mandatory introduction of new and more sensitive methods of testing whatever the costs to industry.

Without a doubt the new drugs which now reach the public are safer than they used to be. The fact that there are fewer of them not only reflects the earlier detection and removal of hazardous drugs but also the growing and justifiable bias by regulators against "me-too" drugs, which ape the successful product of a rival, and in favour of truely innovative products.

On the other hand, regulations have had an irresistible tendency to breed further regulations because, faced with the possibility that lives are at stake, any regulatory body will understandably play safe. If a better, or even just a supplementary, test can be added to those already in force, it is safest to insist that it be carried out. Would it not be better to ask for the drug to be tested in an additional species? Why not replace a three month drug dosing period by one of a life time; and then why not insist on testing for any effects on the generation—or two?

By playing safe, the regulators are protecting themselves in the event of any unforseen tragedy as well as protecting the public. It is, however, possible to be over-protective towards the public. Regulations desgined to keep out the bad can also keep out, or at least hold up, the introduction of the good. That is what the pharmaceutical industry claims has happened to an unreasonable extent.

Much of their venom is directed against the bureaucrats. Why, they ask, does it take months for the UK Committee on Safety of Medicines to decide whether or not to grant permission for a clinical trial and up to a year for approval of a marketing licence after the clinical trial has been completed? (To which a partial answer is that it takes a long time to sift through the amount of evidence that is currently demanded and even longer when the evidence is inadequate or badly presented). More fundamentally, the industry and much of the medical profession, argue that, as a way of testing for hazards, animal testing and even clinical trials have limitations which are not adequately recognised. As a result too much time and effort, not to mention money, is devoted to trying to avoid what is unavoidable at that stage.

Animal tests will never provide a complete guide to human reactions to a drug and a clinical trial can never be on scale that is sufficient to detect side reactions of low incidence. It is argued that the path of a new drug both up to and through the clinical trial stage should be made easier. In return more attention should be paid than at present to the post-marketing stage. In other words the public should opt for taking more risks because of the greater benefits that such a decision would bring, on balance.

The general line of argument in favour of relaxing regulations is persuasive, but should only be met with a cautious practical response. There may be a case for cutting back on animal testing but if so, it is only on quantity in a limited number of respects and not at all on quality. There probably is a case for allowing and encouraging regulatory bodies to give a rapid, provisional go-ahead for companies to mount a clinical trial or even to market a new drug on the basis of a summary of the evidence before it is examined in full. But that procedure should be reserved for really innovative drugs and should not remove either the obligation for the company to provide the full evidence or for the regulators to examine it and, if necessary, to withdraw their provisional permission.

Finally, better ways will have to be devised for the monitoring of drugs once they are in full scale use. Although this is widely admitted in principle, there is little doubt that it will be resisted in practice, not least because it is likely to involve a cumbersome bureaucratic mechanism. However, had an adequate monitoring system already been in operation, we would surely have been spared, in one way or another, the need for the dramatic and emotional court room drama that is currently bringing anguish to the many women who took *Bendectin* early in their present pregnancy. □

United States

Universities push for creation of advanced energy research centres

US universities are pressing the Carter administration to help set up a number of university-based advanced energy research centres, concentrating on areas of interdisciplinary research that currently fall between the mission-oriented R&D programmes of the Department of Energy and its basic research commitments.

In his budget request to Congress for the fiscal year 1981, the President has suggested that $3 million be allocated to the department to support the initiation of such centres, an idea formally suggested only last October by Dr David Saxon, president of the University of California.

The universities hope that the administration can be persuaded to contribute more than $150 million over the next three years both to establishing 15 such centres, and to provide a national support programme of grants, traineeships and fellowships.

Administration officials are approaching the scheme cautiously, however, pointing out that the value of such centres should be judged on their scientific merits — and sceptical of any demands to institutionalise university research efforts.

The decision to provide the initial funding for a number of centres, albeit at a much lower level than the $15 million Dr Saxon had suggested, reflects a growing desire within the Department of Energy to emphasise the potential role of universities in carrying out what is referred to as "goal-oriented basic research".

In the 1981 budget request for the DoE Office of Energy Research, for example, funding for university-based energy research is scheduled to increase by 22%, a real growth of about 12%; in particular, "university research support", which includes the new interdisciplinary centres, would more than double, from $7.1 million to $14.3 million.

The specific proposals made by Dr Saxon were backed up by a report which he commissioned last August from the Association of American Universities. Prepared by a committee under Dr Jack Hollander, associate director of the University of California's Lawrence Berkeley Laboratory, the report was on Dr Saxon's desk within five weeks, and passed to Washington shortly after.

The main foci of the report are claimed gaps in the department's research strategy — and the way that universities might help to fill them. In particular, the report claims that the heavy emphasis within major R&D programmes on short-term technology development "inhibits the pursuit of goal-oriented basic research and the interaction of university researchers with the department".

In general it says that "much goal-oriented basic research tends to be considered too basic by the DoE mission-oriented programmes, and too applied by the DoE/OER basic science programmes". Examples of such research gaps, it suggests, can be found in fields such as synthetic fuels and nuclear waste disposal.

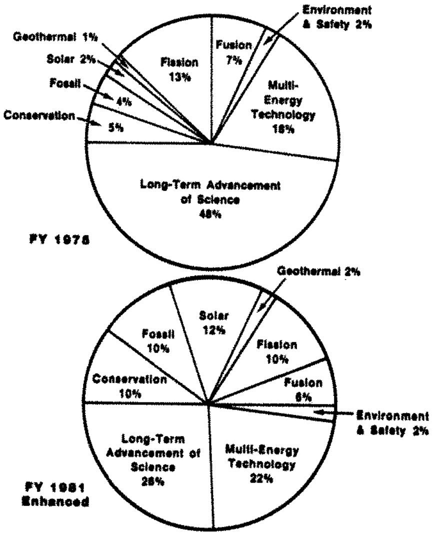
In transmitting the report to Dr Frank Press, director of the Office of Energy Research, and Dr John Deutch, undersecretary for energy, Dr Saxon spoke of the "urgent need for very substantial improvement and expansion" in the department's research strategy.

Building on the AAU report's conclusions, Dr Saxon suggested that the department agree to intiate support for five centres a year over the next three years, each centre receiving $2 million for "core support" and $1 million for scientific equipment.

Centres would be selected on the basis of a national competition. Each would build a "coordinated, coherent research programme around a central theme or subject"; styles would vary from new interdisciplinary laboratories in technical fields (such as the Materials Research Laboratories established by the Department of Defense) to interdisciplinary graduate study and research groups, such as the Energy Research Laboratory at the Massachusetts Institute of Technology.

Others might develop strong programmes applicable to a variety of energy technologies — such as research on high temperature chemistry applicable to nuclear, solar, fossil and geothermal technology — or involve research on the biomedical and social sciences related to energy supply and demand.

Shift in emphasis in Office of Energy Research support for basic energy sciences from 1975–81



The proposal was speedily processed by the DoE, and submitted in late December to the Office of Management and Budget as a last minute addition to the 1981 budget request. OMB agreed to provide $3 million for the scheme — expected to be enough to get four or five centres started — but insisted that further money would only be available if proposals are of a sufficiently high standard.

Dr Edward Frieman, director of the Office of Energy Research, told the Energy Research Advisory Board last week that proposals would have to demonstrate some special qualities, such as a strong interdisciplinary basis or close links with private industry, to qualify for funding.

"We do not want to see just a repackaging of our support for basic energy sciences", Dr Frieman said. "If the quality of the proposals is not high enough, I will not fund the programme".

Several major hurdles face the energy centres scheme, in addition to the scepticism of budget officials. One is the inevitable political infighting over where the first centres should be situated, given the traditional desire of Congressmen for 'equitable distribution' of federal dollars between geographical regions.

A second is the response of the national multipurpose laboratories supported by the DoE to a proposal that would seem to shift yet more research funding away from the laboratories into the university system. The department's budget proposal for 1981 is that the universities' share of OER funding should increase from 22% to 24%, with a corresponding reduction in the proportion of support from the national laboratories (although the latter have been provided with $60.3 million to improve basic facilities and their net funding will still increase).

Energy department officials, however, have currently taken as a key policy target the need to establish an adequate "technology base" for all its various energy-supply activities; and argue that, taking a leaf from the Defense Department's book and echoing the AAU, this can partly be achieved by emphasising goal-oriented basic enrolments research.

Universities, facing declining student enrolments and contracting research possibilities elsewhere, are keen to fit the bill. In the words of Dr Saxon: "A new programmatic departure . . . will signal the deliberate mobilisation of scientific talent in universities for the assault on energy problems of all sorts."

David Dickson

Fast breeder reactors delayed until after 2000

A declining enthusiasm for nuclear power in the US has led the Carter administration to stretch out still further research and development efforts leading to the deployment of fast breeder nuclear reactors. These are not now planned to come into commercial use until well beyond 2000.

In his budget request to Congress two weeks ago for the fiscal year 1981, President Carter reaffirmed his previous determination to halt construction of the liquid metal fast breeder demonstration project at Clinch River in Tennessee, a move so far resisted by Congress.

At the same time, however, the President has also recommended other broad cuts in the breeder development programme not proposed in previous years. This is in line with a decision taken late last year to stretch out the LMFBR programme and defer building breeder reactors, previously expected to come into use in the 1990s.

Administration officials are thought to believe that, given the current uncertainties surrounding the future of nuclear power, following the Three Mile Island accident, as well as adequate domestic supplies of uranium, it would probably be impossible at present for a new reactor type to be produced and licensed in the US. The Department of Energy had asked the White House to keep breeder funding at the 1980 level, apart from Clinch River.

Recommended cuts in the breeder programme include reducing support for LMFBR technology from $140 million to $80 million in 1981, and cutting out completely further development of the gas-cooled breeder reactor, currently being supported as a back-up programme.

Funding for research and development in fuel processing technologies for breeders is proposed to be reduced from $49.5 to $12 million, and plans for a conceptual design study for a larger scale plant than the Clinch River project will be terminated.

Overall funding for the breeder programme will, if Congress agrees, be cut from $761 million to $384 million. What actually happens, however, will depend on the outcome of the conflict over the Clinch River funding; until this is resolved, the administration is facing severe difficulties in producing a balanced programme for nuclear fission research.

Domestic cutbacks in the breeder programme have heightened the enthusiasm of energy officials for cooperation with other countries. In particular an exchange of agreement was signed with France at the beginning of December, through which it is hoped to work with French scientists and engineers. □

Canada

Election candidates asked for science funding commitments

Canadian scientists are mounting an active campaign to inform candidates in next week's general election of the need to increase support for university research. **David Dickson** reports

SOON after Canada's nine-month-old Conservative government resigned last month, scientists at the University of Toronto placed a letter on campus noticeboards asking for volunteers to investigate the attitudes of local candidates in next week's general election towards research funding.

Each volunteer is being equipped with a background kit on federal R&D policies prepared by groups such as the Canadian Association of University Teachers and the Canadian Federation of Biological Societies, and then assigned to candidates in one of Toronto's 23 ridings (constituencies).

The idea is to discover whether in general terms a candidate is prepared to support increased funding for research and development — or to provide information to those who have not considered the issue before — and also to report back on any commitments that a candidate may make.

These are checked back with the candidate's party, and noted for future use. "We are using this as a device to wheedle commitments, and if we get the commitments we are going to nail them," says Dr Ron Clarke, director of the University of Toronto's Office of Research Administration.

The scientists' campaign is being organised jointly by the CAUT, the CFBS, and other professional societies such as the Canadian Association of Physicists. With lobbying planned in more than 50 election districts, it is the latest tactic in an aggressive grass-roots strategy waged over the past few years to focus political attention on the relative lack of funding for university research.

Argument has been focused on the fact that government spending on basic research fell from 0.1% to 0.07% of the gross national product between 1969 and 1979, less than half that of most industrialised nations.

Responding to such criticisms, the Liberal government made a commitment to increase overall R&D spending to 1.5% GNP by 1983 shortly before losing power last year; and in November, Mr Howard Grafftey, Minister of State for Science and Technology, announced that the Conservative government proposed to increase the funding of the Natural Sciences and Engineering Research Council by 32%, to a total of $159.8 million, in the fiscal year 1980-81.

This increase was contained in the total budget figures over which the Conservative government was defeated in Parliament in December. But last week, with the election campaign in full swing, Mr Grafftey announced that NSERC's budget would be increased still further, to a total of $162.6 million.

At the same time, Mr Grafftey announced that the budget of the Social Sciences and Humanities Research Council would be increased by 16.2%, and that of the Medical Research Council by 17.4%bringing the total increase for the three research councils to 26.4%.

Budgetary levels for the councils approved by the Cabinet are for the first year of five-year plans which each has submitted. The increased funding has been welcomed by the scientific community, which feels that, whichever party wins next week's election, it will be difficult to go back to the lower increases previously projected. But there is concern over whether the increased level of funding will be maintained into future years.

The Party has publicly committed itself to an eventual target of spending 2.5% of the gross national product on R&D, although without being specific about timing. The small but growing New Democratic Party — which could hold the balance of power in a close ballot — has adopted the ambitious target of 4% by 1990 and 2.5% by 1983.

Many scientists doubt whether these are realistic targets, given the rapid sustained growth in funding that they would require. But there is determination to keep pressure on the new government to confer stability to the Canadian research effort.

One element of concern is that the new government should retain a minister with full-time responsibilities for science and technology. Another is that the provinces should play their part in the national effort to stimulate R&D; some have recently been criticised for diverting federal funds allocated — although not mandated — for the support of further and higher education.

In Toronto, the scientists claim their grass-roots lobbying towards such objectives is beginning to pay-off. Already one Liberal ex-Cabinet member has said his party, if elected, will appoint a full-time minister for science and technology. But what actually happens after election day remains to be seen. □

Poland

Science planning praised — but improvements still needed

SCIENCE planners and civil servants in the science-related ministries should improve their scientific qualifications, according to the "guidelines" for the Eighth Congress of the Polish United Workers' Party this week.

The "guidelines", which after due discussion will form the basis for the 1981-85 Five Year Plan, initially paint a glowing picture of successes scored by Poland's special approach to science planning, with its hierarchical structure of research tasks, from "Government" and "Key" down to "Departmental" problems. These achievements range from laser thermonuclear microsynthesis to mining tectonics, the mapping of Poland's flora and fauna, and the use of "Arctic Marine organisms" (ie krill) as a source of protein.

But it does seem that the "problem solving" structure of Polish research has not yet overcome the difficulty endemic throughout the Comecon bloc — that of implementing R & D results.

"It is absolutely necessary", say the guidelines "to introduce a system enabling universal incorporation of Polish inventions in national research and development endeavours. Contacts and cooperation among scientists, engineers and workers must be strengthened as an important vehicle of propagating technical progress and enriching the scope of innovations in industrial plants."

When it comes to the details of research planning, however, the "guidelines" show a certain ambivalence. On the one hand "the realisation of long-range research plans requires their closer connection to development programmes of the corresponding fields of the national economy". On the other, "more flexible methods of work must be developed in scientific as well as research and development units", and "the manner in which scientific research establishments are organised, their employment structure and planning methods, must be adjusted to changing needs."

To enable them to strike the proper balance between these demands, the staff of the relevant ministries are urged to continue their higher education "in cooperation with the institutes of the Polish Academy of Sciences and university-related schools".

The "guidelines" propose a number of "tasks" for the special attention of the science and technology planners. These come as no surprise, either within a world context (limitation of petroleum consumption, development of "unconventional" energy sources, and environmental protection) or within the special conditions of Poland (water management, development of high-protein and oleaginous plants, the development of specialised exports to the highly developed countries, and the export of Polish technical know-how).

But perhaps the most interesting "task" is "the production of pharmaceuticals . . . through the more extensive use of domestic syntheses and achievements in the field of genetics", a field in which, according to a recent article in *Polityka*, the commercial breakthrough point may be expected in the near future.

Vera Rich

United Kingdom

Study finds malnutrition in 7% of elderly

NUTRITIONAL problems among Britain's elderly population are highlighted in a report* published recently. "Nutrition and Health in Old Age", is the result of a survey of the nutritional status of 365 old people in 1972-73. The incidence of malnutrition was 26 (7%). It was twice as common in subjects over 80 years old.

Malnutrition was associated with both medical and social risk factors. Medical conditions included chronic bronchitis, dementia, depression, difficulty in swallowing, and poor dentition. The social risk factors included being housebound, living alone without regular cooked meals, bereavement, and being dependent on welfare benefits — though the report does say that "lack of money did not appear to be the sole cause of undernutrition.

Among the 26 were three with scurvy, two with osteomalacia, and 13 with nutritional anaemia associated with haematological evidence of iron, folate, or vitamin B_{12} deficiency. The remaining cases showed evidence of multiple nutrient deficiency. Diagnosis was drawn from clinical, dietary, biochemical and haematological studies; single clinical signs and isolated biochemical findings were considered to be unreliable.

The subjects were not a random population and the conclusions cannot be extrapolated to the population as a whole.

Alastair Hay

**Nutrition and Health in Old Age. Report on Health and Social Subjects, Volume 16. DHSS. Available from HMSO at £5.25.*

The Netherlands

Recombinant DNA research thrives

RECOMBINANT DNA research in The Netherlands is expanding at a rapid rate. At the end of 1976 only seven projects at universities had been registered by the commission of experts, established by the Royal Academy of Sciences in 1975 to look at genetic manipulation. By the end of 1979, there were 78 such projects, of which about 10 are with industrial companies, such as Unilever Research. All this research, according to the commission's latest annual report just published, will take place in category I and II laboratories.

The work of the Academy's commission has now been taken over by a government commission whose members include representatives of trade unions, the health authorities and industry. The Academy commission relaxed the safety guidelines in 1978. These came into effect a year ago and were extended to include yeast as a host organism. The new commission has already announced that it will consider a further relaxation of the regulations.

The chairman of the first commission — in a farewell speech — emphasised the need to build a category III facility which researchers say is needed in the country. The lack of such a laboratory has resulted in a falling behind in important research on, for example, cancer-inducing viruses and genetic aberrations, fields in which until recently The Netherlands had made progress. Even with a further relaxation of the regulations, Dutch scientists say that a category III laboratory is essential for research using DNA of warm-blooded animals and, in particular, man.

The previously strict rules in the country did not result in the departure of Dutch scientists to work abroad. Only seven researchers left temporarily to work in a category II or III facility, and five of them also asked foreign laboratories to work for them. But, in its last report, the commission says that it would be wrong to conclude that molecular biological research in The Netherlands had not suffered from the strict guidelines in force until recently.

In The Netherlands, especially in industrial circles, there is still a lot of dissatisfaction about the conditions in which molecular biologists must work. The public debate which reached a peak in June 1978 has now died down, and among scientists there is very little opposition to the relaxing of the guidelines. A long-awaited special committee to study the ethics and social aspects of work with genetic material has still not been set up by the Dutch government, but this is expected soon.

Casper Schuuring

Dioxin

Chemical company study shows no dioxin hazard

A REPORT to be published this month claims that workers exposed to significant quantities of the animal carcinogen 2,3,7,8-tetrachlorodibenzo-p-dioxin (dioxin) over thirty years ago have a normal incidence of cancer, and a reduced incidence of cardiovascular disease.

The report, published in the American *Journal of Occupational Medicine,* is an epidemiological survey of workers exposed to dioxin at the Monsanto Chemical Company's site at Nypro, West Virginia. 228 men are known to have been exposed to the chemical: 117 as a result of an accident in the 2,4,5-thrichlorophenol plant on 8 March 1949, and 111 in the routine manufacture of the herbicide 2,4,5-T. It documents the mortality indices for 121 of the 228 workers who were traced.

Acknowledging that these results are only part of the story, the report's authors — Judith Zack, an epidemiologist employed by Monsanto and Raymond Suskind, Director of the Institute of Environmental Health at the University of Cincinnati Medical Centre — say that details about the other workers will be published in due course.

Publication of this information by Monsanto is a welcome departure from the company's previous position of treating all information about these workers as confidential. Little was known about the Monsanto accident until July 1976 when a trichlorophenol reactor at the Italian town of Sèveso overheated, discharging dioxin over the town and its environs. In the aftermath of Sèveso, details began to emerge of at least 16 similar accidents in various parts of the world. Accounts of these accidents and their consequences were requested by Italian officials and scientists anxious to ascertain the consequences of the dioxin exposure for the people of Sèveso. Sadly, few companies have been forthcoming; this latest initiative on the part of Monsanto may have the effect of breaking the log jam.

A Monsanto spokesman described this latest report as "reassuring". But it is unlikely to allay all fears about the toxic properties of dioxin. For the results of the Monsanto survey differ from those following surveys of workers exposed to dioxin in West Germany and Holland. Workers known to have been exposed at Badische Anilin und Soda Fabriks' Ludwigshaven site in 1953 are reported to have suffered from a high incidence of gastrointestinal cancer, whilst others contaminated by the chemical at the Amsterdam site of Philips Duphar in 1963 are recorded as having a higher incidence of heart attacks (*Nature* 19 January 1978, p202).

Zack and Suskind note that their results do not agree with those obtained for German and Dutch workers. They also acknowledge that their survey does not confirm the higher than normal incidence of bronchiogenic carcinoma in workers exposed to dioxin in an accident in Czechoslovakia in 1964.

More recent evidence about the potential carcinogenic properties of dioxin are reported in a survey of Swedish forestry workers published in the *British Journal of Cancer* **39**, 711; 1979. According to its authors, Dr Lennart Hardell and Anita Sandström of the Center of Oncology at the University of Umea, exposure to dioxin contaminated 2,4,5-T or chlorinated phenols could be responsible for the six-fold higher incidence of soft tissue sarcomas seen in these men.

With so much conflicting evidence about the long-term effects of exposure to dioxin, the results of the Monsanto survey — albeit the largest so far — are unlikely to still fears about the risk posed by the chemical. The US Environmental Protection Agency has instituted a temporary ban on 2,4,5-T. Whether or not that ban should be made permanent will be decided after an Agency hearing on the herbicide due to begin on 11 March. The EPA will have to make sense of this conflicting data.

Alastair Hay

Mediterranean

No cash to clean up pollution

MEDITERRANEAN states have come up with only one third of the money needed to maintain the United Nations Environment Programme's Mediterranean pollution programme, UNEP's deputy director Peter Thacher announced in Barcelona on Monday.

Speaking at a meeting of the 17 signatories of the 1975 'Barcelona convention' on pollution in the Mediterranean, Mr Thacher warned "we have today only seven weeks left before we must stop" a number of the programme's activities. Jobs in the programme's 12-strong secretariat are also threatened: "a number of critical posts are filled on contracts which will expire in March unless new cash contributions are received", said Thacher.

A year ago, a meeting of the signatories in Geneva agreed to establish a trust fund of $6,480,000 to guarantee the programme for the two years 1979-80. The 17 states, plus the European Commission, were to contribute half, UNEP one quarter, and other UN agencies one quarter in goods and services. A year later, eight countries and the EEC had contributed nothing.

Only five countries have contributed in full, and these were among the smallest and poorest: Algeria, Tunisia, Cyprus, Malta, and Greece, providing $130,000 among them.

Among the major countries France has been the most forthcoming, with $990,000 of its agreed $1,564,000. Italy and Spain, however, which committed themselves at Geneva to spend $744,000 and $412,000, have so far contributed nothing, said Thacher. In total the countries have contributed $1,150,000 against an expected $3,200,000.

The next treaty to be signed is the treaty on land-based sources of pollution, the crown jewel of the Mediterranean programme. It was expected that states would sign the protocol in Athens this May and ratify it within two years, but, said Thacher, there were not even enough funds in the kitty to convene the conference.

Moreover land-based sources, particularly of untreated sewage, are the major cause of pollution in the Mediterranean, and would cost — according to rough estimates — some $15 billion to clean up. UNEP officials have been assuming that this money would be spent over some 10-20 years, representing a $1.5 billion to $750 million-a-year spend, 500-1000 times the present — and unachieved — target.

The 'Blue Plan', a proposed high-level economic and sociological study of the likely development of the Mediterranean region to the year 2000, is also threatened, though not by lack of cash. States had been asked last February to nominate two candidates each for six posts to implement the Blue Plan, but two months past the deadline only seven nominations have been received from seven countries. And, said Thacher, "very few of these candidates have sufficient academic qualifications or experience". He concluded that governments were "not serious" about the plan.

- In an extension of the UNEP Regional Seas Programme (of which the Mediterranean programme is a part) to the Caribbean, experts from 23 mainland and island states of the region have agreed to recommend to their governments an action plan on pollution and development. "In its economic and social aspects, the Caribbean Action Plan goes well beyond the Mediterranean Action Plan" says UNEP. The first governmental meeting on the plan will be held in September.

Robert Walgate

0028-0836/80/07613-01$01.00

NEWS IN BRIEF

US city bans nuclear waste shipments

THE city of Missoula, Montana (population 58,000) banned last week all shipments of nuclear materials through the city limits. Citing two accidents involving trucks carrying nuclear wastes that occurred this winter on Interstate 90 — which runs through the city's northern boundary — as evidence of the hazard involved, the City Council passed the ban by a vote of 7:1. The measure is expected to interfere with the shipment of wastes to the Hanford nuclear plant in eastern Washington. Included in recent shipments to Hanford are wastes from the accident at Three Mile Island in Pennsylvania.

Séveso director killed by political group

THREE men and a woman, ambushed Paolo Paoletti, aged 39, a director of the ICMESA chemical plant in Séveso outside his Monza home last week. The Italian urban guerrilla group, Front Line, claimed responsibility for the assassination. Paoletti was one of several senior ICMESA officials arrested and charged with operating a dangerous factory after four pounds of dioxin were released when a chemical reactor exploded in the factory in 1976. More than 600 children developed acute cases of chloracne as a result of exposure to dioxin. The legal case is still pending with the parent company Hoffman-La Roche of Switzerland expected to admit responsibility for damages caused, but not negligence.

UK radiation study overestimates safety

A BIENNIAL radiation survey conducted by the UK Health and Safety Executive has seriously underestimated the exposure to the workforce at 11 UK nuclear power stations by its exclusion of part-time workers from the study. Although claiming that none of the 7500 nuclear plant workers in either 1977 or 1978 received more than the international limit of 5 rems, the report did not cover an estimated 1500 temporary employees, many of whom were hired to do the hazardous work of pipe delagging in areas heavily exposed to radiation. It is not uncommon in pipe delagging operations for workers to receive their allowed quarterly dose of 2.5 rem in less than two weeks. These workers are then replaced by other temporary employees. An HSE official confirmed that the study did not cover "employees not directly employed by the Central Electricity Generating Board" and said that no figures were available on the numbers hired to do delagging or on the radiation doses they had received.

Health and Safety: Nuclear Establishments 1977 — 1978 HMSO £1.25.

More UK nuclear cracks

BOTH gas cooled reactors at Britain's Bradwell nuclear plant in Essex have been shut down to investigate cracks in the welds of the expansion bellows of the primary cooling circuit similar to the ones found in the Dungeness reactors two weeks ago (*Nature*, 17 January, page 238). The first Bradwell reactor had been shut down for routine maintenance when the cracks were discovered. As a safety measure the second reactor was shut down and similar cracks were discovered there as well. The reactors could be off line for a year or more.

UK centre for analysis of technical change

A NEW research centre for analysing technical change with the goal of "increasing national wealth" is to be set up by the Leverhulme Trust in conjunction with the Science Research Council and the Social Science Research Council. Leverhulme will contribute £1.5m towards the centre and the two research councils will each contribute £½ million over a period of the first five years followed by £250,000 a year for the second five years. Sir Michael Swann, FRS, will chair the organising committee and the centre's governing board. The types of issues to be considered include energy and material resources, manufacturing technology and unemployment. The majority of the proposed staff of 20 professionals and 10 supporting staff will be on secondment or will have joint appointments with universities, companies or government establishments.

Vietnam veteran records Agent Orange testimony

CHARLES HARTZ, a US Vietnam war veteran, who was exposed to the dioxin containing defoliant Agent Orange, initiated a massive law suit against the manufacturers of the chemical in Philadelphia last week. Hartz, who suffers from terminal brain cancer, videotaped his testimony accusing the manufacturers of negligence in not testing the chemical for its effect on humans. The pre-trial session had been organised by Hartz' attorney out of fears that Hartz will not live to testify when the trial begins later this year. In spite of objections from the manufacturers, District Judge George Pratt ruled that video tape was the best way of preserving Hartz' testimony. The law suit against Dow, Monsanto, Hercules, Diamond Shamrock and Thompson Heyward is presently being organised by 3000 exposed veterans but is still open to others.

20,000 demonstrate against Brittany reactor

TWENTY thousand demonstrators carrying French and Breton flags braved wind and rain squalls to march from the town hall in Plogoff to the site of a proposed nuclear reactor on Cap Sizan on the wild Brittany coast. Called to form part of a continuous protest to six weeks of hearings lasting until 14 March, the demonstrators plastered the town with slogans including a reminder to the government of its promise of April 1974 that "nuclear power will not be imposed on a population that refuses it".

Sussex physicist appeals to Queen over job

DR ROBERT Golub, a 42-year-old American physicist working at the University of Sussex, has appealed to Her Majesty the Queen over the termination of his research fellowhip. The Queen is 'visitor' to the university, a role following from its charitable status; in principle she acts as an ombudsman, caring for "breaches of the rules of natural justice" (in the words of one legal expert) but not for matters of academic merit.

Golub's research fellowship, which is payed for by the Science Research Council, has been renewed regularly since 1968 for his work on ultra-cold neutrons. A new neutron source he devised, using superfluid helium, is to be installed at the Institut Laue Langevin, Grenoble, for 700,000FF (£80,000), but without his assistance. Golub believes that an industrial tribunal would dismiss his case because of a clause in his contract which waives his redundancy rights.

The Privy Council has written to Golub telling him that it could intervene only if the university was guilty of "incorrect procedures or improper motives".

"I don't think you've much chance! Look who's in front of us in the queue!"

0028-0836/80/07614-01$01.00

Low expectations for Swedish PhDs

In Sweden, as in most European countries, young scientists are facing problems finding work. **Wendy Barnaby** reports on the falling market in research positions for newly-qualified PhDs

THE expansion in university teaching in the 1960s has not been followed by the creation of research posts for today's postgraduates, and many young PhDs in the natural sciences are finding it very hard to do research.

The expectations of young Swedish scientists have certainly fallen, yet they are hardly ever — strictly speaking — unemployed. According to Dr Bengterik Ronne, at the central administration of universities and tertiary education institutions (UHÄ), PhDs can still get jobs but they have to start at a lower level than they would have done a few years ago. This is borne out by figures published by the National Central Bureau of Statistics, showing unemployment amongst all licentiates (a qualification, now abolished, a little lower than a PhD) and PhDs, three years after graduation.

The latest available statistics cover the period 1976–1978, and continue a reasonably unchanging pattern in which most PhDs (as high as 90% to 98%, for this period) say they are employed wholly or partly within the field for which they were educated, with relatively qualified tasks. Only eight people over the whole period, out of a total of 1,008, said they were unemployed, and there is no way of knowing from the statistics whether they were licentiates or PhDs, or whether they had read social or natural sciences. But the statistics hide a lot of discontent.

Not many PhDs go into industry. "In the 1960s, Swedish industries were very optimistic about the numbers of PhDs they would need", says Professor Ingvar Lindqvist, Secretary of the Natural Sciences Research Council (NFR); "but when economic conditions changed for the worse, they realised they had overestimated their needs, and both industry and government lost interest in PhDs." According to Bengt Gustafsson at the central organisation of the academics' trade union (SACO/SR), there are only 700 PhDs working in Swedish industry, and most of them are chemists doing research in pharmaceutical companies.

Most natural sciences PhDs, then, end up in universities. But conditions there for them are far from good. The 185 who received their doctorates in 1976/77 had less than a one in ten chance of getting a research position (*forskarassistent*), which can be held for two three-year periods. A small number of PhDs are given grants by the NFR and hope to be supported by NFR funds for their entire careers.

Other options are to apply for grants from other foundations or become attached to research projects that are already funded. But all grants are very insecure, as Professor Lindqvist complains. "There is a general political philosophy in this country of security in jobs", he points out, "but it hasn't worked well at the universities. People get grants for one year at a time."

Under the security of employment laws in Sweden, a university is obliged to offer a research scientist another job at the same salary — either in his own department or in another one — if his grant dries up. But trying to find niches for displaced people can be a difficult problem, as one of the SACO/SR representatives at the Royal Institute of Technology (KTH), Dr Bertil Wilner, has found. "It's easier to find alternative positions for technicians and administrative staff", he says, "but for specialised research scientists it's a very hard problem to solve." He estimates that about 5% of KTH's research scientists find themselves in this situation every year. The security of employment laws provide legal assurance of an uninterrupted income but not of uninterrupted research in the same field: there is simply not enough research money to assure that.

Money is a problem at all levels of research. At the end of 1978, the NFR asked an international group of physicists to evaluate Swedish experimental nuclear and particle physics. "The first and overwhelming impression", reported the group, "was one of underfunding . . . More precisely, the present materials budgets for research per physicist are too low to guarantee efficient work. They are much lower than current standards internationally, most likely by a factor of two or three."

The group also commented on what it considered the "old fashioned organisation of research at the universities. Younger researchers with international reputations seemed unable to command permanent research positions. The near absence of intermediate tenure positions is disruptive and unhealthy for all long and medium term programmes. The present situation leads to an obsession with the necessity for personal research programmes with too many subcritical groups."

All this insecurity is having a distinct effect on PhD students, many of whom are increasingly reluctant to finish their doctorates. The PhD student is marginally more secure than the PhD graduate, even if, as UHÄ maintains, some students are forced to earn a living by taking on research not particularly suitable for their doctorates — another contributing factor to the decline in PhD examinations.

Since 1971, the numbers of natural sciences students passing their PhDs has dropped every year; and in 1976/77 it was less than in the mid-1960s even though recruitment to research education has remained fairly constant.

So far, the effects of these problems on research as a whole are not easy to point to. The international evaluation of physics made by the NFR, for example, did not mention any area in which Swedish research in physics is falling behind that in other countries, even though the evaluators often expressed their surprise about personnel and organisational set-ups; and Professor Lindqvist cannot point to any areas in which Swedish scientists are lagging.

But there are problems in sectoral research — research supported by organisations within their own fields of responsibility. According to Professor Erik Arrhenius at the Department of Cellular Toxicology, University of Stockholm, it is very difficult to get PhD students involved in research on the environment. The projects supported by the National Environment Protection Board (NEPB) run for one year at a time, and good scientists want more security than a one-year project can give.

The National Board for Technical Development (STU) has had similar problems with one-year projects. According to Dr Lennart Lindeborg, these problems have triggered the setting up of a new arrangement under which STU will guarantee the researchers' involvement in future projects for five years. The new projects will be in electronics, informatics, speech communication, food production processes, gene technology, the chemistry of wood, enzyme technology, the physics and chemistry of surfaces, fibrous materials and future industrial production systems.

Apart from the plight of present researchers, many are worried about the future. There is a fear that recruitment of graduates for PhD studies will decline. SACO/SR points to the slide in students

0028-0836/80/07615-02$01.00

completing three years of natural science subjects at universities from 1,390 in 1970/71 to 564 in 1976/77. Bengt Gustafsson maintains that this drop has resulted from the decline in university intake in 1972/73. As the numbers of new students fell off, so did the money for teaching staff; so the universities tried to make themselves more interesting by setting up short courses such as popular astronomy and amateur geology.

These courses have proved almost too successful: students now take them in preference to long courses that can lead to research. Professor Lindqvist thinks there will be a shortfall of PhD recruits in 15 to 20 years. He points to the increasing unpopularity of the natural sciences in secondary schools, saying that it is much easier to earn maximum marks (and it is marks which count for university entrance) in non-science subjects.

There have been piles of papers written about the reorganisation of the universities. Two more commissions will be reporting soon — one on the reorganisation of teaching structures and the other on the education of research students. The first commission is expected to recommend widespread changes to create more tenured research positions and spread the teaching burden more evenly amongst university jobs.

But the crux of the matter is money. Last year, Parliament allocated the UHÄ Sk205 million (about $46 million) to provide five universities with basic facilities with which to conduct natural sciences research: research education, fundamental research, professorships and appointments for those who had passed their PhDs, secretaries, libraries, instruments and buildings. Engineering research received Sk222 million (about $50 million), to be spread over six technical universities, for the same sorts of things.

As salaries, equipment and research funds all come out of the same budget, research gets less money as the universities have to go on paying the salaries of scientists whose projects have ended. According to Professor Lindqvist, the University of Lund has to pay more than SK2 million (about $450,000) a year supporting former docents.

All the relevant authorities are demanding more money, and all the political parties said before last September's election that more money should be given. The Swedish Parliament has in fact agreed that about 1,000 jobs in the public sector — in archives, museums, libraries, positions in planning, commissions of enquiry and some teaching posts at secondary schools — should be given in the first instance to PhDs.

The union also wants the state to give increased support to the development of technology-intensive industries such as telecommunications, energy and defence, to provide secure working places for scientists as well as competitive exports. □

How the popularisation of science narrows the polarisation of the people

In the last of three articles on science and technology in China, **Tong B Tang**, research fellow at Darwin College, Cambridge, UK, reports on scientific education and popularisation

Workers from three provinces of North East China watching a lathe demonstration at a gathering in Shenyang

EDUCATION has always been a central issue in Red China. By comparison, Marxist socialism in the West was also initially strongly associated with an educational movement; it stimulated developments in the philosophy of education, and was instrumental in spreading the concept of education for the working classes. This last influence was never necessary in China: in the past, non-hereditary mandarins were selected by imperial examinations which theoretically anyone could take. Traditionally the populace has been conditioned to appreciate the advantages of education. This deep-rooted exaltation of learning however, makes it all the more important to watch out for intellectual (as well as bureaucratic) elitism.

Two years ago China introduced a nation-wide examination for university entrance to replace nomination at one's place of work. Had everyone equal access to primary education, there would be equal opportunities for all. In practice however, students who can or want to take advantage of further education still tend to come from professional families. Another uneven situation is the formal existence of "key schools", (and universities) which admit "bright" pupils (from the age of five or six onwards) and whose facilities are given priority.

Going straight from high school to university is no longer rare but the long-standing policy of mobilising school leavers to work or settle in the countryside still persists, as affirmed by Chairman Hua in August last year. There are still many technical problems but this policy, besides playing other roles, spreads learning to the rural masses.

Another effective way in which the Chinese try to redress any imbalances in educational equality is their system of marking the university entrance exam. The pass mark is regionally adjusted, and lowered for candidates who have left school and are working in the countryside; ethnic minorities are also given 10 additional marks and educational work in secluded and border areas is paid special attention. Depending on the university (higher for a "key" one), the students need 300-400 out of a possible total of 500 marks to get in. Once there, freshers who come from poorer backgrounds are given extra

0028-0836/80/07616-03$01.00

tuition.

At present formal degrees are not awarded at the end of the period of study. This will probably change soon: undergraduates sent abroad are reading for degrees. The younger of those scientists sent to participate in research are also encouraged to register for postgraduate degress; the first Chinese to receive a PhD did so last September, in West Germany. The course structure, originally modelled on the Russian system which emphasises early specialisation, is being modified. Nanjing University, for example, introduced a credit system in 1978 similar to that used in US universities, where the student is freer to choose his or her courses. Summer schools at the pre- or post-doctoral level are also being planned.

At the same time, the Chinese are putting a lot of effort into updating teaching materials: there was a conference on this topic early last year. In most subjects, there are revised editions of former textbooks in circulation, and many universities are now trying them out. (In China most schools use a unified set of texts, while for universities about 70% of the curriculum is standardised by the National Planning Committee in the Ministry of Education.) A selection of course books recommended at major overseas universities is also being looked at. Some of these books may be purchased in bulk when the students are adequately prepared in the relevant foreign languages.

During the past decade most schools and university departments became linked to communes or factories, where pupils and students went periodically to work as part of their education. This scheme has ceased, since their main duty is now assessed to be academic study; so has the "inviting in" of workers and peasants who brought in grass-roots experience and argued with the students and their teachers. However, high-technology pilot plants or small manufacturing units, which provide contacts with workers can still be found in science faculties. More crucially, the long-developed tradition of political work has not disappeared. An academic works for six days a week, one of which is devoted to political study which may include physical labour on the campus. For students in any faculty, there is a 'core curriculum' of philosophy, political economy, Party history and the history of the international communist movement. It accounts for about 200 hours out of a total 2,500 curriculum hours and carries 8 to 10% of overall marks.

With a population of 1,000 million, China has 10 million teachers for 210 million students. Of these, respectively, only 0.2 and 0.9 millions are in the 598 post-secondary institutions. As a medium-term measure to achieve a rapid expansion of tertiary education, an increase has been made in the number of students sent abroad. There are at present 180 postgraduates and 420 undergraduates in North America, Japan and Europe, 80% of whom are in natural sciences. By comparison, 1,300 from the West and the Third World are studying in China. An unusual measure, further, is that a few self-paying students who can afford it are allowed to go abroad; some think that this may be seen to serve the principle of "to each according to his capital".

Scientists and peasants preparing a simplified medium for pollen breeding at the Institute of Genetics of the Academia Sinica

The opposite tendency, namely, "to each according to his needs", is fostered by a mass movement to raise the scientific and cultural level of the entire nation.

The objectives of science popularisation are not confined to education. It serves to drive out the out-dated ideas in the social consciousness of the whole people, and to generate greater enthusiasm for the Four Modernisations (in agriculture, industry, national defence, and science and technology). The idea is that science popularisation will reduce social polarisation by narrowing the differences between city and countryside, and by reducing the alienation due to the division of labour.

The organisation of popularisation is largely, though not exclusively, in the hands of provincial chapters of the Scientific and Technical Association which are directly responsible to local authorities.

The activities take many forms. In children's and youth clubs, science classes are held and model or instrument building competitions are regularly sponsored. Summer and winter camps teach subjects that range from geology to ecology. Educational exhibitions are shown in the camps too, and in public parks. Public lectures are frequent, sometimes by such leading scientists as Qian Sanquiang whom some foreigners dub the "father of atomic bombs in China".

There are popular science magazines and newspapers on sale throughout the country. No fewer than 1800 popular science books have been published since the beginning of 1978. In August 1979, an Association of Science Popularisation Writers was formed.

Science fiction based on hard science only is expected to flourish soon. Posters of great scientists are constantly in print. I saw the following: Newton, Einstein, Copernicus, Marie Curie, Darwin and the inventor Edison. But disappointingly I didn't find one of an ancient Chinese scientist. Visual arts with scientific themes are also being encouraged. More than 100 new educational films were scheduled last year.

Since May last year "universities of the air" have been started in 29 local TV and radio stations. Correspondence courses are also being extended. In a few years' time there may be twice as many students in these alternative forms of education than in the regular universities and colleges. Full-time schools are also being run to give technical instruction to administrative cadres. Party secretaries and bureau chiefs from the provincial level down and leading personnel in factories, mines and oilfields attend courses lasting two weeks to four months, in farm economics and machinery, stock-breeding, fishery, forestry, enterprise management or computers. It would be amusing for the mandarins in the British Treasury to have to go to evening classes in arithmetic.

It would be unhelpful and unrealistic to imagine that despite their enthusiasm, the Chinese have no major problems ahead. As reiterated in a recent editorial in the People's Daily, the question of manpower is the foremost obstacle to the modernisation programme, and to education in particular. Many scientists have little experience of research management: here the Chinese can learn a lot from the West provided they are selective. In the transformation of education is the teachers who constitute the single most crucial sector.

If the development of Chinese science is dependent on politics, then over the next two decades, China might well fulfil its aim of developing a science of its own. It has to be careful to avoid a Scylla of Westernisation and the Charylbdis of misguided dogmatism. The Chinese believe that the human activities grouped under the name of science are intimately related to other processes in society — "if society has a technical need, that helps science forward more than ten universities"; at the same time, dialectically the reverse is also true. Science acts on the technico-economic base and is therefore partially self-supporting. □

Friends and foes of science debate in France

Jim Ritter records some observations on what was "effectively the first public debate on science and technology in France for more than a decade". It was staged last month, by *Les Amis de la Terre.*

THERE is a sense of movement about French scientific policy today, a certain loosening of the tight strictures of official silence and lay apathy. What public debate there has been about science has taken place within the cloistered university circles of philosophers and sociologists, while science policy decisions continue to be taken in equal isolation by scientific and political mandarins.

Hence the strangeness to the Anglo-Saxon eye of the programme for a debate on science and technology policy organised by *Les Amis de la Terre* and held in Paris one weekend last month. There was little discussion of concrete points of technology — nuclear power safety, pollution, and so on. There was much of more epistemological questions — the nature of quantum mechanics, the question of systems analysis. But the main stress was biological; a reaction to the "biological determinism" now being vigorously propagated in France by a group of influential far-Right intellectuals (the New Right) who claim that modern biology has "proven" the inequality of races, sexes, and classes. The organisers did well in assembling, for virtually the first time in a decade, a number of top administrators, active researchers, authors and journalists to face a concerned public.

The debate started with a panel discussion among three physicist-philosophers on the interpretation of quantum mechanics. The hall was surprisingly full and the question of whether the Copenhagen interpretation was idealist or not was entered into with great gusto. But the debate was inconclusive, the question remaining rather elusive though the level of debate was one which, in the UK, would only be found in specialised seminars.

The afternoon session on bioengineering was livelier and more familiar. The panel consisted of three directors of biological research and two young researchers. The difference of opinion ran along the same line, the mandarins seeing no reason why genetic manipulation should not be prosecuted with all possible speed while the two opponents pointed out what they saw as disquieting experimental evidence and questioned the point of research. The audience of more than 100 readily joined in. They were clearly worried while the administrators were equally clearly unused to hostile questions and overracted. The scientists quoted particular experiments to support their claim that genetic manipulation was/was not dangerous but never seemed to come to grips either with each other's claims or with the general unease among the lay members of the audience.

Sociobiology, in the next session, generated a more unanimous attitude, with two of the three biologists on the panel having written recent popular books on the subject. A clear presentation of the basics of the theory, together with an uncovering of the political attitudes underlying its "objective, scientific" attack on women, non-whites, and the poor, led to one of the liveliest debates of the weekend. The discussion was continued into Saturday evening with further analysis of the particular use of women as a target by the New Right.

Sunday morning and it was the turn of systems analysis. Here both the panel and the audience were divided on the merits of a general systems approach. Some saw it as the answer, some would replace it with catastrophe theory, some saw any such search for a totalising theory which explains all levels of the universe at once as obfuscation. The search for and critique of panaceas went on into the following physics debate. Are microprocessors the solution or the problem? Will larger and larger particle accelerators advance physics as much as more modest investments elsewhere?

The final session was on social responsibility and the hall was packed to overflowing, the debate heated. The presence of trade union representatives and members of various political and environmental groups made this discussion the most familiar to the Anglo-American ear. But when one participant pointed out that "we've heard this all before, ten years ago", one was reminded of just how damaging the long silence in French public debate has been.

In any case the science policy debate has reopened in France after a long hiatus. Any facile optimism about how easy it would be to simply confront the "expert" and "the public" has evaporated after 20 hours of long and arduous discussion. For when two "experts" disagree, how is one to choose? And how can one pose the right questions without already knowing some of the answer? But *Les Amis de la Terre* are pleased with it and plan others for the future. □

NEWS AND VIEWS

Antarctic ice surges and theories of glaciation

from D.Q. Bowen

THEORIES of ice ages are never far from the limelight, but with the demonstration that the Earth's climate over the past 500,000 years has followed changes in the amount of solar radiation received at certain latitudes, as predicted by the Milankovitch model (Hays *et al. Science* **194,** 1121; 1976), the mystery seemed to be solved. But those authors would be among the first to admit that the model is really no more than a black box; a celestial mechanical input is followed by the output of a climatic signal. Although past behaviour of the climate can be deduced from oxygen isotope analyses of deep-sea cores, which allow inferences to be drawn concerning the interaction of the Earth's atmosphere, oceans and cryosphere, exactly how an ice age starts remains unknown. Any model should also explain not only how glaciation is initiated but also how it is brought to an end.

In 1964, A.T. Wilson (*Nature* **201,** 147) suggested that because the Antarctic ice-sheet is inherently unstable it would surge periodically into the southern ocean and form a huge ice-shelf. This would increase the Earth's albedo and the transfer of the consequent cooling to the northern hemisphere would lead to glaciation. Because the ice-shelf could not be sustained its eventual break-up would decrease albedo, heat would be transferred to the northern hemisphere and glaciation terminated. This was subsequently modelled and deemed eminently feasible climatologically (Flohn *Quaternary Res.* **12,** 135; 1979).

J.T. Hollin (*Nature* **208,** 12; 1965) pointed out that the global rise in sea-level after such a surge, possibly amounting to 15 m, should be capable of geological verification: that is, by evidence of a rapid, though short-lived, rise in sea-level at the end of interglacials. In 1977 (*Boreas* **6,** 33), he argued that it occurred at the end of oxygen isotope stage 5e, to initiate the Last Glaciation; but on page 649 of this issue of *Nature* he now suggests it was later, at the end of stage 5c. How is this shown? Unequivocal geological proof for such sea-level rises, and inferred surges of Antarctic ice, is difficult to obtain. How can a raised marine deposit be ascribed to such an event? In south-east England Hollin was able to show that some marine transgressions took place late in interglacials from the fact that their beach deposits overlie terrestrial ones dated by pollen analysis. Generally however, the rapidity of the postulated surge in sea-level, its brevity, and the incompleteness of the stratigraphic record, have conspired against a full and convincing demonstration. Nor is the surge likely to be recorded in the deep-sea cores, with their comparatively slow sedimentation rates, for it would have gone in less than 2,000 years — possibly considerably less.

Important new evidence bearing on the Wilson hypothesis comes from the Huon Peninsula, New Guinea, where a flight of uplifted coral terraces occurs more or less on the boundary between the West Pacific and Australian lithospheric plates. The old orthodoxy, which directed sea-level studies to stable coastlines (where, unfortunately, repetitive high sea-levels would have destroyed most pre-existing evidence), should now be received with caution, for the evidence is more effectively preserved in tectonically-rising areas. Provided that the tectonic factor can be separated from the depression caused in land level by the glacial masses of ice, which has been accomplished with considerable success in New Guinea (Chappell *Bull. Geol. Soc. Am.* **85,** 553; 1974) detailed records of sea levels are available at least for the past 130,000 years. Furthermore, the palaeoecology of the corals allows precise inferences to be drawn about rises and falls in sea-level. Unaltered aragonite coral may also be dated by $^{230}\mathrm{Th}/^{234}\mathrm{U}$ determinations. Thus much of the required critical data to test for sea-level surges is available.

P. Aharon, J. Chappell and W. Compston (page 669, this issue of *Nature*) show that the record is sufficiently good to establish, and date, sea-level fluctuations between 140,000 and 105,000 years ago. Stable isotope work on shells of the giant clam *Tridacna gigas* also provides information on the oxygen isotopic composition of the global ocean during this period. Because the clam lives in isotopic equilibrium with the ocean, a feature of some significance is an anomaly 120,000 years ago — during the Last Interglacial. This anomaly is interpreted as showing that water temperatures 120,000 years ago were cooler than at 130,000 years. Moreover the cooling took place within 1,000 and 2,000 years during a rise in sea-level of 8 m. Aharon *et al.* attribute this event to an Antarctic surge which caused sea-level to rise and transmitted cold water northwards. Thus the required geological test for Wilson's theory appears fulfilled. But did this event, 120,000 years ago, or the similar one identified by Hollin at ~ 95,000 years ago, initiate the Last Glaciation?

Evidence submitted in both papers is convincing; both use the relatively objective stratigraphic framework provided by the deep-sea oxygen isotope record. This, however, is concerned with chronostratigraphic 'Stages' — time-intervals defined from actual lithostratigraphic units (Shackleton & Opdyke *Quaternary Res.* **3,** 39; 1973) — and not with wholly inferred climatostratigraphic concepts such as 'glacials' and 'interglacials', or 'stadials' and 'interstadials'. It is quite possible that Antarctic surges occurred on several occasions not always related to interglacials as presently, and loosely, defined. In the period under consideration, a further difficulty arises from lack of agreement on how the end of the Last Interglacial should be defined. The classical Last Interglacial (Eemian) ended 120,000 years ago, but Woillard (*Quaternary Res.* **9,** 1; 1978) showed

---

D.Q. Bowen is a Reader in the Department of Geography, University College of Wales, Aberystwyth.

0028-0836/80/07619-02$01.00

that two further interglacials occurred before the Last Glaciation commenced, 70,000 years ago. Definition rests on the classical north-west European pollen analytical demonstration of deciduous forest woodland. This somewhat parochial classification has been generally and uncritically accepted everywhere.

This vexed question is not new; volume 2 (No. 3) of *Quaternary Research* (1972), was devoted to the end of the 'Last Interglacial'. It is clearly desirable to agree on the definition of Global Standard Interglacials in relation to Stages objectively defined. In terms of the two contributions in this issue, neither of the coolings which their respective authors attribute to Antarctic surges led directly to the maximum build-up of ice during the 'Last Glaciation'. It is not impossible that such surges were the rule rather than the exception and that many abrupt temperature falls in the Pleistocene record are to be so explained. Perhaps major periods of continental glaciation only took place when a combination of Antarctice surge and favourable Milankovitch conditions arose. □

Osteology and prehistoric society

from Stephen Shennan

RECENT work on the chemical analysis of human bone from archaeological contexts confirms and extends the potential of human osteological studies for throwing light on man's social and economic development.

Archaeologists are increasingly concerned with explaining cultural change in terms of the social and economic processes at work within and between societies. One important advance has been in the use of evidence from excavated cemeteries to reconstruct past social organisation. Quantitative studies of the grave goods of dead individuals and the form and degree of elaboration of their burial monuments have been used to reconstruct the development of increasingly complex and differentiated societies as well as, in some cases, their devolution to more simple forms (for example Peebles *Mem. Soc. Amer. Archaeol.* **25**, 68; 1971; Rothschild, *Amer. Antiquity* **44**, 658; 1979).

Remarkably little attention has been given to the body itself however. Apart from its sex and age at death archaeologists have shown little interest in the information to be gained from the skeleton, and the obligatory physical anthropologist's report usually remains an unintegrated appendix. However, an increasing number of studies, particularly from North America, shows that the skeleton can yield information on aspects of diet and biological stress in past populations which are otherwise inaccessible and are vital to an understanding of cultural change.

In a recent paper Lambert, Szpunar and Buikstra (*Archaeometry* **21**, 115; 1979) describe the results of a chemical study of the skeletons of two burial populations from the eastern United States. The first belongs to the Middle Woodland period, about AD 400, when hunting and gathering provided a great variety of foods. The second belongs to the Late Woodland period, about AD 1200, when maize farming is well documented in the area. The bones were analysed by atomic absorption spectroscopy after sample preparation by a new method involving virtually complete dissolution of the bone ash. Particular attention was given to the problem of contamination of the bone by the surrounding soil and the conclusion was reached that although concentrations of iron, aluminium, manganese and potassium may largely reflect soil contamination, strontium, zinc, calcium, sodium and probably copper and magnesium give analyses that are representative of the bone.

The authors were able to investigate differences within as well as between each population. In the earlier one males and females had statistically identical bone compositions for every element examined, whereas in the later one there were significant differences, males having lower strontium and calcium and higher zinc concentrations, all diet-related elements. It seems that dietary differences between males and females developed which it is tempting to relate to the development of maize cultivation, and which may be associated with a greater differentiation of sex roles; the lower strontium concentration for males is at least consistent with a higher protein diet. Equally interesting, at the earlier site, where archaeological information indicated that the population could be divided into three groups of differing rank, it seemed that while the upper two groups did not differ significantly from one another in any elements, there were significant differences between the lowest group and a combination of the upper two in strontium, zinc, magnesium and sodium, again diet-related. Here the archaeological and analytical results together can show how the social distinctions marked in the burial rites correspond to dietary differences in life, although the nature of these differences is not yet clear.

In this example the need of the archaeologist for the physical anthropologist and chemist is clear enough but Buikstra (*op. cit.*) has also shown how the anthropologist can be misled if he fails to take archaeological considerations into account. The high frequency of pathologies in certain North American skeletal series from habitation sites of the Mid-Archaic period, has been ascribed to the rugged conditions of life. However, Buikstra was able to show that this phenomenon was a result of the nature of the sample: normal adults were buried in separate cemeteries but individuals not able to perform the range of 'normal' adult tasks were buried in the occupation area.

The potential of integrated work is further illustrated in the recent study by J. Lallo and J. Rose of another two prehistoric populations from eastern North America (*J. hum. Evol.* **8**, 323; 1979). They selected two populations from a single site in a period for which there is strong archaeological evidence of social and economic change, the first belonging to the Mississippian Acculturated Late Woodland period, AD 1050–1200, and the second to the Middle Mississippian, AD1200–1300. During this time society became increasingly less egalitarian, contacts became more widespread, and subsistence came to be more dependent on maize. Infectious lesions in bone were twice as common in the later period, as well as being more severe. Porotic hyperostosis, a condition of the bones of the skull reflecting increased bone marrow activity, was also more common. This condition has been observed elsewhere in prehistoric maize-eating groups (El Najjar *et al. Amer. J phys. Anthropol.* **44**, 477; 1976) and interpreted as reflecting iron deficiency. Various dental defects reflecting nutritional stress were also more common in the later period. Finally, examination of the distribution of age at death in the two populations showed a decrease in the life expectancy from 33 to 24.3 years. Lallo and Rose go on to offer a systematic explanation of these phenomena, indicating the way in which the social and economic changes independently documented lead to increasing disease and nutritional stress.

One hypothesis of this type has been put forward recently by R. Santley and E. Rose for the Basin of Mexico, one of the cradles of Mesoamerican civilisation (*World Archaeol.* **11**, 185; 1979). They argue that between 1500 BC and the Spanish conquest major periods of population growth correlated with periods of balanced nutrition, whereas phases of population stability corresponded to times of nutritional shortages and stress. They suggest that in hard times the elite urban populations would have used their power to ensure an adequate nutritional base for themselves at the expense of the rural population. Whether or not their idea proves correct, its testing will bring

osteological analysis of the type described above into the explanation of some of the major developments in New World prehistory.

All these studies show the importance of using the osteological evidence to make inferences about the human biological changes which have accompanied social and economic development, and which not only tell us more about those developments but may themselves have been responsible for them in certain circumstances, providing one of the 'kicks' which set positive feedback processes in motion. □

Human teratocarcinoma workshop

Clinicians and mammalian embryologists are launching a concerted attack on human teratocarcinoma. The embryologists are moving on to this new challenge after some years spent manipulating mouse teratocarcinoma stem cell lines, obtained originally from tumours of the murine gonads. The value of such cell lines lies in the ease with which they can be induced to differentiate in a manner thought to be analogous to certain events of natural development. Although mouse development could hardly be said to be understood yet, insights into human development are now hoped for.

But embryologists are faced with the usual problems of working with human material. It is difficult to obtain, requiring the cooperation of surgeons who will ensure that a reasonable specimen is put aside before the whole tumour is claimed by a pathologist and doused in formalin. The problems of pathology and nomenclature are also formidable, and participants at a European workshop on human teratocarcinoma at Imperial Cancer Research Fund Laboratories (ICRF) in London on 28 January were not always sure what they were talking about. Nor were they all particularly confident of the difference between teratocarcinoma, seminoma and yolk sac tumour, although all three originate in the same anatomical region.

In future they will cooperate in obtaining cell lines and in characterising those already established. The workshop will gather again in the autum. Meanwhile information about the cell lines, their biochemical and immunological characteristics, is to be collected by Brigid Hogan of ICRF's Mill Hill laboratories for subsequent distribution. Later there may be a human teratocarcinoma newsletter.

Sails set for the myosin active site

from Peter Chantler

WHEREAS kinetic secrets are being prized almost daily from the myosin and actomyosin ATPase mechanisms knowledge of their structural aspects remains in the dark ages. The quest for structural information on the active site of myosin has been bedevilled by false leads. One example is that of the two thiol groups (SH-1 and SH-2) on each myosin head which were originally considered essential to the myosin ATPase mechanism, possibly being intimately involved with nucleotide at the active site. More recent studies however, have thrown doubt on the idea that these thiol groups are directly involved in the active site and a new twist to the story has recently emerged from Yount's laboratory at Washington State University. By an innovative technique in which the fate of radiolabelled nucleotide substrates was followed during chemical modification of myosin with cobalt, they have clarified some aspects of the relation of the thiol groups to the true active site and at last opened up a way for its unambiguous definition (Wells *et al. Biochemistry* **18**, 4793; 4800; 1979; Wells & Yount *Proc. natn. Acad. Sci. U.S.A.* **76**, 4966; 1979).

Taking advantage of the exchange characteristics of Co (II) and Co (III) coordination complexes, myosin subfragment 1 (S-1) was exposed to a mixture of $\mathrm{CoCl_2}$, 1,10 phenanthroline and $[\mathrm{Co^{III}}\ (\mathrm{phen})_2\mathrm{CO_3}]^+$ with a resultant inactivation of the ATPase activity (Wells *et al. Biochemistry op. cit.)* caused by tight chelation of one cobalt ion per mole S-1 which occurred in parallel with the loss of two sulphydryl groups. The mechanism proceeds by way of a S-1.$\mathrm{Co^{II}}\ (\mathrm{phen})_x$ intermediate ($\mathrm{Co^{II}}$ freely exchangeable) which undergoes exchange with $[\mathrm{Co^{III}}\ (\mathrm{phen})_2\mathrm{CO_3}]^+$ to yield a S-1. $\mathrm{Co^{III}}\ (\mathrm{phen})_x$ compound ($\mathrm{Co^{III}}$ not exchangeable). Such *in situ* oxidation of the bound cobalt is extremely mild; indeed, the S-1.$\mathrm{Co^{III}}\ (\mathrm{phen})_x$ can be reduced by short incubation with reagents such as $\mathrm{Fe^{II}}$EDTA which fully restore enzymic activity. The simultaneous loss of $\mathrm{NH_4}^+$-EDTA, Ca^+ and Mg^+-ATPase activities on cobalt binding and the blocking of the binding by *p*-N,N′-phenylenediamine (which crosslinks SH-1 to SH-2) identified the two sulphydryls lost as SH-1 and SH-2 and showed that these two thiols could be cross-linked by the cobalt and therefore approach to within 3-5Å of each other (the distance depending on whether there was *cis* or *trans* chelation).

When the fate of ^{14}C-labelled nucleotides was followed during the course of Co modification, inactivation of the ATPase amazingly paralleled incorporation of nucleotide so that complete inactivation occurred on simultaneous binding of one gram-atom of cobalt and one mole of nucleotide per mole S-1. This not only directly demonstrates the separate identities of the active site and the SH-1 and SH-2 thiols but also shows, consistent with other evidence, the interdependence of the thiol and active sites. When cobalt chelates SH-1 and SH-2, nucleotide at the active site is prevented from leaving; when nucleotide binds to the active site, cobalt chelates SH-1 and SH-2 much more easily. In addition, a new phrase enters the textbooks: active site trapping — a technique, in serendipitous cases, as here, of great potential power. When the experiment was performed in the presence of MgATP the trapped nucleotide always manifested itself as MgADP. Although the relationship between cobalt modification and nucleotide hydrolysis is unclear it is apparent from the relative rates of the two reactions that the trapped ADP did not originate from a rebinding of previously hydrolysed substrate.

As active site trapping seems to be equally effective in the presence of adenosine 5′-(β,γ-imido)-triphosphate, a non-hydrolysable analogue of ATP, the technique may well offer some insight into mechanism. But its real future lies in conjunction with photoaffinity probes such as 8-azidoadenosine triphosphate which the authors have also trapped (Wells & Yount *op. cit.*). The power of the photoaffinity probe, in more conventional mode, has been seen recently in the binding and incorporation of arylazido-β-alanine-ATP into proteolytic subfragments of myosin followed by tryptic proteolysis (Szilagyi *et al. Biochem. biophys. Res. Commun.* **87**, 936; 1979). The reagent labelled an N-terminal 25K peptide of myosin; there was no incorporation into the fragment containing SH-1 and SH-2. As this latter fragment is separated from the 25K peptide by a 50K peptide (Szilagyi *et al. op. cit.*) it is apparent that the sequentially remote 'essential' thiol region must be juxtaposed near to the active site in the tertiary structure of the enzyme.

Detailed speculations on which amino acids are involved at the active site of myosin are unwarranted but the most likely residue seems to be arginine (Mornet *et al. Eur. J. Biochem.* **100**, 421; 1979), found at the heart of many nucleotide-binding enzymes (Riordan *et al. Science* **195**, 884; 1977). Tryptophan, on the cards for many years becuase of the nucleotide-dependent tryptophan fluorescence enhancement of skeletal muscle myosin (Werber *et al. Biochemistry*, **11**, 2872; 1972) seems less likely now in view of the absence of such effects in invertebrate myosins (Chantler & Szent-Gyorgyi *Biochemistry* **17**, 5440; 1978). Lysine, histidine and tyrosine have also been proposed. At last the opportunity to find out for certain is here. □

Ribonuclease still under attack

from Barry Robson

THE enzyme ribonuclease has always been popular with experimentalists seeking to understand the relations between chemical formulae, three-dimensional structures, and functions of protein molecules. Ribonuclease is a particularly attractive weak spot in nature's defences because it was the first enzyme to have its chemical formula determined (as a sequence of amino acid residues), one of the earliest enzymes to have its three-dimensional structure elucidated, and the first protein for which it was carefully demonstrated that the chemical formula alone determines the three-dimensional structure and function. It continues to be a prime target in a number of recent investigations.

One important approach to understanding the relationship between the chemical formula and the final structure is to attempt to follow how a protein molecule folds up after it has been unfolded. In particular, it would be of interest to know how a protein folds up so rapidly: the current theory is that it is rapidly directed towards the native structure by a process of nucleation in which certain structural features such as α-helices and β-pleated sheets form first, propagating further structure around them. By tritiating the exchangeable amide protons of unfolded RNase A and following exchange of tritium with the surrounding solvent during refolding, Schmid and Baldwin (*J. molec. Biol.* **135**, 199; 1979) have been able to confirm that the protein does fold up by a stepwise process, early stages being hydrogen bonded structures in which the tritium is protected from exchange. Since α-helices and β-pleated sheets are such structures, this would seem at first consideration to support the nucleation model. In particular, it supports the idea that such intermediate structures are metastable, possibly in appropriate conditions stable, and form relatively rapidly, as suggested previously by studies on penicillinase using more standard techniques (Robson & Pain *Biochem. J.* **155**, 325; 1976).

However, the nucleation idea is complicated by the experimental observations that the stability of the intermediate structure depends on interactions with the rest of the protein. In their case Schmid and Baldwin find that an artificially cleaved-off fragment of ribonuclease known as the S-peptide seems to be essential for the stability of the intermediates. In a further detailed study Labhardt and Baldwin (*J. molec. Biol.* **135**, 231 and 245; 1979) observed (1) that S protein (ribonuclease A without S-peptide) folds up some hundred times more slowly than intact ribonuclease A, and (2) that on adding S-peptide to S-protein, the combination of S-peptide and S-protein occurred at an intermediate stage, rather than at the end of the folding process. Labhardt and Baldwin exclude the model for protein folding in which there is an initial slow diffusion of the molecular conformation into a restricted range of three-dimensional structures, and demonstrate instead successive folding stages with rates dependent on the stabilities of intermediates from preceding steps. Whether this supports or excludes the classical model for nucleation depends on how one interprets that model. Rightly or wrongly, many workers seem to associate the idea of nucleation with a key directing step, the question of rates being one of their own preference. That Labhardt and Baldwin are more proper about the definition of nucleation is, however, irrelevant, since they provide a self-consistent and meaningful description of the folding process.

Baldwin and colleagues also give considerable attention to the fast and slow folding species of RNase in their studies. In this they accept the current interpretation that the slower species is the product of a kind of isomerisation of proline residues in the unfolded form. This may, however, be a case in which attention to one enzyme is less satisfactory. The interpretation in terms of isomerisation is best tested by reference to the different rates of folding kinetics of many different proteins, correlating the proline content with those rates (Stellwagen *J. molec. Biol.* **135**, 217; 1979).

Studies of this type provide a logical framework for the theoreticians, whose principal goal is to predict the three-dimensional structure of a protein from its amino acid sequence alone, and ultimately to design new proteins by chosing the amino acid sequence to give the required conformation and function. A major difficulty here is that many amino acid residues considered alone have only a subtle effect on the overall conformation of the molecule: all the amino acid residues tend to interact in a complex way. The theoretician is faced with having to handle calculations concerning a delicate balance of forces and it is doubtful whether his armoury is as yet adequate to this task. Gutte, Daumingen and Wittscheiber (*Nature* **281**, 650; 1979) recently mounted an audacious rear attack on this problem by designing an artificial RNase of 34 residues, having chosen amino acid residues and their sequence which would seem likely to be a very strong generator of the conformation required. Particular emphasis was given to the strong tendencies of certain residues to form α-helix or β-pleated sheet. The philosophy was that the more subtle and ambiguous aspects should be avoided, and this rationale seems justified by their subsequent synthesis and investigation of the protein. Briefly, although a detailed analysis of the three-dimensional structure was not possible, the protein indeed had significant activity, particularly when in a dimerised form.

More precisely, one should say that the production of RNase activity may have been something of a bonus, since they state that their immediate aim was to produce a protein with nucleic acid binding ability. This is a necessary but not sufficient condition for RNase activity and it is conceivable that catalytic activity might have to have been introduced at a later stage by further refinement of the sequence. This turned out not to be the case, and it seems that their work brings the status of the theoretician's art one step nearer to practical application. However, noting that the activity of the artificial RNase was only a few per cent of natural RNase, one should consider appropriate control experiments. As Gutte *et al.* discussed, random amino acid sequences often have significant enzymic activities of various types. Perhaps it would have been helpful to compare the activity of their artificial RNase with that of random amino acid sequences of similar length and composition to establish the importance of specific consequences. If the histidine residue was responsible for the activity, then the precise environment may have been rather less important. Further, catalytic activity of another kind has been associated with a mere 10-residue sequence (Chakravarty *et al. Experientia* **29**, 786; 1973), so it does not follow that all of the artificial molecule was in the expected conformation. Particularly when the substrate is a macromolecule, this may itself be a source of the appropriate environment and conformational stability, involving a kind of 'induced fit' of the synthetic protein.

RNase and their relatives are among some of the smallest enzymes known and their ability to interact with nucleic acid makes them useful models both for modern and prebiotic systems of more general interest. Undoubtedly the recent studies will encourage the continued use of RNase and its synthetic analogues. □

Correction

In the article 'Probing the insulin receptor' (*News & Views* **282**, 11; 79) the incorrect impression may have inadvertently been given that the photolabelled probes used by C.C. Yip *et al.* were less well characterised than those of other groups. (line 4, paragraph 3, page 11). The probes are in fact specifically photolabelled at the B-29, A1-B29 or B1 positions, which was not stated in the article.

Post-receptoral processes in colour vision

from J.D. Mollon

ALTHOUGH our subjective experience of hue may seem endlessly varied, the process of colour vision begins with just three classes of retinal receptor, each sensitive to a large part of the visible spectrum. Long before these delicate structures could be directly measured by physiologists, the limitation to three parallel channels was deduced by psychophysicists — those who work out the logic of sensory systems from the responses of conscious observers to systematically varied inputs. More difficult for the psychophysicist was the task of discovering how absorption varied with wavelength for the individual classes of receptor, since these 'spectral sensitivities' overlap substantially and it is not possible to isolate, say, the short-wavelength receptors simply by stimulating the retina with violet light. However, experimental stratagems were developed to cause an observer's response to depend on signals from only one class of receptor: for example, the psychophysicist might use monochromatic adapting stimuli to suppress two of the three classes or he might choose spatial and temporal parameters for his target stimulus that were suspected to favour one class of receptor or he might seek observers genetically lacking either one or two of the three classes. For many decades, psychophysical estimates of the receptoral sensitivities differed widely, but the past 20 years have seen a quiet convergence on the wavelengths 440 nm (violet), 535 nm (green) and 565 nm (yellow green) for the peak sensitivities of the three classes; and although these values need correction for selective absorption in the media of the eye and although second-order disagreements remain, the psychophysical estimates are in first-order agreement with very recent physical measurements of individual receptors (see papers by Bowmaker and collaborators in *J. Physiol. Lond.*, **298**, 1980).

Isolating opponent channels

It is generally held that a second kind of parallelism follows the receptor stage. There are some channels (loosely called 'luminance' or 'non-opponent' channels and probably needing further subdivision) that receive signals of the same sign from the receptors with peak sensitivities at 535 and 565 nm, and there are others (the 'colour-opponent' channels) that receive antagonistic signals from different classes of receptor. The colour-opponent channels extract information about wavelength by comparing the relative absorption in different classes of receptor. (The receptors themselves, of course, are individually colour-blind, since they are broadly tuned and since a photon, once absorbed, yields the same signal whatever the wavelength of the stimulating light.)

Psychophysicists have developed stratagems to isolate individual channels at this second stage and several experimental techniques for isolating opponent channels became explicit at a meeting on post-receptoral processes held in London on 9 January by The Colour Group, an inter-disciplinary society linking those with physical, physiological, and aesthetic approaches to colour.

If detection thresholds are measured for weak monochromatic stimuli presented on various steady adapting fields, detection by opponent channels is favoured if the targets are of long duration or large area — presumably because these channels integrate in time and space more than do (some) non-opponent channels. Evidence for this position was presented at the meeting by E. King-Smith (University of Manchester) and by D.H. Foster (University of Keele).

King-Smith suggested that strong, white-adapting fields will adapt non-opponent more than opponent channels, because the sensitivity of the latter is controlled by the difference in signals from different receptors and so will change little with absolute light intensity. J. Mollon (Cambridge University) added the complementary suggestion that strongly coloured, monochromatic fields (as used classically by Stiles) cause detection to depend largely on non-opponent channels, because such fields disproportionately desensitise opponent channels.

Foster described a new technique for isolating opponent channels. On a standard adapting field is superimposed a small, steady 'auxiliary' field, which is congruent with the target flash. If, say, the target is of long wavelength and only the main adapting field is present, the field is most effective in reducing sensitivity when its wavelength is ~570 nm; introduction of the auxiliary field shifts the wavelength of maximal field sensitivity to ~610 nm, suggesting that detection now depends on a channel which receives excitatory signals from the 565-nm receptors and antagonistic signals from the 535-nm receptors. The effect of the auxiliary field is abolished if the auxiliary field is significantly larger than the target spot. Presumably the presence of a contour coincident with that of the target masks a spatial transient that would otherwise allow detection by a non-opponent channel.

Mollon proposed that detection will depend only on an opponent channel if the input signal is confined to the violet-sensitive receptors. Perhaps because the short-wavelength component of the retinal image is usually out of focus (owing to the chromatic aberration of the eye), signals from the violet-sensitive receptors seem to be used only to provide information about hue. Because these receptors are far removed in peak sensitivity from the other two classes, the sensitivity of the opponent channel can be modulated with long-wavelength fields without significantly changing the rate of photon absorptions in the violet-sensitive receptors themselves — a great experimental convenience.

According to a hypothesis of Pugh and Mollon (*Vision Res* **19**,293; 1979), an opponent channel is most sensitive to input perturbations when it is near the middle of its operating range. In collaboration with P.G. Polden and A. Stockman, Mollon has found large oscillations in sensitivity to violet targets during adaptation to a bright yellow field; these are thought to arise from changes in the balance of inputs to the opponent channel during bleaching of the long-wavelength receptors. King-Smith reported that in several ocular diseases (for example, retrobulbar neuritis and glaucoma) patients show a greater loss of sensitivity to short-wavelength targets when the eye is adapted to a yellow field than when the adapting field is white and relating this finding to the above hypothesis proposes that the operating range of opponent channels is reduced in disease.

It is well established that adaptation to a visually presented grating will briefly raise the threshold for a subsequently presented 'test' grating of similar orientation and spatial frequency. K. Ruddock (Imperial College, London) has previously reported that if the adapting and test gratings are presented to one eye, a low-frequency spatial pattern presented to the other eye during adaptation will reduce the extent of adaptation. V. Waterfield and he have now shown that the effectiveness of this contralateral stimulus depends on its wavelength. Moreover, variation of its actual pattern intriguingly reveals channels of different spectral sensitivities: thus a simple grating gives the photopic luminosity function, a pattern of blobs reveals a long-wavelength channel with opponent inputs from the 565-nm and 535-nm receptors, and the negative of the latter pattern gives a green-sensitive mechanism with a small inhibitory long-wavelength input.

Two possible pitfalls

Many papers in the recent literature have advanced a further stratagem for isolating colour-opponent channels: the observer is required to detect a spatial or temporal transition between stimuli that are of different wavelength but equal luminance. However, I feel that it is unlikely that this device will safely eliminate detection by 'luminance' channels. Suppose that the target is a red field briefly substituted for a white field of equal luminance. At the onset of the red field, an increment is presented to the 565-nm receptors and a decrement to the 535-nm receptors. We are

J.D. Mollon is at The Psychological Laboratory, University of Cambridge.

0028-0836/80/07623-02$01.00

obliged to adopt an assumption for which there is no proof, that the transient responses generated in the two classes of receptor will exactly cancel out in all the putative 'luminance' channels; we must suppose that the weightings of inputs from the different receptors are in a constant ratio for all channels and that the transient waveforms of different signs are symmetrical. Transients in space and time are biologically significant and it would be odd if the retina allowed them to be lost in this way.

A second pitfall may lie in relating the detection measurements mentioned above directly to the classical phenomenological measurements (see for example Hurvich & Jameson *Psychol. Rev.* **64,** 384; 1957) that kept alive the concept of opponent processes during a period of neglect. General understanding of the first stage of colour vision was earlier held back by a widespread but unjustified belief that the peak sensitivities of the three receptors should correspond to phenomenologically primary colours, red, green and blue; it may equally be a mistake to suppose now that the opponent processes of the retina must be directly related to the phenomenological oppositions of blue and yellow and of red and green. S. Zeki (University College, London) presented his measurements of the spectral sensitivities of individual nerve cells in Area V4 of the cerebral cortex of the rhesus monkey; even at this central level, although many cells have narrow bandwidths (10–20 nm), the peak sensitivities do not cluster very tightly at the four phenomenologically pure hues, blue, yellow, green and red, but are distributed throughout the spectrum, with possibly a gap at 560–570 nm.

Colour constancy

As we view an object from different distances and angles or under different illuminations, our perception changes much less than does our retinal image. This stability of our perception is known as perceptual constancy. It is an everyday observation that a sheet of white paper looks equally white in daylight and in the yellowish illumination of domestic tungsten light, although if outdoor film were used to photograph the paper indoors, the resulting transparency would have a strong yellow cast. The correction achieved by our visual system (but not by the photographic process) is called colour constancy. One of the most interesting results presented at the meeting was Zeki's finding that some individual cortical cells show colour constancy: if an array consisting of many different coloured patches is placed before a monkey, and, say, a green patch is arranged to cover the receptive field of a green-sensitive cell, the cell responds to the patch despite gross changes in the spectral composition of the illumination falling on the array; but the cell does not respond if, say, a red patch is placed in its receptive field and the overall illumination is adjusted so that the spectral composition of the flux reflected from the red patch was identical to the flux previously reflected from a green patch to which it did respond (Zeki *Nature* in the press). Under the latter condition, of course, the patch looks red, not green, to a human observer (see Land *Sci. Amer.* **237,** December; 1977) just as, in the classical demonstration of size constancy scaling, an after-image of fixed retinal dimensions looks of different sizes when projected on surfaces at different distances.

Colour preferences

The layman reasonably expects the colour scientist to be much concerned with people's colour preferences, but the experimental study of colour preference has an unhappy history of inconsistent results and has been neglected in recent years. Reviewing this field for the meeting, I.C. McManus (Bedford College and St. Mary's Hospital, London) noted that earlier studies had confounded variation in hue with variations in saturation and lightness, and he described a study, performed in Cambridge in collaboration with A. Jones and J. Cottrell, in which this failure was corrected. Another feature of this new study was the use of the 'method of paired comparisons': each of a large set of coloured chips was paired with every other chip and the subject was asked to express a preference between the members of each possible pair, thus allowing the experimenter to derive a measure of internal consistency. When saturation and lightness are held constant, the population shows a clear preference for blue and a clear dislike of yellow. Further analysis shows differences between individuals but consistency within an individual's data; differences between individuals seem to be almost entirely due to differences in lightness preference and saturation preference, with very small inter-subject differences in hue preference. ☐

THE CRAYFISH[1]

Common and lowly as most may think the crayfish, it is yet so full of wonders that the greatest naturalist may be puzzled to give a clear account of it." These words from von Rosenhof, who in 1755 contributed his share to our knowledge of the animal in question, are cited by Prof. Huxley in the preface to the careful account of the English crayfish and its immediate congeners, which forms the latest volume of the International Scientific Series. The book is not designed for "general readers," those somewhat luxurious but presumably intelligent persons for whom so much scientific knowledge is chopped and spiced at the present day. It is, as we gather from the author's statement, intended as an introduction to serious zoological study, for those who will turn over its pages, crayfish in hand, and carefully verify its statements as to details of structure with scalpel and microscope. To these and also to those who are already well versed in crustacean anatomy, the book will have great value and interest; to the latter more especially, as showing how in the careful study of one organism we are "brought face to face with all the great zoological questions which excite so lively an interest at the present day," and as an exhibition of that "method by which alone we can hope to attain to satisfactory answers of these questions."

REVIEW ARTICLE

Cellular site of opiate dependence

H. O. J. Collier

Miles Laboratories Limited, Stoke Poges, Slough SL2 4LY, UK

Experiments on whole animals, guinea pig isolated ileum, individual neurones in situ *and cultured neuroblastoma–glioma hybrid cells indicate that opiate dependence and associated tolerance develop within neurones bearing specific opiate receptors (opiate-sensitive neurones). The essential change appears to be an hypertrophy of the cyclic AMP system, in response to inhibition by opiate of a neuronal adenylate cyclase.*

CHRONIC treatment, either continuous or intermittent, of a mammal with an opiate drug produces tolerance, indicated by a lowered responsiveness to the drug, coupled with a dependence characterised by a heightened responsiveness to opiate antagonists and disturbance on withdrawal of drug. A basic requirement for understanding the molecular mechanism of this remarkable phenomenon is to identify the cellular site at which it happens. As long as the phenomenon was studied only in whole animals, as it was with few exceptions until quite recently, there was little opportunity of identifying its site, although some experiments pointed towards it. The recent development of methods of studying opiate dependence and tolerance in the myenteric plexus of guinea pig ileum, in individual neurones of the nervous system *in situ* and in cultures of cells of neural origin has made it possible to identify the main cellular site at which opiate dependence and associated tolerance occur. This article presents and discusses implications of the evidence that this phenomenon occurs within the opiate-sensitive neurone. In this discussion the term 'opioid' will be used to include both opiates, which are analgesic derivatives of opium, such as morphine, and synthetic or endogenous substances having similar actions.

Opiate-sensitive neurone

The opiate-sensitive neurone is one that possesses specific opiate receptors, of any variety. It can be characterised in three ways. First, interaction between opiate molecules and these receptors produces a change in the neurone that results in the agonist actions of the drug. Second, this interaction between opiate and receptor can be blocked by the pure opiate antagonist, naloxone[1]. Third, these actions are stereospecific, or perhaps more correctly, stereoselective, in that they are exerted by small does of only the (−) enantiomers of opiates or opiate antagonists.

Such actions of opiates contrast with their nonspecific actions, which are not antagonised by, and may be shared with, naloxone. Thus, both morphine and naloxone, being phenols, can act as cofactors for prostaglandin synthetase[2]. Again, both drugs inhibit hyperalgesia of rat paw elicited by intraplantar injection of prostaglandin E_2 (ref. 3). Non-stereospecific actions are produced by both the (+) and (−) enantiomers of opiates; for example, the same behavioural excitation is elicited by injecting either (+) or (−) morphine into the periaqueductal grey matter of rat brain[4]. This stimulatory action is not blocked by naloxone and is therefore also nonspecific.

Opiate-sensitive neurones exist in both the central nervous system (CNS) and the myenteric plexus. In the CNS, the action of opiates on the majority of these neurones is inhibitory; but a minority appears to be excited by opiates. For example, in a recent survey of the responses of individual neurones *in situ* in different areas of the rat brain[5], the opiate drug, normorphine, and the opioid peptides, β-endorphin and Met-enkephalin, inhibited nerve impulse production in the majority of responsive cells in the brainstem, cerebral cortex, caudate nucleus and thalamus; whereas each substance excited the hippocampal pyramidal cells. In the myenteric plexus, opiates inhibit the cholinergic neurone supplying the longitudinal muscle of the guinea pig ileum[6,7] whereas they stimulate a neurone supplying the circular muscle of the rat colon[8,9].

Tolerance or dependence is usually observed towards the specific inhibitory actions of opioids; but it has also been described towards their specific stimulatory actions, both in the CNS[10,11] and in the myenteric plexus[8,9]. Since the above experiments on pyramidal hippocampal cells were reported, however, evidence has been obtained that their apparently specific stimulation by opioid is in reality a disinhibition of the adjoining basket cell, which itself maintains a tonic inhibition of the pyramidal cell[12]. Possibly the other specific stimulatory actions of opioids also may eventually prove to be disinhibitions. Because of this, and because of the greater wealth of experimental data, only dependence and associated tolerance towards the inhibitory actions of opioids will be discussed below.

Before we enter this discussion, two principles should be noted. First, the response to binding of opiate molecules with specific receptors occurs at two rates–acute and subacute (or chronic). The acute response to a single dose may be assumed to begin immediately after the administered opiate has reached and bound with its receptor. The duration of the acute response can be measured in minutes. The subacute response to continued treatment, expressed as tolerance and dependence, is apparent within hours of treatment beginning. The duration of the subacute response has a briefer component, measurable in hours, and a longer component, measurable in days[13,14]. Very prolonged effects of chronic treatment have also been observed, but they are not included in the present discussion. Second, in experiments on tolerance and dependence, a fundamental principle of uncertainty operates[15]. Tolerance cannot be measured directly without administering drug, nor dependence without withdrawing it. Hence we cannot measure tolerance and dependence in the same preparation at the same time. Measurement of tolerance and dependence separately in parallel preparations, however, has led to general agreement that opiate dependence is accompanied by tolerance, although the extent of the decrease in responsiveness to opiate (tolerance) may be numerically less than that of the increase in responsiveness to opiate antagonist (dependence)[16].

Experiments in whole animals

Attempts to determine whether neurotransmitters were intimately involved in the mechanism of opiate dependence provided probably the earliest evidence on its cellular site, although their meaning was not clear to us at the time. In 1972, we showed that, in the dependent rat, naloxone elicited 10 behavioural signs of precipitated withdrawal, all of which were lessened or abolished by giving heroin shortly before naloxone

0028-0836/80/070625—05$01.00

challenge[17] (Table 1). In contrast to heroin, substances such as atropine, indomethacin and *para*-chlorophenylalanine, that block the action or formation of putative messengers between neurones, inhibited some signs of abstinence, intensified others and left still other signs unaffected. For example, atropine, given 30 min before withdrawal was precipitated by naloxone, significantly decreased the incidence of jumping, diarrhoea and chewing, but significantly increased that of irritability to touch and paw tremor, and left unchanged the incidence of teeth chattering, ptosis, head shakes and body shakes (Fig. 1). Essentially similar results were obtained when the withdrawal syndrome was modified with an inhibitor of the synthesis of serotonin or of prostaglandins. A simple and attractive explanation of these observations is that dependence in the whole animal occurs within neurones of the CNS that bear specific opiate receptors, and that other neurones with which these communicate are only secondarily affected.

Naloxone inhibits the induction of dependence, indicating that induction is specific, although a relatively high dose is needed[18]. That sensitivity to naloxone greatly increases in dependence[16,17,19] also accords with dependence occurring within the opiate-sensitive neurone, since the amount of naloxone required to precipitate withdrawal in dependent states is so low that the naloxone is presumably acting only at the opiate receptors on the neurones.

Table 1 Blockade by heroin, given before challenge, of morphine withdrawal signs elicited by naloxone challenge in dependent rats[17]

Withdrawal sign	No. of rats positive Saline	Heroin	Significance (P value)
Jumping	8	0	<0.001
Teeth chattering	10	1	<0.001
Irritable to touch	5	0	<0.02
Irritable to handling	10	1	<0.001
Diarrhoea	12	0	<0.001
Chewing	12	0	<0.001
Ptosis	11	4	<0.005
Body shakes	2	0	=0.24
Head shakes	5	1	=0.08
Paw tremor	3	0	=0.11

Twenty-four rats were made dependent by subcutaneous (s.c.) injection of 150 mg per kg of a sustained-release preparation of morphine; 23.5 h after this injection, 12 rats received heroin 40 mg per kg s.c. and 12 received saline; all rats were challenged 30 min later with naloxone 1.0 mg per kg s.c. Observers of the rat behaviour were unaware of what treatment each animal had received.

Myenteric plexus of guinea pig ileum

In the isolated ileum of the guinea pig, opiates inhibit contraction of the longitudinal muscle elicited by electrical stimulation of the post-ganglionic cholinergic neurone[1,6,7]. Continued exposure to opiate of the isolated ileum at 4 °C, 22 °C or 37 °C produces tolerance to this effect[7,20–23], and dependence, usually expressed as a contracture of the longitudinal muscle on challenge with naloxone[21–26]. As in the whole animal, tolerance and dependence thus induced in the isolated ileum are specific, in that induction is inhibited by naloxone[22,26]. Effects in the ileum are also stereospecific, in that tolerance and dependence are induced by the (−) but not by the (+) enantiomer of a pair of stereoisomeric opiates and that withdrawal contracture is elicited by (−) but not by (+) naloxone[22–26].

Three properties of dependence in the isolated ileum point towards its site. First, that the withdrawal contracture is blocked by hyoscine or atropine[21,23,26] places dependence within the myenteric plexus of neurones rather than in the longitudinal muscle. Second, that the ganglionic blocking drug, hexamethonium does not prevent the induction or expression of dependence[22,23,26] places dependence in the post-ganglionic region of the plexus, in which the opiate-sensitive neurones are present. Third, that responsiveness to naloxone increases both with duration of exposure to opiate and concentration of opiate used[26], until a very low concentration of naloxone is effective (Fig. 2), suggests, as already indicated, that the opiate-sensitive neurone is itself the site of dependence.

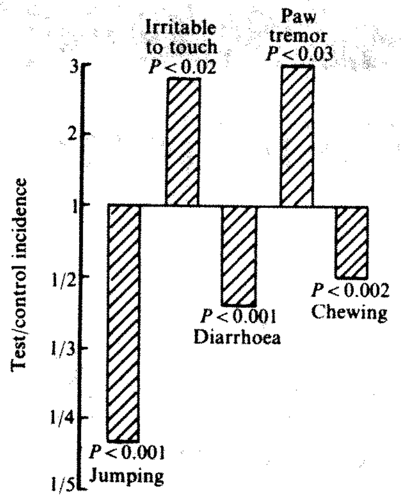

Fig. 1 Action of atropine on incidence of different withdrawal effects in morphine-dependent rats[17]. Withdrawal was precipitated by naloxone (1.0 mg per kg s.c.) 24 h after injection of a sustained-release suspension of morphine (150 mg per kg s.c.). Atropine (40 mg per kg s.c.) or 0.9% NaCl in water was given 30 min before naloxone. There were 32 test animals and 32 controls. The test/control incidence is the ratio of the incidence of the withdrawal effect in test and control groups. Atropine given before naloxone did not significantly change the incidence of teeth chattering, ptosis, body shakes or head shakes (Table 1).

Individual neurones *in situ*

Opiate tolerance and dependence have been studied in individual neurones *in situ*, in the sensorimotor cortex of the rat brain[27] and in the myenteric plexus of the guinea pig ileum[23]. In these studies, the action currents of nerve impulses were recorded by microelectrodes and drugs were applied by iontophoresis through micropipettes. Since neurones were used in which opiates inhibited the generation of nerve impulses and naloxone blocked the effect of opiates, these studies give direct information on tolerance and dependence in opiate-sensitive neurones.

In the sensorimotor cortex, continuous exposure to morphine for 40 min induced insensitivity to morphine, followed by a state of spontaneous excitation in the neurone that seems to represent dependence (Fig. 3). The inhibitory effect of morphine was also tested on cortical neurones stimulated with L-glutamate or acetylcholine in opiate-naive and opiate-dependent rats. Whereas 63 of 83 cortical cells tested were inhibited by morphine in the opiate-naive animals, only 1 in 50 was so inhibited in the dependent rats[27]. Thus, there is a high probability that tolerance occurs in the neurones that are normally inhibited by morphine. Since these tolerant neurones became excited when treated with naloxone, we can infer that they were dependent also.

Table 2 Cyclic AMP production by NG 108-15 cells cultured for 48 h in the absence or presence of morphine (10 μM)

Challenge solution	Cyclic AMP produced by cells cultured Without morphine	With morphine
Control	21	23
Naloxone	21	37
PGE$_1$	264	81
PGE$_1$ + naloxone	241	1,183
Adenosine	103	65
Adenosine + naloxone	72	217

After 48 h incubation, cells were challenged by incubation for a further 10 min with addition of 10 μM naloxone, PGE$_1$ or adenosine, as indicated. Cyclic AMP was then extracted and estimated in pmol per mg protein. Data from ref. 29.

In the myenteric plexus of guinea pig ileum, post-ganglionic neurones were made tolerant and dependent by incubation with morphine, normorphine or levorphanol for 24 h at room temperature, in the presence of hexamethonium and hyoscine[23]. In such neurones, administration of normorphine by microiontophoresis much less readily inhibited nerve impulse production than in control neurones (Fig. 4). In the absence of morphine, the neurone was spontaneously active, and, when treated with naloxone, the dependent neurones fired impulses at high frequency.

Neuroblastoma × glioma hybrid cells

There is no doubt that a certain line of neuroblastoma × glioma hybrid cells (NG 108-15 cells), cultured in the presence of an opiate, develop a form of tolerance and dependence, expressed as an increased capacity to produce cyclic AMP[28,29]. Table 2 illustrates this form of dependence, in which challenge with naloxone in the presence of PGE$_1$ generated five times as much cyclic AMP in cells cultured for 48 h in the presence of morphine as in those cultured in its absence.

Although these cells possess opiate receptors[30], and the affinity of opiates for these receptors is correlated with their ability to inhibit adenylate cyclase[31], the extent to which induction of tolerance and dependence in NG 108-15 cells resembles that in normal neurones is uncertain, for three reasons. First, although NG 108-15 cells put out long processes, they are not arranged in a stable intercommunicating system, as are neurones of the CNS or myenteric plexus. Each NG 108-15 cell must be regarded as a distinct unit, functionally resembling its neighbours. Second, the NG 108-15 cells are of malignant origin and, unlike normal neurones, they reproduce themselves. Thus, in 10% calf serum in their usual culture medium, the cells double their number in about three days[32]. These cells, however, can develop their characteristic tolerance and dependence even when their reproduction is inhibited (W. A. Klee, personal communication). The third difficulty is to translate a change in level of cyclic AMP in the NG 108-15 cell into terms of excitation or inhibition of normal opiate-sensitive neurones. The different effects of adenosine illustrate this difficulty. In NG 108-15 cells, adenosine stimulates adenylate cyclase (Table 2) and thus acts acutely in the opposite direction to morphine[29]. In contrast, in individual opiate-sensitive neurones of the corpus striatum of rat brain *in situ*, both adenosine and morphine, administered by microiontophoresis, inhibit nerve impulse production[33]. Moreover, in glial cells cultured from the brain of perinatal mice, adenosine binds with two distinct receptors[34]. One of these inhibits adenylate cyclase and lowers the level of cyclic AMP, the other has the opposite effect.

It is tempting to suppose that, in the opiate-sensitive neurones of the rat striatum, the receptor activated by adenosine is one that inhibits adenylate cyclase. If so, the observed inhibition by adenosine of nerve impulse production in the striatal neurone might express a decrease in cyclic AMP; and hence a rise in cyclic AMP in the NG 108-15 cell might be translated as excitation in the opiate-sensitive neurone. This interpretation would be consistent with the specific and stereospecific inhibition of adenylate cyclase exerted by opiates and opioid peptides in homogenates or slices of brain *in vitro*[35–42], although their potency against adenylate cyclase and the potency of naloxone in antagonising their action are usually lower than might be expected from the affinities for opiate receptor in brain homogenates[43–45]. Attempts have so far failed to show, however, that opiates acutely inhibit nerve impulse production in individual neurones of guinea pig myenteric plexus[46] or of cat spinal cord[47] *in situ* through an inhibition of adenylate cyclase.

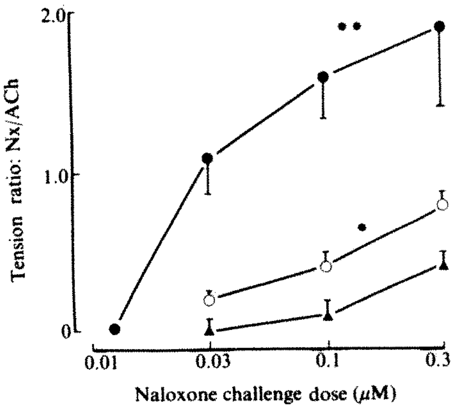

Fig. 2 Responses to naloxone challenge of segments of guinea pig ileum incubated for 24 h at 22 ± 2 °C in Krebs solution containing 70 μM hexamethonium (▲) or in this incubation medium, with the addition of 0.01 μM normorphine (○) or of 1.0 μM normorphine (●) (ref. 26). Tissues were set up for test at 37 °C in medium equivalent to that used for incubation and challenged 30 min later with naloxone (Nx). Tension ratio is the ratio of the maximal tension of contracture elicited by the challenge dose of Nx to that elicited bs a reference dose of 0.01 μM acetylcholine (ACh). *$P<0.01$, **$P<0.001$ for significance of difference of dose-response curve between normorphine-treated and control preparations.

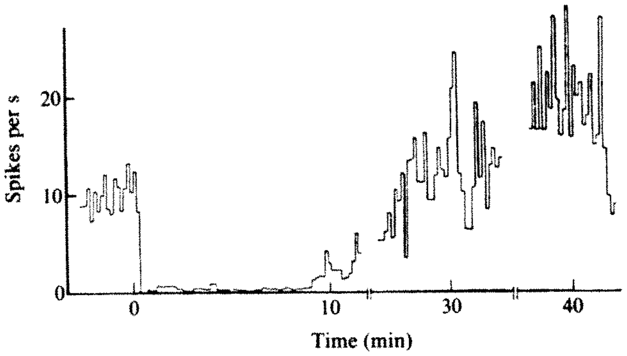

Fig. 3 Effect of prolonged application of morphine on frequency of nerve impulse production by a neurone *in situ* in the sensorimotor cortex of an opiate-naive rat[27]. Morphine was applied at 50 nA for 40 min from time zero. Breaks in the record are indicated by double vertical lines in the abscissa. For about 10 min, morphine suppressed nerve impulse production; thereafter production rose until, for the last part of the exposure to morphine, the neurone was producing impulses faster than it did before morphine.

Effects outside the neurone

The foregoing evidence shows that opiate dependence and associated tolerance can occur within the opiate-sensitive neurone; but it does not unequivocally indicate whether this neurone is their only site. That, as dependence deepens, preparations both *in vivo*[16,17,19] and *in vitro*[26] become responsive to very low concentrations of naloxone suggests that the opiate-sensitive neurone is also the primary and essential site of dependence.

There is, however, evidence that changes in other neurones may reinforce the effect in opiate-sensitive neurones. Thus, continued treatment of rats with morphine induces a supersensitivity to stimulation of adenylate cyclase by catecholamines in a cortical neurone downstream of that inhibited by opiate[48]. This supersensitivity is associated with an increase in postsynaptic receptors.

The opiate-sensitive neurone in a nervous system is necessarily subject to many influences from other neurones. Some of these could modify the induction or expression of dependence within the opiate-sensitive neurone. Such factors would include a diminished supply of endogenous opioid[49] or increased production of an endogenous opiate antagonist[50,51]. Since dependence can be induced, however, in the isolated ileum, these factors may be restricted in origin to cells in the neighbourhood of the opiate-sensitive neurone, or to the neurone itself.

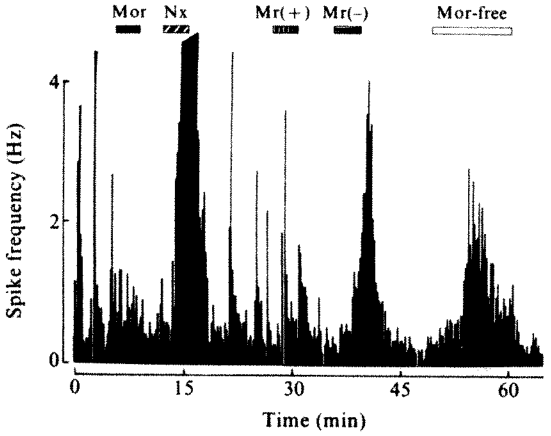

Fig. 4 Effect on a myenteric neurone of prolonged exposure to morphine in conditions of synaptic transmission blockade[23]. Before beginning the recording (time zero), this neurone had been exposed for 24 h to a solution containing morphine (1 μM), hyoscine (1 μM) and hexamethonium (300 μM). This solution continued to perfuse the tissue throughout the period of recording except for the time indicated by the open bar, when it contained only hyoscine and hexamethonium. During the periods indicated by the other bars, the perfusing solution contained additionally morphine (to a final concentration of 10 μM, Mor), naloxone (100 nM, Nx), Mr2267 (100 nM, Mr(+)) or Mr2266 (100 nM, Mr(−)). Note that the neurone was tolerant in that a very high concentration of morphine no longer depressed its firing. Naloxone caused a pronounced increase in firing (this reached 8–10 Hz), Mr2267 had no clear effect on the firing rate, but its active, (−) enantiomer, Mr2266 caused a marked excitation. This neurone was also excited simply by removing the morphine from the perfusing solution (Mor-free). In this and other experiments, second and subsequent exposures to antagonists did not cause as marked an excitation as did the first application.

Molecular mechanism of dependence

In the dependent neurone, the balance between excitation and inhibition has moved in favour of excitation. This is expressed both in an increased responsiveness to excitatory[52–54] and a decreased responsiveness to inhibitory[55,56] messenger substances. This change in balance seems to express an increased state of intrinsic excitation, shown by the high rate at which the dependent neurone fires nerve impulses either spontaneously or when challenged with naloxone (Figs 3 and 4). In the presence of such excitation, the growth of tolerance to endogenous opioid[49], possibly through induction of an enkephalinase[57], would be expressed as dependence.

This change in the balance of excitation may correspond with 'neuronal kindling' (ref. 25) or with 'supersensitivity' and 'subsensitivity' (refs 58, 59); but such terms do not provide a molecular mechanism for dependence. The principle that dependence occurs within the opiate-sensitive neurone enables us to discard several hypotheses of this mechanism and to retain for further consideration those concerning three aspects of neuronal function; (1) receptors for humoral messengers, whether opioid or non-opioid; (2) release of transmitter from the neurone terminal; and (3) second messenger systems connecting receptor binding and transmitter release. Although hypotheses, based on changes in receptors[4,25,59,60] or transmitter release[61,62], have been advanced, there is little supporting evidence. There is, however, strong evidence for a change in a second messenger system as the molecular mechanism of dependence. In theory, inhibition by opiate or other inhibitory substance of a process in a second messenger system could lead to tolerance and dependence, through a compensating hypertrophy in the system. This was first proposed for the cyclic AMP system[35], because opiates specifically and stereospecifically inhibited the E prostaglandin-stimulated adenylate cyclase of rat brain homogenate.

As we have seen, a compensating hypertrophy of cyclic AMP production in response to inhibition by opiate of adenylate cyclase has been clearly demonstrated in NG 108-15 cells[29]. There is evidence of four types that such hypertrophy also occurs in neurones of dependent animals. First, brain cyclic AMP production is raised in opiate withdrawal[63–68]. Second, injection of cyclic AMP into a cerebral ventricle of the dependent rat intensifies withdrawal jumping after naloxone challenge[69]. Third, withdrawal is accompanied by an increase in protein kinase activity in brain homogenates[68,70]. Lastly, a 'quasi-morphine withdrawal syndrome' indistinguishable in appearance from a true morphine withdrawal syndrome, can be elicited in opiate-naive rats by treatment with a potent phosphodiesterase inhibitor, such as 3-isobutyl-1-methylxanthine (IBMX), together with a low dose of naloxone[71,72]. The potency of phosphodiesterase inhibitors in eliciting this syndrome correlates with their potency as inhibitors of cyclic AMP phosphodiesterase in rat brain homogenate[73]. On the present evidence, therefore, an hypertrophy of the cyclic AMP system within the opiate-sensitive neurone in response to inhibition of adenylate cyclase emerges as the most likely explanation of opiate dependence.

Difficulties

Four seeming difficulties emerge from the above analysis. First, the extent to which sensitivity to morphine declines in the induction of tolerance and dependence is usually less than that to which sensitivity to naloxone increases[16]. Second, although naloxone is a potent antagonist of the acute actions of opiates[1], it rather weakly inhibits the induction of opiate dependence[18] or the inhibition by opiate of adenylate cyclase[35–42]. Third, in rat brain preparations *in vitro*, the potency of morphine as a specific inhibitor of adenylate cyclase[35–42] is usually less than might be expected from its affinity for the opiate receptor[43–45], although this does not apply to NG 108-15 cells[31]. Fourth, in individual neurones of the myenteric plexus or of the cat spinal cord, administration of neither cyclic AMP nor IBMX antagonised the acute inhibition by opiate of nerve impulse production[46,47], despite the evidence that opiates specifically inhibit adenylate cyclase in brain preparations *in vitro*[35–42].

These difficulties may disappear with continued experimentation. For example, although IBMX did not antagonise the acute inhibition by opiate of nerve impulse production in individual neurones of the myenteric plexus[46] or spinal cord[47], another methylxanthine, aminophylline, was recently found to do so in neurones of rat striatum[33]. If, however, the difficulties persist and sharpen, a second postulate may be needed. One possibility would be that a special variety of opiate receptor subserves dependence induction. Another would be that binding of opiate molecule with its receptor activates two distinct processes: one, the inhibition of adenylate cyclase that leads to dependence; the other, so far unidentified, leading to the acute agonist action. As usual, new insights raise new problems and require new experiments.

Climate and sea level in isotope stage 5: an East Antarctic ice surge at ∼95,000 BP?

John T. Hollin

Institute of Arctic and Alpine Research, University of Colorado, Boulder, Colorado 80309

Six high-resolution records correlated with marine isotope stage 5 suggest that substage 5c was essentially interglacial, and was terminated by a catastrophic cooling. Over sixty ^{230}Th dates indicate that the sea level in substage 5c rose to at least −2 m. Amino acid ratios, archaeology, pollen and lithostratigraphy suggest that the sea later jumped to about +16 m. The combination of the cooling and the large jump points to an East Antarctic ice surge, at ∼95 kyr BP.

BUDD AND MCINNES[1] suggest that "periodic surging of the large ice sheets may have been the rule rather than the exception". In Antarctica, Budd and McInnes envisage minor surges every 5 kyr or so, and major surges, such as those considered by Wilson[2], Hollin[3] and Flohn[4], every 100 kyr or so. I have pointed out that surging in Antarctica would have caused distinctive jumps of sea level: large, fast (a few hundred years or very much less?), brief (a few thousand years?), cool and, in the special case of Wilson's suggestion that surges caused the Pleistocene ice ages, late in each interglacial. I reviewed some lithostratigraphic and biostratigraphic evidence for such a jump late in the last interglacial, from below 0 m to about +16 m in stable areas. In 1972, impressed with the cooling events in Fig. 1*b*, *c*, *d*, and with the Mediterranean and Red Sea dates below, I estimated 95 kyr BP as the most likely date for this jump[5]. Later facing the evidence that the last interglacial *s.s.* was represented by marine oxygen isotope substage 5e and dated from about 125 kyr BP (ref. 6), I thought that if the jump was real it must date from roughly 120 or 115 kyr BP (ref. 7). I review here new evidence that the sea rose almost certainly to −2 m and probably to 16 m at about 95 kyr BP. Biostratigraphic evidence that the rise was late in 'the last interglacial' is explained by evidence that not only substage 5e but also 5c was essentially interglacial in character.

Climate

Figure 1*a* is an equatorial record of marine oxygen isotope stage 5. The global record of stage 5, based on nearly 100 cores, forms our best framework now for thinking about the last interglacial,

0028-0836/80/070629—05$01.00

s.l.[8]. However, in the marine isotope record, substage 5c usually appears more 'interstadial' than 'interglacial'; possible reasons are given later. Figure 1*b, c, d* show the Gulf of Mexico[9], Orgnac (France)[10] and Camp Century (Greenland)[11] rapid cooling events, whose interpretation as the result of an Antarctic ice surge has already been discussed[5]. Figure 1*e, f, g* come from high resolution pollen diagrams which appear to cover stage 5. Figure 1*e* is from the Tenagi-Philippon, Greece[12,13], where the oak forest of Wijmstra's zone S 'Drama', reflecting temperatures "a little lower than they are today", changed to cold steppe, reflecting "an average summer temperature at least 5–8 °C lower than today" (ref. 14) in one counting level, here estimated at <1,000 yr. Figure 1*f* is from Vandalia, Illinois[15]. If Grüger is correct in assigning his zone 1 to the 'Illinoian', that is, isotope stage 6, then the possible forest to prairie 'catastrophe' at the end of his zone 2c correlates very well with the coolings above. Figure 1*g* is from Woillard's[16] profile from Grand Pile, France, in which she recognises three distinct interglacials in stage 5 time. Her St Germain I interglacial correlates with substage 5c, but in this case its exact position on the horizontal axis was uncertain. The deforestation at 1,380 cm seemed much higher in the profile than the initial deterioration in the detailed diagram of the vegetation. In Fig. 1, I considered the most important climatic break was at about 1,460 cm (where the still high *Carpinus* pollen would match that in the massive brickearth at West Thurrock, UK below[7]). Now Woillard has reported[17] that there was indeed an abrupt vegetational and climatic break at 1,455 cm.

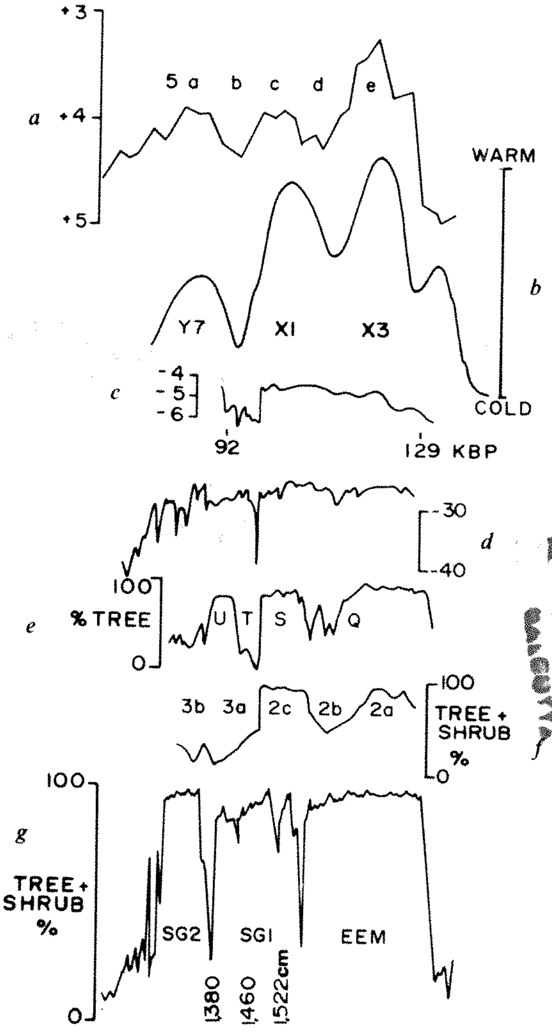

Fig. 1 Correlations with marine oxygen isotope stage 5. *a*, Isotope substages 5a–e in core V19-29 from east equatorial Pacific[8]. Scale on left is isotope composition of benthic foraminifera in ‰. *b*, Biological climatic curve from western Gulf of Mexico[9]. Y7 and so on are foram zones. *c*, Isotopic curve from Orgnac stalagmite, France[10] in ‰. Numbers below are ^{230}Th age determinations. *d*, Isotopic profile from Camp Century ice core, Greenland[11] in ‰. *e*, Pollen diagram from the Tenagi-Philippon, Greece[12,13]. U and so on are pollen zones. *f*, Pollen diagram from Vandalia, Illinois[15]. 3b and so on are pollen zones. g, Pollen diagram from Grand Pile, France[16]. SG2 and so on are Woillard's St Germain II and I and Eemian interglacials. Numbers below are depths in cm.

Two important points emerge from Fig. 1. First, except in Fig. 1*a*, it seems that the substage 5c climate was essentially interglacial at the localities discussed. This shows clearly in the physical evidence from Orgnac and Camp Century, is implied by Grüger for his zone 2c and is argued specifically by Woillard[18] for her St Germain I. Two North American speleothem records suggest that substage 5c was actually warmer than 5e (ref. 19). Proglacial meltwater lakes in Antarctica were particularly widespread in 5c time (ref. 20, p. 182, Fig. 4). I avoid defining 'interglacial', and do not think that substage 5c was as warm as 5e in every part of the globe, but in view of the evidence above it is not surprising that the sea in substage 5c rose slowly to within 2 m or so of its present level. Second, in all six of the high resolution records, it seems that substage 5c was terminated by a 'catastrophic' cooling. At Camp Century, where the time resolution is best, the cooling may have occurred in <100 yr.

Sea level

That the Gulf of Mexico cooling precedes a prominent ash deposit there, makes an Antarctic surge rather than a volcanic outbreak the most probable cause of these possible coolings[5,21]. In any case, this particular cause is subject to the sea-level test. Traditionally (see, for example, refs 22–26) two sea levels—at 6–8 and 15–20 m—are assigned to the last interglacial in stable areas away from, for example, plate boundaries and the Pleistocene ice sheets. In the past 15 yr over sixty ^{230}Th/^{234}U dates have been obtained from geomorphological features, chiefly reefs and notches, at the 6–8 m level, notably in the Pacific and Indian oceans[27] and in detailed studies in Aldabra[28], Oahu[29] and the Bahamas[30]. The mean of these dates is 125 kyr BP, so that the 6–8 m level seems to be from early in the last interglacial. The 15–20 m level is less pronounced geomorphologically, and has been neglected in dating studies: does it really belong to stage 5, or is it from an earlier interglacial? On the basis of its associations with Mousterian archaeology and cool molluscs, many early authors attributed it to the end of the last interglacial and the beginning of the last glaciation (ref. 31, pages 1256, 1271). In 1965 I suggested that such a high late level might be explained glacio–eustatically by an Antarctic ice surge[3]. I now consider the evidence for this hypothesis which leads to the sea-level scheme of Fig. 2*a*.

The classical area for the study of Pleistocene sea levels has been the western Mediterranean and Morocco. Work beginning in the nineteenth century was reviewed by Osborn and Reeds[32], who called the correlation of a 20–18 m shoreline, a Mousterian archaeology and the early Würm glaciation "the most firmly established of any". In this area, Stearns and Thurber[33,34] conducted a pioneering ^{230}Th dating campaign on molluscs. Ten of their results fell between 140 and 115 kyr BP and 10 between 95 and 75 kyr BP. Of their dates for which elevations are given, the mean for the three shells in the older group is 6.5 m, and for the five in the younger is 11 m. Even if their young sample L934E from 33 m is omitted, the mean for the remaining four is still 5 m. Young sample L787D from 10 m comes from a conglomeratic apron reaching above 18 m. Obviously, these results favour early schemes and the present paper. However, there are two criticisms.

First, Kaufman *et al.*[35] concluded that the ^{230}Th method on individual molluscs was giving correct ages no more than half the time. But, as the 140–115 kyr BP group fits very well the 125 kyr BP mean of so many coral dates, it seems likely that the 95–75 kyr BP group also corresponds to some real event, and concentrations of dates in this range continue to be obtained from the Mediterranean[36]. Especially important are the results of Bernat *et al.*[37] from Spain, where seven *Strombus* molluscs yielded a mean age of 97 kyr BP, with a standard deviation of only 4,900 yr. Sanlaville[38] describes a double transgression to 10 m in the Lebanon, associated with two mollusc dates of 90 kyr BP, and with archaeology from *le premier interstade würmien*. Second, the Mediterranean is a plate boundary area, and Hey[39], for example, has stressed the impersistence of many of its raised shorelines. However, Gigout *et al.*[40,41] claim that in the area of Bernat's dates, the lowest raised strandline can be traced for 400 of the 1,100 km they studied. We need more work in stable areas but, to test the surge hypothesis, it should be sufficient to see if the 95 kyr BP transgression was relatively higher than the 125 kyr BP.

Table 1 Summary list of ^{230}Th/^{234}U dates suggesting a substage 5c sea level at −2 m or above

Area	No.*	Dates (kyr BP)	Sea level (m)	Refs
Western Mediterranean, Morocco	10 M	95 to 75	18?	33, 34
Algeria	3 M	102, 93, 90		36

* M, molluscs; C, corals; S, solitary corals.

† Last four areas are not discussed in the text, but merit study.

In the UK, I have summarised[7] much evidence for a double sea level in the last, 'Ipswichian' interglacial: an early, 7-m level represented in the Thames estuary by brackish plants at Ilford, an inferred floodplain surface at Aveley, and tidally laminated beds at Crayford; and a late, 16-m level represented by a polleniferous aggradation at Aveley and West Thurrock, by Hodgson's sand and gravel sheet in Sussex, continuous from 0 to 14 m, and by the raised beach at Portland, rising to 20 m, and with modern but cool molluscs. Kidson[42] suggests a double last interglacial sea level in Somerset, at 6–9.5 then 18–20 m, the later higher level represented by the Burtle Beds. Bowen[43] has long argued for a double level in Wales.

Recently, Miller *et al.*[44] reported an amino acid, relative dating campaign in the Thames estuary: modern D-alloisoleucine: L-isoleucine ratios (total, = free plus peptide-bound) are close to zero. Ratios from the freshwater mollusc *Corbicula fluminalis*, from Ilford, Aveley and Crayford above, fell into a well defined group with a mean of 0.21. Andrews *et al.*[45] reported on a similar study on coastal exposures. Ratios from the marine mollusc *Patella vulgata*, from Portland and the Burtle Beds, had a mean of about 0.12. The marine *Macoma balthica* from the Burtle Beds had a mean of 0.14. The small *Patella–Macoma* difference may be a species effect. But the large difference between *Corbicula* and these shells suggests that the latter may indeed be appreciably younger, especially as at the one locality where it is possible to compare the freshwater and marine ratios (Selsey–Selsea Bill; ref. 44, Tables 1, 2), four *Corbicula* all have ratios less than one *Macoma*.

An early 7-m level in the UK would correlate very well with the global 125 kyr BP, substage 5e level; is there any evidence that a late 17-m level could be from a substage 5c interglacial? Sutcliffe has argued that the UK Ipswichian was at least twofold (see ref. 46, pages 223–224 for references and discussion). He claims that the mammals at Trafalgar Square, in particular *Hippopotamus amphibius*, show it to be from a younger interglacial than Ilford, Aveley and Crayford above. I have recently realised that *Corbicula* is missing from just those two Thames sites, Trafalgar Square and West Thurrock[7], with *Hippopotamus*. In fact, a literature check has revealed no UK site where these two fluvial animals undoubtedly lived together. For example, there is no overlap between the seven sites in Sparks's[47] review of the last interglacial *Corbicula* and the four in Stuart's[46] review of last interglacial *Hippopotamus*. A third biological argument for multiplying the Ipswichian is provided by the contrast between the beetles from Aveley and the more exotic ones at Trafalgar Square (and Bobbitshole, Ipswich)[48]. Woillard's[16] diagram from Grand Pile suggests that it may be difficult to distinguish 5e and 5c interglacials by the pollen method, but Ilford and Aveley, Trafalgar Square and West Thurrock, plus the coastal sections should clearly be the subject of a further amino acid study.

A difficulty with this multiplication is that, if the *Corbicula* from Ilford, Aveley, Crayford (and Stutton[7,44]) are from substage 5e, how can the massive brickearth at these localities[7] be attributed to a surge in substage 5c? The recent pollen work of Woillard[17], plus the sea-level observations of Chappell and Thom[49], raise the possiblity of another (minor?) surge at the end of 5e also (Fig. 2*a*). (Rough calculations of the ensuing ice build-up rate in Antarctica (ref. 7, p 49) and perhaps the north suggest that a surge high sea stand probably lasted longer than Chappell and Thom assumed). If the resulting transgression rose to <16 m, its littoral deposits would have been largely destroyed by the apparently major, 5c transgression that is the main concern of this article.

In northern France, Lower Normannian (up to 5 m) and Upper Normannian (12–18 m) beaches have traditionally been assigned to the last interglacial. Guilcher[50] writes "it may be that the Lower Normannian is older in some areas". In northern Europe, Charlesworth (ref. 31, p 959) reviews a large amount of evidence for a double sea level in the last interglacial. The second, 'Portlandia Sea', 'White Sea' transgression contains the *Carpinus* typical of the second halves of the Eemian and St Germain I interglacials. Van der Heide[51] writes of the White Sea area "two transgressions are known. The first has a molluscan

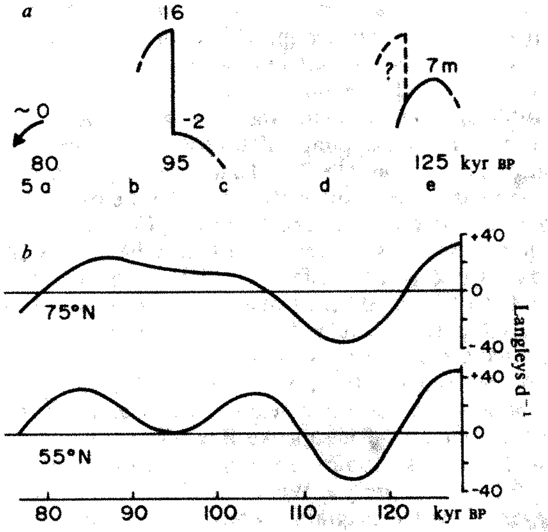

Fig. 2 *a*, Sea-level scheme for isotope stage 5, showing suggested major surge at about 95 kyr BP and possible minor surge at about 120 kyr BP. Figures above curves are elevations in m. 5a–e are correlations with isotopic substages. *b*, Deviations of solar radiation from their 1950 AD values, for the caloric Northern Hemisphere summer, for 75° N and 55° N, plotted from ref. 85, Table B.

fauna including somewhat warmer elements. The fauna of the second is markedly colder. Several authors believe that a connection between the White Sea and the Baltic Sea originated during this transgression". In the Black Sea, on the Caucasus coast, Muratov *et al.* (ref. 52, Table 1) assign to the Riss-Würm, Mikulino interglacial a double 'Karangat' transgression, to 5 then 10–15 m, associated with mollusc dates of 88–66 kyr BP.

In the Red Sea, Veeh and Giegengack[53] review several mollusc dates in the 90 kyr BP range, and report their own dates of 92, 89, 89 and 70 kyr BP from corals up to 8 m in Egypt. Battistini *et al.*[54] report coral dates of 94 kyr BP at 0 m and 85 kyr BP at 1 m from the area of Madagascar. From South Africa, near Port Elizabeth, Davies[55] reports that "Amino acid ... ratios in molluscs ... indicate that a transgression to +15 m occurred after a sea level at +8–9 m that is presumed to be Eemian in age on a variety of evidence. The transgression may be ... from a surge of the ... Antarctic ice sheet."

In Australia, in New South Wales, coral dates between 143 and 112 kyr BP are assigned to a sea stand at 5 ± 1 m (ref. 56). But in Victoria, Schornick[57] has reported eight mollusc dates with a mean of only 101 ± 14 kyr BP. Outside New South Wales, the sea level in the last interglacial is thought to have been much higher; 21 m in Victoria[58] and 21 m by many workers in Bass Strait and Tasmania[59]. As in Sussex above, the deposits involved seem to be unbroken down to below 0 m. That this level is slightly higher in Australia than elsewhere is what we might expect if the source of the water involved was (West or East) Antarctica (ref. 60, Fig. 4).

Table 2 Summary of data suggesting a stage 5 sea level at ~16 m

Area	Principal evidence	Refs
Western Mediterranean	Archaeology, ^{230}Th dates	32–34
UK	Lithostratigraphy, pollen, amino acid ratios	7, 42, 44, 45
Black Sea	^{230}Th dates	52
South Africa	Amino acid ratios	55
Australia	Lithostratigraphy	58, 59
Virginia	Lithostratigraphy, amino acid ratios	65, 67
Bermuda	Lithostratigraphy	70

In the Pacific, Bernat *et al.*[61] report from New Caledonia and the Loyalty Islands four coral dates with a mean of 122 ± 3 kyr BP and six with a mean of 95 ± 4 kyr BP. Most of their samples were recrystallised, but the two with 100% aragonite came from the younger group. This area is close to a plate boundary, and the only island on which it is possible to compare elevations is Lifou. There, three of the older dates seem to come from within an old reef or cliff (the substage 5e one?), raised to about 11 m. One of the younger dates comes from the surface of the platform below this, at ~2 m. To test the surge hypothesis, it would be good to date more surface samples, below and especially above 11 m. In Japan, Kikuchi (ref. 62, Fig. 11) and Naruse have deduced double sea levels above 0 m in the last interglacial. Machida[63], working with fission track dates, estimated absolute sea levels at 100 and 80 kyr BP at about −9 to −3 m. Hopkins[64] deduced a double sea level in the last interglacial in Alaska, but thought that the early level was higher.

Marine deposits on the east coast of the US have been the subject of an extensive amino acid study by Belknap[65]; his Fig. 44, on the Delmarva–Chesapeake Bay region, shows concentrations of dates at about 125 and 95 kyr BP (although the intervening unconformity at Wailes Bluff does not fit easily into Thompson's[66] pollen diagram). Many of these dates are from coastal exposures, and it seems likely that most of the shells from the thin, landward edges of the marine formations have been leached away. However, intensive lithostratigraphic work on the extent of these formations in Virginia was carried out by Oaks and Coch[67]. They assigned to the last interglacial a Great Bridge Formation, related to a sea stand at about −2 m, which was followed by an unusually rapid transgression to a Norfolk Formation level at 14 m. The sea then regressed below 0 m, leaving the deposits of the Kempsville, Londonbridge and Sand Bridge Formations. Five amino acid dates between 100 and 91 kyr BP seem to come from the Norfolk Formation. On the other hand, 11 solitary corals from the Norfolk and Kempsville Formations have a mean ^{230}Th age of only 68 ± 9 kyr BP (ref. 65, appendix G). Whether this discrepancy has a geological or a chemical origin remains to be discovered. In Florida, coral dates include one of 95 ± 9 kyr BP from the Key Largo Limestone at Windley Key[68].

In the Bahamas (ref, 30, Table 2), perhaps the coral conglomerates dated to 103, 105, 94 add 112 kyr BP are reworked from a primary substage 5c sea stand. In Bermuda, Land *et al.*[69] recognised a sea-level maximum of 5 m at 120 kyr BP (four dates), then a regression to below 0 m, then a transgression to between 11 and 20 m, dated, however, to 130 kyr BP. Vacher[70] studied this second transgression more closely; he concluded that it was preceded by a sea level "slightly below present datum", that it reached 15 m and, from lithostratigraphic evidence, that it was "abrupt and rapid, and may signify a catastrophic surge in Antarctica". Harmon *et al.*[71] confirmed the 120 kyr BP dating (mean of seven dates 124 ± 6 kyr BP), deduced a regression to −8 m or below then a second transgression at −6 m at about 100 kyr BP, redated the 130 kyr BP coral four times, and obtained a mean age of 97 ± 9 kyr BP for it. All these results fit Fig. 2*a* well. However, whereas the evidence for the 15-m sea level comes from seaward dipping calcarenites on the Bermuda north shore, the 97-kyr BP coral came from the south shore, from a deposit which Harmon *et al.* interpret merely as a storm beach, thrown up from a sea stand at about 0 m. Against any higher rise is the absence of any aragonitic, marine overgrowth on their speleothem 73018, from about 7 m and dating from 162 kyr BP. But perhaps this speleothem was protected against a brief transgression by the freshwater table. We need now some dates from the north shore calcarenites. However, in the surge hypothesis, these beds may represent, not conventional marine deposits, but rather the rapidly reworked, semi-consolidated terrestrial deposits and fossils from the 125–95 kyr BP regression: like the West Thurrock brickearth, a possible diluvium[7].

Discussion

The ^{230}Th dates above (Table 1) strongly suggest that sea level in substage 5c rose to at least −2 m. Many of the mollusc dates, plus the amino acid ratios, archaeology, pollen and lithostratigraphy (Table 2) suggest that the sea later rose to ~16 m. The data from Sussex, Portland and the White Sea suggest that the later rise was cool. Thames, Virginia and Bermuda authors have all argued that it was rapid. Unusually rapid rises to 15 m have been argued for Guernsey[72] and Cyrenaica (ref. 73, p 54), although here no dating is available. Obviously, these data support the surge hypothesis. However, they also raise several questions.

(1) An immediate worry with Fig. 2 is the great size of the sea level jump: 18 m. The present distribution of the world's ice, in terms of sea-level equivalents, is roughly: East Antarctic ice sheet 60 m, West Antarctic ice sheet 6 m, Greenland ice sheet 6 m, lesser ice caps and valley glaciers 0.3 m. If the jump is real, then it requires a surge, or ungrounding (ref. 74, p 185), of the world's thickest ice, most probably from Wilkes Land, less probably from Queen Maud Land (see ref. 75 for bedrock and ice thickness maps).

(2) Veeh[27] puzzled why little trace of Stearns and Thurber's younger dates appeared in his coral study. We see now that the primary 5c reef, at ~−2 m, is out of sight today in stable areas. And the secondary, surge transgression would have been too rapid for reef growth, and would be marked chiefly by a sheet or patches of sand, with relatively cool molluscs. However, as the water cleared, and the initial cooling waned, some coral growth would have recommenced in low latitudes, and this is perhaps what we see in the Red Sea, Madagascar, and so on.

(3) Many workers remark that their elevations do not fit 'the Barbados model' (ref. 76), of 122, 103 and 82 kyr BP sea stands at +6, −13 and −13 m respectively. But Stearns[77] re-evaluated the Barbados (and New Guinea[78]) elevation data, and concluded that the 103 and 82 kyr BP stands were in fact close to 0 m. The present data strongly support him. In a third uplifted area, in Atauro (ref. 79, Fig. 9), if reef terrace 1b in fact continued developing until 95 kyr BP it would reflect an absolute elevation not far below the −2 m given here.

(4) The Barbados model gained support from an early foraminiferal oxygen isotope study[80], which suggested a substage 5c stand at about −13 m. Subsequently, Barbados mollusc isotope data have suggested a 5c stand at −28 m, and Barbados coral isotope data a 5c stand at −43 m (ref. 81). Perhaps these disagreements can be resolved by interpreting the isotopic data more in terms of temperature than ice volume. The mean isotopic change, from substage 5e to 5c, involved in the results above was about +0.4‰. In the present scheme, the sea dropped from +7 to only −2 m in this time, so we can attribute only +0.1‰ of the change to an ice volume effect[8]. The remaining +0.3‰ may represent a small cooling, which we may calculated[82] as 1.3 °C. Such a cooling in this area is indeed suggested by Kennett and Huddlestun's planktonic biological data, in Fig. 1*b*.

(5) An even lower substage 5c stand is suggested by the 5e to 5c change of +0.7‰ in the benthic isotopes of Fig. 1*a*. This disagreement between stage 5 sea levels and the benthic isotope data has already been discussed, by Broecker[83]. Again, he suggests a cooling, by about 2 °C, late in substage 5e. He draws attention to a possible analogous benthic change of over +0.2‰ late in the Holocene stage 1, a change which obviously cannot be interpreted in terms of ice volume.

(6) The emphasis here has been on finding out if Antarctic surges do in fact happen, and it may be premature to discuss their possible role in the spectrum of climatic change[2,84]. However, one climatic point may be made. Not only a catastrophic cooling at the end of 5c, but also the whole of the subsequent cold substage 5b is hard to explain by insolation changes. During 5b time summer insolation north of 55° N was greater than today's, and north of 75° N was continually increasing (Fig. 2*b*). Substage 5b seems to be an ice age that is better explained by a surge than by insolation changes. Hitherto, cold substage 5d may have seemed a case of the opposite (Fig. 2), but now, in the light of refs 1, 17 and 49, and of the possibility of a minor surge at ~120 kyr BP, this no longer seems certain.

The sea-level scheme of Fig. 2 incorporates a very large quantity of data. We now need more quality. Above all, we need ^{230}Th coral dates up towards 16 m in stable areas, although care must be taken to distinguish the possibly thin and patchy deposits of a surge from the older deposits and geomorphology beneath. It is just possible that the uppermost littoral deposits at 16 m are the results of the minor, substage 5e (120 kyr BP) surge suggested above, but most of the present evidence favours their attribution to a major, 5c, 95 kyr BP surge. If the surge hypothesis is wrong, its disproof could come deposits at about 10 m that remained continuously freshwater after 125 kyr BP (see refs 3 and 5, and Bermuda speleothem 73018 above).

Completion of this paper was made possible by a NRC Senior Associateship with NOAA Boulder, where I thank J. O. Fletcher and H. Weickmann for much assistance. I acknowledge support from the Department of Energy through NSF grant ATM-7826688, support from INSTARR, and permission from J. T. Andrews *et al.*[45] to use unpublished data.

Enriched mantle: Nd and Sr isotopes in diopsides from kimberlite nodules

Martin Menzies & V. Rama Murthy

Department of Geology and Geophysics, 108 Pillsbury Hall, University of Minnesota, Minneapolis, Minnesota 55455

Nd and Sr isotope compositions of diopsides from micaceous garnet lherzolite nodules found in kimberlite pipes at Bultfontein and Kimberley, South Africa are reported. The diopside data extend the mantle array, as defined by uncontaminated oceanic and continental basalts, to radiogenic $^{87}Sr/^{86}Sr$ *values. These data are used to demonstrate the ancient enriched, grossly heterogeneous nature of the sub-continental mantle, which complements the predominantly depleted nature of the sub-oceanic mantle.*

THE chemical character of the sub-continental mantle is the subject of considerable speculation. Most of our knowledge comes from heat flow and seismic data[1,2] or analysis of mantle-derived materials. Thermal and seismic studies point to a continental mantle more depleted in magmatophile elements than the sub-oceanic mantle[2]. Yet one of the principal conclusions from the interpretation of continental basalt data is that the continental lithosphere is essentially undepleted[3] in the light rare earth elements (REE). However, note that interpretation of the Sr and Nd isotope geochemistry of continental volcanic rocks is severely hampered by uncertainties concerning contamination by crustal material[4,5]. Thus considerable controversy has arisen over the extent of contamination and whether or not the range in isotopic composition reflects source heterogeneity[3] or variable degrees of crustal assimilation[4,5]. Recent interpretations of Rb–Sr isotope geochemistry assume that contamination effects are negligible[3] but combined Nd- and Sr-isotope studies have elegantly demonstrated 'selective' contamination of basalts with crustal granulites and amphibolites. To alleviate these problems one can study peridotite nodules believed to be of mantle origin. However, care must be taken as minor amounts of contamination undoubtedly occurred during or after transportation of the mantle fragments to the surface. For example, recent isotopic studies of alpine peridotites have shown profound alteration during and after obduction[6]. Similarly, alkali basalt nodules are occasionally contaminated by the host basalt and some kimberlite nodules may have been 'metasomatised' by the host kimberlite[7,8]. To eliminate any possibility of such contamination recent isotopic and trace elements studies[6,9] have concentrated on carefully separated, inclusion free, mineral separates.

Diopside separates from these garnet lherzolites were chosen for analysis here because of their favourable abundances of Nd (20–50 p.p.m.) and Sr (150–400 p.p.m.), and the low Sm/Nd ratios (0.05–0.10), as well as the low Rb/Sr ratios (Table 1).

The analytical procedures used in this laboratory for Nd and Sr isotopes have been described elsewhere[10,11]. Separation and purification procedures for the mineral fractions have also been outlined previously[6,12].

Nd and Sr isotopes in mantle diopsides

The Nd- and Sr-isotope compositions have been measured in diopsides for eight lherzolite nodules and the Nd isotopic composition in diopside from a ninth nodule (Table 1, Figs 1 and 2). The diopsides have a considerable range in $^{87}Sr/^{86}Sr = 0.70465–0.70752$ and a similarly large range in $^{143}Nd/^{144}Nd = 0.51257–0.51195$. The $^{87}Sr/^{86}Sr$ ratio of co-existing garnet was measured in one nodule and was found to be identical to the co-existing diopside (Table 1). Secondary micas found in two nodules have radiogenic $^{87}Sr/^{86}Sr$ ratios and low $^{143}Nd/^{144}Nd$ ratios (Table 1). The abundance of mica in these nodules can present a severe contamination problem due to the high Sr content (~500 p.p.m.). However, minute inclusions of mica in diopside would tend to produce a linear relationship between Sr content and $^{87}Sr/^{86}Sr$. This was not found to be the case and, furthermore, each diopside was carefully handpicked and inspected for adhering mica flakes or inclusions. The identical $^{87}Sr/^{86}Sr$ ratio in co-existing garnet and diopside confirm the purity of our separates. It seems highly unlikely that random contamination of diopside (Sr = 140–400 p.p.m.) and garnet (Sr = 0.2 p.p.m.) with secondary mica flakes would result in identical $^{87}Sr/^{86}Sr$ ratios. Contamination would tend to dramatically increase the Rb/Sr and $^{87}Sr/^{86}Sr$ ratio of the garnet and diopside.

The most interesting aspect of the Sr and Nd data for the diopsides is the linear anticorrelation of $^{143}Nd/^{144}Nd$ with $^{87}Sr/^{86}Sr$ (Fig. 1). The data extend the 'mantle array', that was originally observed in uncontaminated oceanic and continental basalts[13,14], to $^{87}Sr/^{86}Sr$ values of 0.7075. Clearly mantle-derived liquids can have high $^{87}Sr/^{86}Sr$ ratios[15] and low $^{143}Nd/^{144}Nd$ ratios. All of the diopsides represent mantle regions that have a time-integrated light REE enrichment (Sm/Nd ratio < the bulk earth value). Other available data on garnet lherzolite nodules[13,16,17] reveal a Nd- and Sr-isotopic composition coincident with that of oceanic basalts. These lherzolites represent mantle with a time-integrated light REE depletion (Sm/Nd ratio > the bulk earth value). Clearly kimberlite nodules represent random samples of an inhomogeneous mantle characterised by both a LREE enrichment and depletion. Similarly data from alkali basalt nodules (ref. 18 and M.A.M. unpublished data) indicate that spinel lherzolite nodules represent mantle regions with both a time integrated light REE depletion and enrichment. These data have been summarised in Fig. 2 and compared with available basalt data.

Preliminary analyses of micas from garnet lherzolite nodules, plot off the mantle array as defined by the diopside data. Petrographic studies[8] indicate a secondary origin for these micas, that may involve the host kimberlite. However, Nd isotopic studies[17] of several fresh kimberlites indicate a source in the mantle with a chondritic REE abundance. This contrasts markedly with the two kimberlites analysed by DePaolo[19]. One highly serpentinised sample has a depleted source region while a slightly serpentinised sample is derived from an enriched source region. As these kimberlites are variably serpentinised their Nd and Sr isotopic compositions may reflect secondary processes. At this stage the mica data are difficult to interpret but we can say that a simple connection with the kimberlite magma is not indicated.

Sub-continental mantle

Ultramafic nodules found as spinel and garnet lherzolites in alkali basalts and kimberlites provide information on the isotopic and chemical constitution of the continental mantle. Mantle depletion and enrichment events will be recorded in these nodules throughout geological time. Rb–Sr[9,20] and Sm–Nd[16,21] measurements of minerals in some alkali basalt and kimberlite nodules record ages up to 3,000 Myr indicating that certain regions of the mantle have remained isolated for long periods of time. These ages may record ancient depletion events associated with continent formation, while Rb–Sr[22] and Sm–Nd (M.A.M., unpublished data) studies of metasomatised nodules may record recent enrichment events (for example, ≈200 Myr) associated with alkaline magmatism. The consistent and wide variation in the Sr isotopic ratio of diopsides in mantle nodules is believed to reflect this gross mantle heterogeneity[15,23]. The Sr and Nd data presented here support this contention and demonstrate that the sub-continental mantle contains regions with both time-integrated light REE enrichment and depletion (Figs 1 and 2).

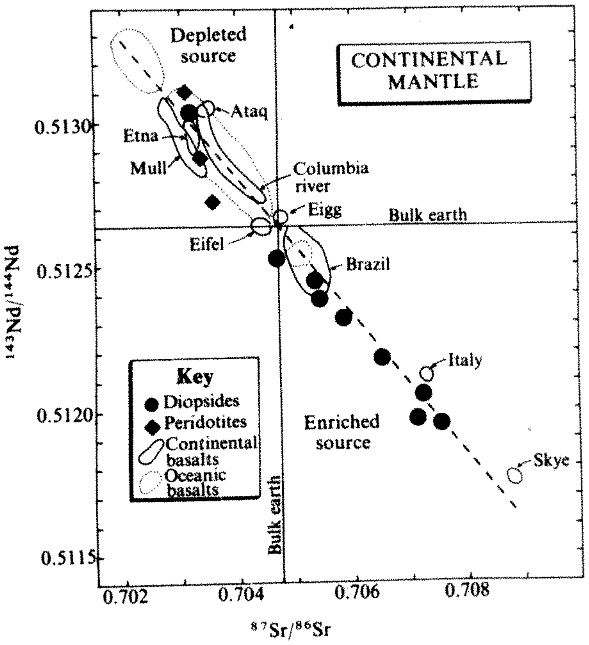

Fig. 1 ^{143}Nd/^{144}Nd and ^{87}Sr/^{86}Sr variation in diopsides from six kimberlite nodules (●) and one alkali basalt nodule from Nunivak, Alaska[24]. Comparative sources: Ataq[24], Mt Etna and Roccamonfina[4]; Mull, Eigg and Skye[5]; Eifel[27]; Columbia River[25]; and Brazilian flood basalts.[19]. Whole rock kimberlite nodule data[13] (◆) are shown for comparison.

Continental basalts are obviously derived from the sub-continental mantle and would be expected to reflect the gross heterogeneity described above. Figure 1 summarises available Nd and Sr isotopic data on continental basalts that are believed to represent uncontaminated mantle derived liquids. Basalts from Ataq, South Yemen[24]; Mt Etna, Italy[4]; Columbia River, US[25]; Rio Grande Rift[26] and other localities originated in depleted mantle regions similar to the source of oceanic basalts (Sm/Nd > the bulk earth value). However, continental flood basalts from Brazil[19] and rift valley basalts from Eifel, Germany[27] are derived from enriched (Sm/Nd < the bulk earth value) and chondritic (Sm/Nd ≈ the bulk earth value) source regions respectively. Nd and Sr data for uncontaminated basalts exhibit a considerable range in Nd and Sr isotopic composition that overlaps with that observed in diopsides from mantle nodules (Fig. 2). These data are therefore compatible with a grossly heterogeneous sub-continental mantle containing both depleted residual and enriched portions.

To our knowledge, very few suites of 'uncontaminated' basalts have been reported with low ^{143}Nd/^{144}Nd and high ^{87}Sr/^{86}Sr ratios. In most cases contamination with a crustal component has produced marked deviations[13,14] from the 'mantle array'. If we use the mantle array as a baseline against which contaminated suites can be compared, we may be able to define the approximate Nd and Sr isotopic composition of the 'mantle-derived liquid' that was subsequently contaminated during ascent through the continental crust. In the case of the Roccamonfina volcanic rocks from southern Italy[28] one sample (Fig. 1) has a Nd and Sr isotopic composition coincident with the mantle array as defined by the diopside data. Possibly this basalt represents a relatively uncontaminated volcanic rock derived from an enriched mantle. The associated volcanic rocks that plot to the right of the array represent mantle derived liquids variably contaminated with a crustal component[29], or uncontaminated liquids derived from metasomatised mantle[28]. One can also speculate that the Nd and Sr isotopic composition of an epigranite from Skye, Scotland[5,30] may approach that of the original mantle derived liquid. However, the chemically evolved nature of this rock indicates that it is a highly fractionated derivative of the original basalts. A closer look at the Skye volcanic rocks reveals two contaminated suites located in the upper left and lower right portions of Fig. 1. Carter *et al.*[30] suggest that the Skye volcanic rocks tapped a depleted mantle source but we suggest that perhaps the source was heterogeneous (that is, enriched and depleted).

Uncontaminated continental basalts, therefore, reflect dual mantle sources with both a time-integrated light REE depletion (Sm/Nd > the bulk earth value) and light REE enrichment (Sm/Nd < the bulk earth value). Similarly, careful investigation of contaminated suites of basalts in continental regions may provide evidence of enriched and depleted mantle regions. Basalt and nodule data are compatible with a grossly heterogeneous sub-continental mantle.

Table 1 ^{87}Sr/^{86}Sr and ^{143}Nd/^{144}Nd isotopic analyses of diopsides from micaceous garnet lherzolites found in kimberlite pipes

Locality	Rb/Sr	^{87}Sr/^{86}Sr	^{143}Nd/^{144}Nd*
Bultfontein B10 diopside	0.006	0.70646 ± 10	0.51216 ± 3

* Normalised to ^{146}Nd/^{144}Nd = 0.7219.

† Corrected for radiogenic Sr growth for ~75 Myr, the approximate pipe emplacement age. $87_{\lambda} = 1.42\times10^{-11}$ yr^{-1}.

The compatibility of uncontaminated basalt data with mantle peridotite isotopic data indicates that perhaps these garnet and spinel lherzolites are typical of the source rocks of LIL enriched continental volcanic rocks. Trace element analyses of these peridotites, however, reveal an insufficient quota of LIL elements necessary for the production of basaltic and alkaline magmas[6,7,31] It is generally agreed that the source is an aluminous peridotite and, that the majority of garnet and spinel lherzolites have a trace element content that can, after addition of a LIL element enriched fluid, produce alkaline magmas. We have shown elsewhere[12] that ≈5% metasomatism increases the trace element content of the source such that alkaline magmas

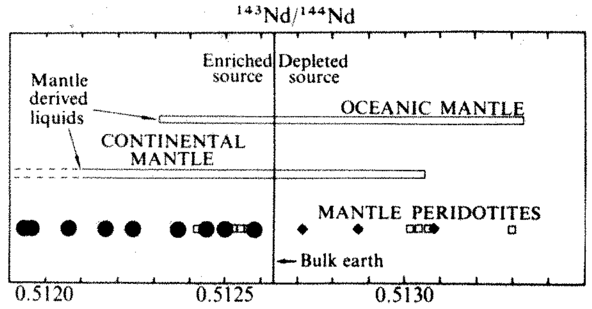

Fig. 2 $^{143}Nd/^{144}Nd$ variation in oceanic and continental basalts in relation to the mantle heterogeneity observed in diopsides from kimberlite (●) and alkali basalt nodules (refs 18, 24 and M.A.M., unpublished data) (□). Whole rock kimberlite nodule[13] data (◆) are included for comparison.

can be extracted by 5–20% melting. Other authors[32–34] have suggested that infiltration of metasomatic fluids provide the requisite amount of LIL elements and volatile fluxes that trigger anatexis. Therefore mantle peridotites containing accessory phases (amphibole, apatite, mica, sphene, and so on) are considered to be potential source materials. The diopsides analysed in this study are separated from multiply metasomatised garnet lherzolites containing both primary and secondary micas[8]. The metasomatised nature of the nodules is compatible with the isotopic data as metasomatism tends to lower the Sm/Nd ratio of the source region. Therefore phases with low Sm/Nd ratios would tend to record this enrichment event. (For comparison depletion events tend to increase the Sm/Nd ratio of the residual peridotite.)

In general there is clear evidence of recent or subrecent LIL and light REE enrichment of a metasomatic nature in the mantle source regions of oceanic and continental basalts (Fig. 1), but in the Nd and Sr isotopic data presented here we see the effects of ancient enrichment events in the sub-continental mantle. These metasomatic events are believed to be genetically related to upwelling of mantle plumes or blobs. Isotopic evidence for recent enrichment events is found in continental and ocean island basalts (Figs 1 and 2) that have $^{87}Sr/^{86}Sr$ lower than and $^{143}Nd/^{144}Nd$ ratios greater than, the bulk earth value. This indicates derivation from source regions with a time-integrated light REE depletion (Sm/Nd greater than the bulk earth value). A depleted source contrasts markedly with the LIL enriched nature of the basalts and can best be explained by a recent enrichment event in the source region. This event presumably occurred so close to the time of eruption that it has not, as yet, been recorded in the $^{143}Nd/^{144}Nd$ ratio. Such recent events may have also affected the source regions of continental basalts from Nunivak island, Alaska, the Ataq diatreme, South Yemen[12], and the Eifel rift valley, Germany (Fig. 1). We have demonstrated elsewhere[12,24] that in the case of Ataq recent enrichment or metasomatism is a precursor to continental alkaline magmatism. Rb–Sr data on basalts from the vicinity of Ataq may indicate that the event occurred 30–40 Myr before eruption of the basalts. Similarly Erlank and Shimizu[20] reported an age of 148 ± 7 Myr for a metasomatic event in kimberlite nodules, that may represent a precursor to Karroo volcanism. Recent enrichment (231 ± 25 Myr) is also evident in metasomatically veined lherzolite nodules from Dish Hill, California (M.A.M., unpublished data). One can infer from this that enrichment events, or metasomatic precursors to alkaline (or tholeiitic) magmatism represent recent mantle events ($\leq$250 Myr) superimposed on ancient, depleted, sub-continental mantle.

Enriched source regions resulting from such mantle enrichment (and associated diapirism) may temporarily be stored in the sub-continental mantle and adhere to the base of the continental (or oceanic) lithosphere[3]. Isotopic ageing will result producing the gross heterogeneities evident in the sub-continental lithosphere. However, note that these heterogeneities may result from original regional heterogeneities in the mesosphere[3] if the plumes are derived from the mesosphere, or from mixing of mesospheric (lower mantle) and upper mantle components[37]. Stored plumes may eventually be reactivated giving rise to basalts with radiogenically enriched $^{87}Sr/^{86}Sr$ ratios and $^{143}Nd/^{144}Nd$ ratios that reveal a time-integrated light REE enrichment in the source region (Sm/Nd < the bulk earth value). Such enriched sources, that are ancient in age, are found primarily below continents (Fig. 1) and are volumetrically insignificant in the oceanic mantle. For example, we find trivial amounts of undifferentiated mantle as plumes below only two oceanic islands (see refs 35, 36), whereas melting of ancient enriched mantle is more common in the source regions of continental flood basalts and other continental volcanic rocks (Fig. 1). Furthermore the relative predominance of enriched mantle in sub-continental regions complements the depleted nature of the oceanic mantle. Such a balance must exist somewhere if the assumption of a planetary distribution for the bulk earth is correct.

Conclusions

Hence, diopsides separated from kimberlite peridotite nodules exhibit a considerable range in Sr and Nd isotopes extending the mantle array to radiogenic $^{87}Sr/^{86}Sr$ values. It is evident from consideration of these data, and unpublished data on alkali basalt nodules, that the sub-continental mantle has been subjected to various enrichment events that produce a grossly heterogeneous mantle. The bulk of the sub-continental mantle may be depleted (as shown by the increase in Sm/Nd ratio) during continental formation, resulting in very old ages in most anhydrous residual nodules. However, the gross heterogeneity may result from the superposition of recent ($\leq$200 Myr) and in some cases ancient enrichment events (for example, a decrease in Sm/Nd ratio) on the already depleted mantle. Regions of the mantle sampled by alkali basalts and kimberlites will therefore be characterised by both a time-integrated light REE depletion and light REE enrichment.

The analytical work was done in the isotope laboratory of the Department of Geology and Geophysics and was supported by NSF grant EAR 7-75-14806. We thank Tony Carswell and Ian MacGregor for samples, and S. Moorbath and S. Hart for helpful comments.

γ-β-Thalassaemia studies showing that deletion of the γ- and δ-genes influences β-globin gene expression in man

In γ-β-thalassaemia, human γ- and β-globin gene expression is suppressed; this results in a severe anaemia in newborns which subsequently develops into a β-thalassaemia syndrome in adult life. This hereditary disease is now shown to be the result of a deletion of at least 40,000 base pairs of the $\gamma\delta\beta$-globin gene locus. The γ- and δ-globin genes are deleted in the affected chromosome but, surprisingly, the β-globin gene is still present, together with a large segment of the DNA sequences flanking the gene on its 5'-side and the entire region on the 3'-side of the gene. Hence, a deletion of DNA far from the β-globin gene results in the suppression of its activity.

THE human non-α-globin genes are clustered in a short region of chromosome 11. During fetal life, the major haemoglobin expressed is HbF ($\alpha_2\gamma_2$) where the γ-chains are coded for by two non-allelic γ-globin genes (Gγ and Aγ). At about the time of birth, the expression of the γ-globin genes gradually ceases and HbF is replaced by HbA ($\alpha_2\beta_2$) and a low level of HbA$_2$ ($\alpha_2\delta_2$) (ref. 1). The fetal and adult genes are closely linked and gene mapping studies using Southern blotting[2] and the analysis of cloned genes have established the physical linkage of the δ- and β-genes[3,4], the two γ-genes[5] and the tie up between these maps to describe the linkage between these four genes[6–8]. Figure 1 shows the physical map of the β-related globin genes.

Several well-defined defects in the functioning of these genes have been described. In addition to the abnormal haemoglobin proteins (such as HbS in sickle cell anaemia), inherited diseases collectively called the thalassaemias have been described in which the level of expression of these genes is altered. In the most common type, β-thalassaemia, two forms of the disease can be distinguished. In β^+-thalassaemia, reduced amounts of β-globin are produced as a result of low levels of globin messenger RNA (mRNA)[1]. In the second type, β^0-thalassaemia, no β-globin is produced. β^0-Thalassaemia is a heterogeneous disease and except for two forms of this disease[9–11] the molecular basis is unknown. The rarer disease, $\delta\beta^0$-thalassaemia, is the result of a gene deletion (see ref. 1 for references) which inactivates both the δ- and β-globin genes. The deletion maps from the intervening sequence of the δ-globin gene[6,12,13] to a site 1,800 base pairs past the β-globin gene[13]; altogether, 10,000 base pairs have been deleted[13]. Finally, in the condition HPFH (hereditary persistence of fetal haemoglobin) the entire $\delta\beta$-globin gene region has been deleted (see ref. 1 for older references), spanning from sites 4 kilobase pairs in front of the δ-globin gene in two cases[6,7] and 7 kilobase pairs in front of the δ-globin gene in another (R. Bernards and R.A.F., unpublished) to a position well past the β-globin gene.

Several other rare forms of thalassaemia affecting the β-related globin genes are known. In γ-β-thalassaemia, first described by Kan *et al.*[14], a severe anaemia is evident in newborns as a result of a reduction of the γ/α synthetic ratio to about 0.5. As γ-chain synthesis is switched off in the course of normal development, the disease develops into a mild β-thalassaemia which is unusual in that the HbA$_2$ ($\alpha_2\delta_2$) levels are normal, rather than elevated as in classical β-thalassaemia. To explain this, Kan *et al.*[14] postulated that the entire $\gamma\delta\beta$-region has been deleted in γ-β-thalassaemia.

We show here that the Gγ-, Aγ- and δ-globin genes have been deleted in γ-β-thalassaemia. Surprisingly, however, the β-globin gene is present, together with 2,500 base pairs on its immediate 5'-side and the entire 3'-extragenic region. Figure 1 compares the structure of the affected region in γ-β-thalassaemia with the corresponding region of normal DNA.

γ-β-Thalassaemia in a Dutch family

One of us (M.O.) has been involved in the treatment of a Dutch family which exhibits the same clinical symptoms as those originally described for γ-β-thalassaemia[14]. These data (including an extensive family study) will be presented in detail else-

Table 1 Haematological data and β/α specific activity ratios for γ-β-thalassaemia

	Patient 2	Normal females
Hb (g dl^{-1})	9.7	12.0–15.0
Erythrocytes ($\times 10^{12}$ l$^{\times 1}$)	4.5	3.5–5.5
Mean cell volume of erythrocytes (fl)	67	82–94
Reticulocyte count (%)	5.2	0.5–1
HbA$_2$ (% of total Hb)	3.1	1.9–3.0
HbF (% of total Hb)	1.0	0.1–1.5
β/α synthetic chain ratio	0.49	0.9–1.0

Haemoglobin was determined by the cyanomethaemoglobin method, the erythrocytes counted in a Hycell counter and the mean cell volume of erythrocytes calculated from the erythrocyte count and the haematocrit. The reticulocyte count was determined by microscopy and the HbA$_2$ and HbF determined as described in refs 20 and 21. The β/α synthetic ratios were determined by the incorporation of ^{3}H-leucine by reticulocytes followed by the separation of the globin chains according to ref. 22. The specific activity of each chain was determined by hydrolysing the α- and β-globins and determining the leucine content directly. The values for normal females are the average values found in the laboratories of D.R. and L.B.

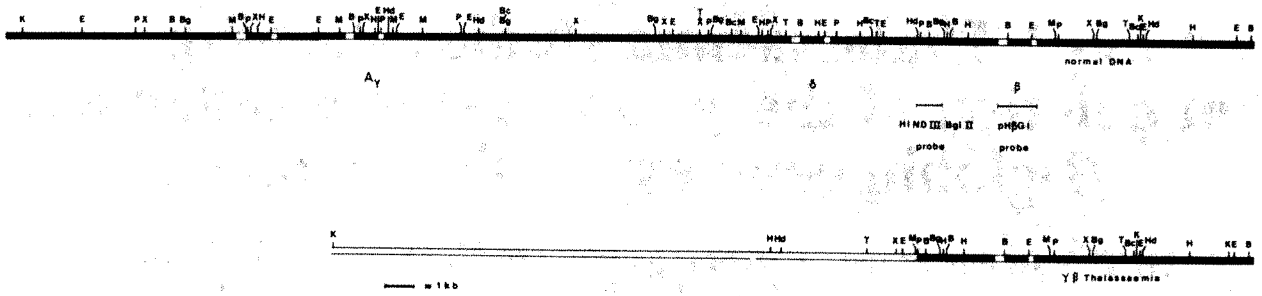

Fig. 1 Restriction map of the γ-β-thalassaemic globin genes compared with normal DNA. The probable positions of the coding regions are shown as open boxes. It should be stressed that only extragenic sites which can be detected for a given enzyme by the blotting analysis are those closest to the sequence complementary to the probe used. Certain sites between the δ- and β-globin genes are as originally described in ref. 6. The positions of the remaining sites are described in refs 8 and 13, and most were originally described in refs 3 and 5. The *Msp*I sites are from L.H.T.V.P. and R.A.F. (unpublished). The *Kpn*I site to the 5'-side of the Gγ-globin gene has been remapped at 7.5 kilobases upstream from the gene in *Hpa*I + *Kpn*I double digests. This means that the *Kpn*I fragment is 39 and not 46 kilobases, as estimated from its electrophoretic mobility in agarose gels[8]. B, *Bam*HI; Bc, *Bcl*I; Bg, *Bgl*II; E, *Eco*RI; H, *Hpa*I; Hd, *Hin*dIII; K, *Kpn*I; M, *Msp*I; P, *Pst*I; T, *Taq*YI; X, *Xba*I.

where. Briefly, of a family with 13 progeny, 7 (now adults) were found to exhibit a β-thalassaemia minor with normal HbA_2 levels rather than the elevated HbA_2 characteristic of classical β-thalassaemia. Two of these adults have been analysed in the present article (patients 2 and 3). Some of the relevant haematological data for patient 2 are compared with the average data for normal individuals in Table 1. In particular, note that the β/α chain synthetic ratio was 0.49 in this case, rather than the 0.9–1.1 values found for normal individuals.

In the past 14 yr, nine infants, progeny of the seven affected individuals described above, have been examined by M.O. They showed the clinical course described by Kan *et al.*[14] with severe postnatal haemolytic anaemia, a mixed hyperbilirubinaemia with both direct and indirect bilirubin being elevated; a drastic decrease in haemoglobin level occurred in the immediate postnatal period.

During postnatal development, a chronic microcytic anaemia persisted in all cases, with normal or near normal reticulocyte counts and bilirubin levels. The globin synthetic ratios have been measured in two affected infants, namely, a 4-month-old child of patient 2 and a newborn child of patient 3. In the first case the child showed 23% HbF, with a β/α ratio of 0.56 and a γ/α ratio of 0.74. In the second case 87% HbF was found, with a γ/α synthetic ratio of 0.5. Thus, γ- and β-gene expression is impaired in the same way as originally described by Kan *et al.*[14]. As the γ-lesion has only been observed in several children of the sibling adults with the β-thalassaemia trait (whose spouses were in all cases haematologically normal), there can be no doubt that the γ-β-thalassaemia lesion is carried on the same chromosome. (Normal infants have also been born in these families with neither γ- nor β-globin gene expression affected.)

Abnormal β-globin gene fragments in γ-β-thalassaemia

To analyse the globin gene structure in this disease, we isolated DNA from peripheral blood from two affected adult γ-β-thalassaemia heterozygotes (patients 2 and 3) and their normal spouses (1 and 4), digested the DNA with various restriction endonucleases and analysed the globin gene fragments by Southern blotting[2], followed by filter hybridisation[2,15,16] as described previously[3,4] using cloned human β and γ-complementary DNA (cDNA)[17] as probes for the β-δ- and γ-globin genes, respectively (see Fig. 2 legend for details).

Hybridisation of *Bgl*II, *Xba*I and *Bam*HI-digested DNA from the γ-β-thalassaemia patients with γ-gene probes (pHγG1)[17] showed only the normal γ-globin bands described previously[5] (Fig. 2). This must mean either that the γ-globin gene region is normal in γ-β-thalassaemia or that the entire γ-region has been deleted in the affected chromosome. The reduced intensity of the bands in the patients compared with the controls suggested the latter. Using probes for the β-globin structural gene sequences (pHβG1 DNA)[17], abnormal bands were seen in *Hin*dIII, *Eco*RI, *Xba*I, *Msp*I and *Taq*Y-digested DNA in addition to the normal bands derived from the unaffected chromosome (Fig. 2; Table 2). In contrast, the *Pst*I, *Bgl*II (Fig. 2) and *Hpa*I (Fig. 3) patterns for the δ- and β-globin genes of the thalassaemics were the same as for control individuals (Fig. 2; Table 2 gives the relevant sizes of the fragments). The *Bam*HI patterns for the control individuals and one of the patients are also the same; they do, however, differ from all other human DNAs that we have examined in that they contain a 22-kilobase 3' *Bam*HI β-globin gene fragment instead of the usual 8.6-kilobase fragment. The second patient is heterozygous for this *Bam*HI polymorphism; this DNA contains both the 22-kilobase and 8.6-kilobase 3' β *Bam*HI fragments. This *Bam*HI polymorphism is, however, not directly relevant to the γ-β-thalassaemia lesion because it is also found in individuals unaffected by the disease.

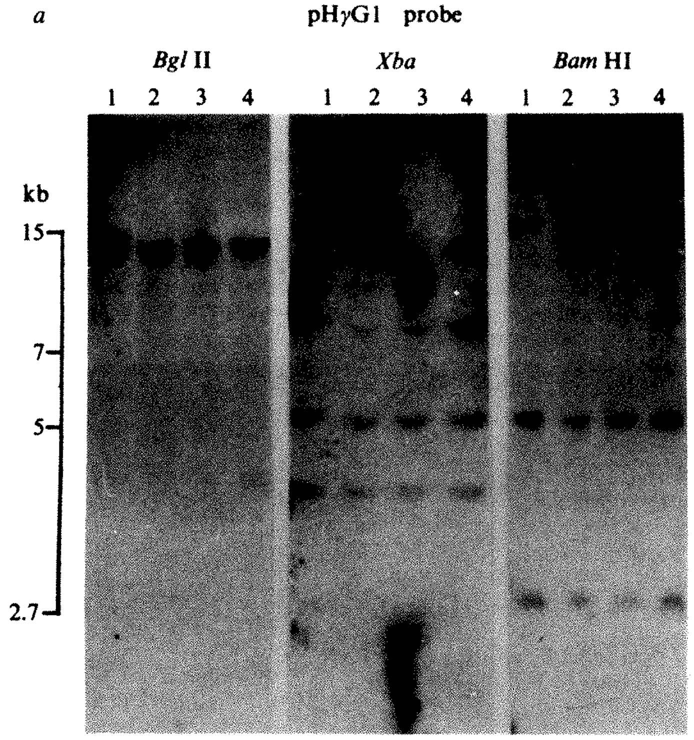
Inspection of the restriction map of the β-related globin gene locus (Fig. 1) suggests that a break has occurred in γ-β-thalassaemia in the 200-base pair region between *Hin*dIII and *Pst*I on the 5'-side of the β-globin gene: all cleavage sites on the 3'-side of this site are normal, whereas the *Hin*dIII, *Eco*RI, *Bcl*I, *Taq*YI, *Xba*I and *Msp*I sites on the 5'-side differ from the normal ones.

To confirm this, we hybridised the same DNA samples with the 0.9-kilobase *Hin*dIII + *Bgl*II fragment containing the DNA region 1.9–2.8 kilobases to the 5'-side of the β-globin gene, that is, the region of the putative break point. Figure 1 shows where this probe is located on the map. The *Bgl*II–*Hin*dIII probe detects all the abnormal 'β'-globin bands detected above and the corresponding normal β-globin fragments (Fig. 4). We have also mapped the 'abnormal' cleavage sites of those enzymes (*Bam*HI, *Hpa*I and *Pst*I) that gave apparently normal patterns with pHβGI probes, because the cleavage sites mapped with pHβGI are located between the β-globin gene and the break point in γ-β-thalassaemia. Thus, *Bam*HI gives a 0.7-kilobase band with both normal and γ-β-thalassaemia patient DNAs (Fig. 4); this 0.7-kilobase fragment is adjacent to the 1.8-kilobase *Bam*HI β-fragment at its 5'-terminus[6]. The break point must, therefore, be to the 5'-side of this (or alternatively, it is within this fragment but the new *Bam*HI site is coincidentally at the same relative position as the 'old' site). In DNA cut with *Hpa*I, a novel fragment of 5.6 kilobases is seen (in contrast to Fig. 3). DNA cut with *Pst*I still does not show any abnormal bands; only the 4.4-kilobase β-globin gene fragment is visible. We presume that we do not detect an abnormal *Pst*I fragment because the break point is essentially at the normal *Pst*I site; in this case, little or no homology would be seen between the fragment spanning the break point and our *Bgl*II-*Hin*dIII probe.

Mapping the size of the deletion in γ-β-thalassaemia

To confirm that the break point we have deduced above is indeed the correct explanation for the γ-β-thalassaemia fragment pattern, we have mapped several cleavage sites around the β-globin gene in double digests. The abnormal 5′ *Eco*RI and *Msp*I sites have been mapped in *Pst*I + *Eco*RI and *Msp*I + *Eco*RI double digests; Table 2 shows that the data from these digests fit with the position of the break point already deduced.

All the data support a model in which a break in the chromosome has occurred between *Pst*I and *Hin*dIII 2.5 kilobases upstream from the β-globin gene. To determine whether a deletion or inversion has occurred, we analysed *Kpn*I digests. In normal DNA, *Kpn*I yields a single 39-kilobase globin gene fragment containing the Gγ-, Aγ-, δ- and β-globin genes (Fig. 1, ref. 8). In DNA from the γ-β-thalassaemia patients, a second 27-kilobase band is visible which hybridises with β-globin probes but not γ-globin probes (Fig. 5). Apparently, a large deletion has occurred in γ-β-thalassaemia, eliminating the γ-globin genes entirely. The 3′ *Kpn*I site was mapped in γ-β-thalassaemia DNA in *Kpn*I + *Hpa*I and *Kpn*I + *Bam*HI double digests. To our surprise, two 3′ *Kpn*I sites are indicated in this experiment in both the patients and their normal spouses, who are also from this region of The Netherlands. The closest *Kpn*I site to the β-globin gene is 5.5 kilobases to the 3′-side of the 5′ β-globin *Hpa*I site and corresponds to the 3′ β-globin *Kpn*I site already mapped by us in several DNAs from normal Dutch, Indian and English individuals, an Italian $\text{Hb}_{\text{Lepore}}$ patient and an Italian $\delta\beta^0$-thalassaemia patient. The second site lies to the 3′-side of the *Hpa*I site downstream from the β-globin gene and,



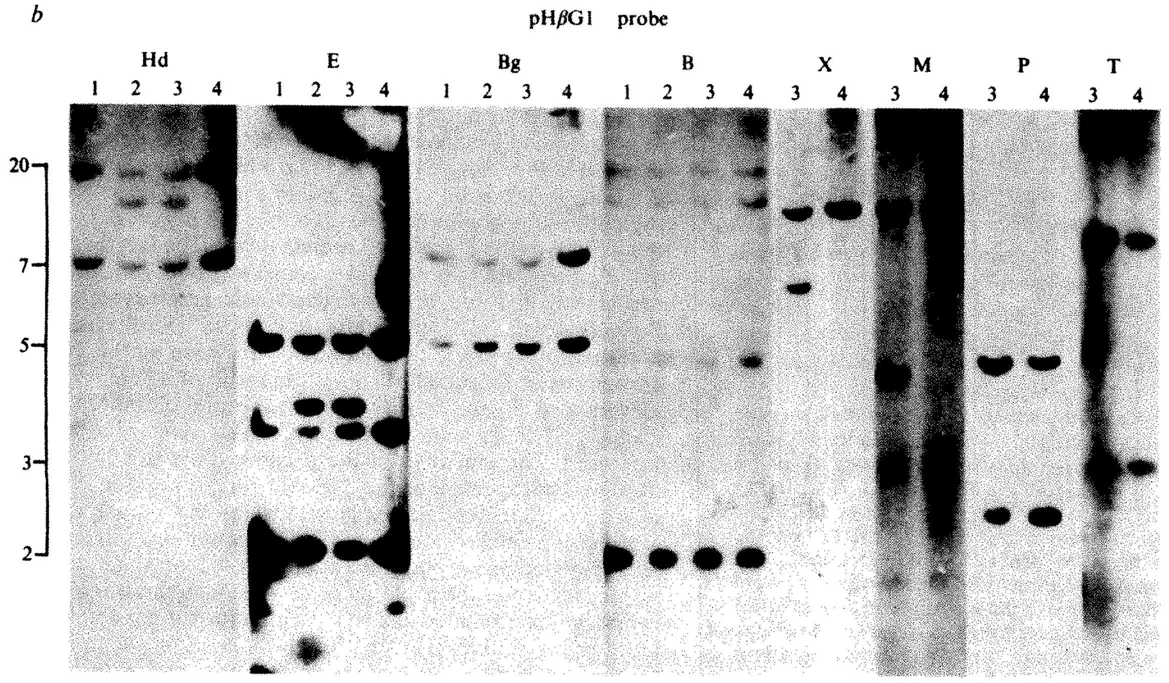


Fig. 2 γ-, δ- and β-globin gene fragments in γ-β-thalassaemia. DNA was isolated from peripheral blood of two γ-β-thalassaemic patients and their normal spouses as described[3] except that a 30-min incubation in proteinase K (100 $\mu\text{g ml}^{-1}$) in 1% SDS, 0.1 M EDTA and 0.15 M NaCl (*p*H 8.0) at 37 °C preceded the phenol extractions. DNA was digested with the relevant restriction endonucleases[3] and about 10 μg per lane was electrophoresed in 0.7% agarose gels for 36–48 h at 0.7 V cm^{-1}. The DNA was blotted[2] on to nitrocellulose filters and hybridised as previously described[3,16] except that 9% dextran sulphate (Sigma, 500,000 molecular weight) was added to the pre-hybridisation wash and to the hybridisation solution[23]. Hybridisation probes were pHβG1 (*a*) and pHγG1 (*b*) for the $\delta\beta$- and γ-genes, respectively[3,5,17]. After a 12-h hybridisation (using 1 ng of ^{32}P-labelled DNA probe per ml; 4×10^8 c.p.m. per μg) at 65 °C, the filters were washed as described elsewhere[3]. Bands were detected by autoradiography for 12–48 h as previously described[3]. For abbreviations, see Fig. 1 legend. The two additional faint bands seen in the *Bam*HI–pHγG1 hybridisation are partial digestion products.

therefore, only half the 7.7-kilobase *Hpa*I band is cut (Fig. 3). The second polymorphic *Kpn*I site is precisely located in the *Bam*HI + *Kpn*I double digest; a new 7.7-kilobase *Bam*HI + *Kpn*I double digest fragment places this site at 7.7 kilobases from the intragenic β-globin *Bam*HI site, 3.1 kilobases past the 'normal' *Kpn*I site (Fig. 3). Patient 3 and control 4 are, therefore, heterozygous for a 3′ *Kpn*I polymorphism as well as being homozygous for the 3′ *Bam*HI polymorphism described above.

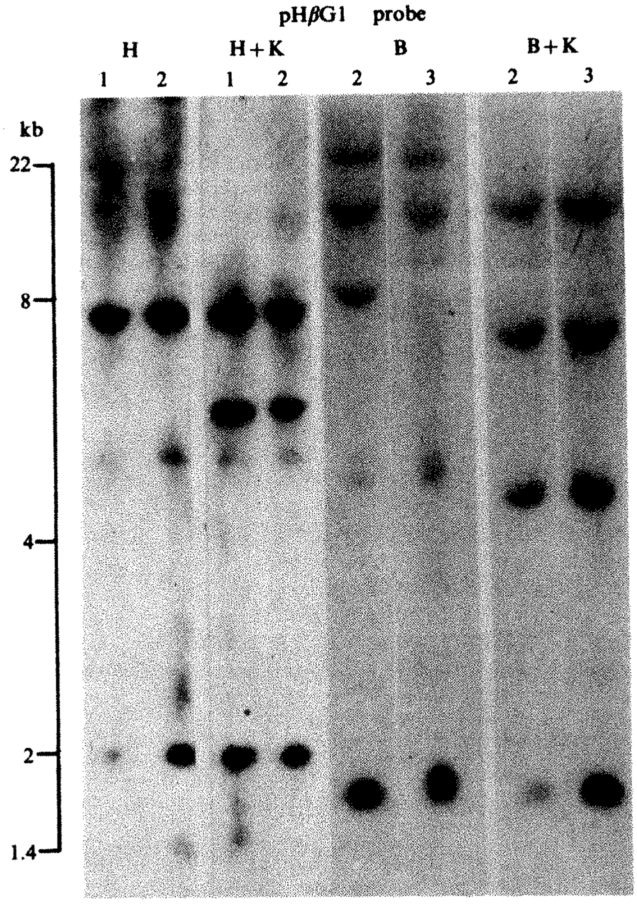

Fig. 3 Mapping the *Kpn*I sites at the 3′-side of the β-globin gene in DNA from normal individuals and γ-β-thalassaemics: a 3′ *Kpn*I polymorphism. DNA from γ-β-thalassaemics (patient 3) or his normal spouse (no. 4) was digested with *Kpn*I (K), *Hpa*I (H) or *Bam*HI (B) either single or in double digests. Only one-half of the 7.7-kilobase *Hpa*I β-fragment is cleaved by *Kpn*I to give the *Hpa*I + *Kpn*I double digest fragment of 5.5 kilobases; one half of the 22-kilobase 3′ *Bam*HI β-fragment is cleaved at the same *Kpn*I site described previously[8] to give the 4.6-kilobase double digest fragment and the other half lacks this site and is cleaved at a second *Kpn*I site 3.1 kilobases further in the 3′ direction. For abbreviations, see Fig. 1 legend.

Table 2 Size of globin gene fragments in restriction enzyme digests

	Fragment size		
Enzyme	γ-β-Thalassaemia gene	δ-Gene	β-Gene
Detected with pHβG1 probe			
*Hind*III	12.0	17.0	7.6
*Eco*RI	4.2	2.3 + 1.9	5.8 + 3.7
*Bgl*II	NAB	8.4	5.0
*Bam*HI	NAB	15.0 + 4.3	1.8 + 22 or 8.6
*Xba*I	6.4	10.8	
*Msp*I	4.5	10.5	
*Pst*I	NAB	2.3	4.4
*Taq*YI	9.0	8.6	3.1
*Pst*I + *Eco*RI	NAB	1.7 + 0.6	3.6 + 0.8
*Hpa*I	NAB	1.9 + 1.4	7.8
*Eco*RI + *Msp*I	3.7	2.3 + 1.9	5.8 + 0.8
*Kpn*I	27	39	
*Kpn*I + *Hpa*I	NAB	1.9 + 1.4	7.8 or 5.5
*Bam*HI + *Knp*I	NAB	15.0 + 4.3	7.7 or 4.6
Detected with *Hind*III–*Bgl*II probe			
*Hind*III	12.0	—	7.6
*Eco*RI	4.2	—	5.8
*Bam*HI	NAB	4.3	0.7
*Xba*I	6.4	10.8	
*Hpa*I	5.8	—	3.1
*Kpn*I + *Hpa*I	5.8	—	3.1

The γ-β-thalassaemia fragments are from the present paper. The β- and δ-globin gene fragments have been reported previously[3,6,8,13]. NAB, no additional bands.

Figure 1 compares the maps of the normal globin gene region with that of γ-β-thalassaemics. How large is the deletion in γ-β-thalassaemia? The minimal size of the deletion seems superficially to be 12 kilobases, that is, the difference in size between the normal *Kpn*I fragment (39 kilobases) and the abnormal fragment (27 kilobases). Inspection of the map in Fig. 1 shows, however, that this cannot be the case. This would place the 5′-break point in the γ-globin gene region and would result in abnormal *Bam*HI, *Xba*I and *Bgl*II γ-globin gene fragments; these are not seen. The explanation must, therefore, be that the deletion extends past the *Kpn*I site on the 5′-side of the γ-globin genes; the entire γ-globin gene region is deleted in γ-β-thalassaemia. *Hpa*I digests of DNA from γ-β-thalassaemics define the minimal size of the deletion. Because the γ-globin genes are completely deleted in γ-β-thalassaemia, the first *Hpa*I site present on the 5′-side of the break point of the deletion must be past both γ-globin genes. Fritsch *et al.*[6] have shown that the first *Hpa*I site to the 5′-side of the Gγ-globin gene is 23 kilobases upstream from the gene in normal DNA and we have confirmed this in several normal individuals. Let us assume that this is the 5′ *Hpa*I site of the abnormal 5.6-kilobase *Hpa*I fragment in γ-β-thalassaemia. At its 3′-end the 5.6-kilobase fragment must contain the 0.9 kilobases of DNA which extend from the 3′-break point of the deletion to the *Hpa*I site in front of the β-globin gene. The closest position for the 5′-break point of the deletion is, therefore, 4.7 kilobases (5.6–0.9) from the '5′ Gγ' *Hpa*I site; inspection of Fig. 1 shows that this predicts a minimal deletion of 42 kilobases. Maniatis and his colleagues have recently shown that an embryonic globin gene is located to the 5′-side of the Gγ-globin gene; as this ε-gene is 8 kilobases upstream from the Gγ-globin gene (T. Maniatis, personal communication) we conclude that this gene is deleted in γ-β-thalassaemia.

Discussion

Comparison of the detailed maps of restriction endonuclease cleavage sites in normal DNA[3–8] and DNA from γ-β-thalassaemic patients has shown that this disease is the result of a large deletion in the γδβ-globin gene locus which has its 3′-end point 2.5 kilobases in front of the β-globin gene. The Gγ-, Aγ- and δ-globin genes are entirely deleted, but the β-globin gene and the regions to the 3′-side of β remain intact. The fact that the γ- and δ-globin genes are deleted explains why both gene products are grossly reduced in γ-β-thalassaemic heterozygotes. The δ-globin levels are apparently normal in γ-β-thalassaemia heterozygotes despite the deletion of this gene on the affected chromosome. Presumably, this is the result of a compensatory elevation of δ-gene activity from the second chromosome; in classical β-thalassaemia, δ-globin levels are also usually increased. The inactivity of the β-globin gene in adult life is, however, unexpected, as the β-globin gene is present.

We see four possible explanations for this paradox. First, γ-β-thalassaemia results from a double mutation, a deletion of the γδ-region and a point mutation or a second small deletion which inactivates the β-globin gene. Although this is unlikely it cannot yet be excluded and so remains a formal possibility. It is more probable, however, that the β-thalassaemia seen in γ-β-thalassaemics is the result of the deletion mapped in this article.

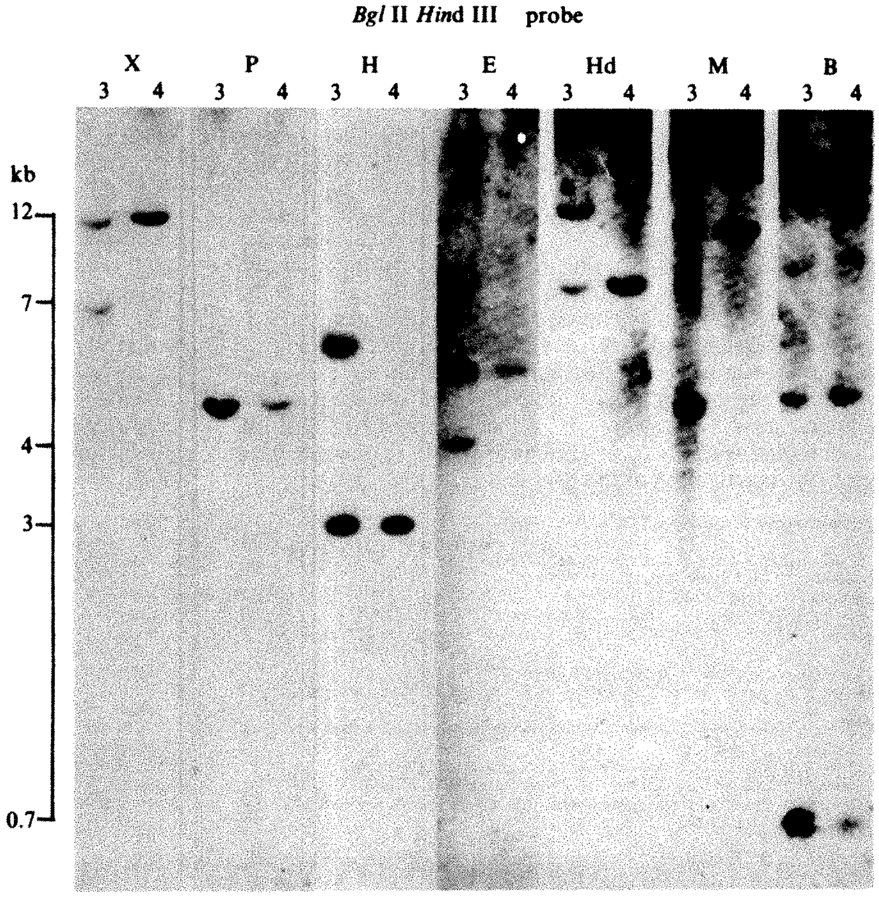

Fig. 4 β-globin gene fragments in γ-β-thalassaemia, detected with the *Bgl*II-*Hind*III probe for the 5′-extragenic regions of the β-globin gene. Filter-bound DNA from a γ-β-thalassaemic patient and his normal spouse was prepared as described in Fig. 2 legend. The *Bgl*II-*Hind*III probe was prepared from a cloned *Hind*III fragment from the β-globin gene of a β^0-thalassaemia patient (F. G. Grosveld, H. H. Dahl, E. De Boer and R.A.F., unpublished) by double digestion with these enzymes, followed by electrophoresis on a 1.2% agarose gel. The fragments were extracted according to the method of Tabak and Flavell[24] except that the DNA fragment was eluted from the hydroxyapatite with 400 µl of 0.5 M EDTA (*p*H 7.5) instead of phosphate buffer. For abbreviations, see Fig. 1 legend.

CALCUTTA

The effect might be either *cis*- or *trans*-acting.

Second, it is possible that the reduction in β-globin gene expression is a result of the deletion mapped, but that its effect is not confined to the 'deleted' chromosome; it could be a general effect on both β-globin genes. To explain this, we could postulate that a *trans*-acting component is coded for by a gene in the $\gamma\delta$-globin gene region. The fact that the β/α synthetic ratio is 0.49 instead of 1 is, however, more in line with the inactivation of one chromosome, presumably from the one carrying the deletion, by a *cis*-acting effect; a precise reduction of β-globin gene expression by a factor of two as a result of a drop in the level of a *trans*-acting component by the same factor seems unlikely, but this is not excluded by our data.

How do we explain the lack of β-globin gene activity by a *cis*-acting effect of the deletion? We could argue that the transcription unit of the β-globin gene extends into the DNA that has been deleted; conceivably the promoter or another regulatory sequence would be located more than 2.5 kilobases to the 5′-side of the β-globin gene. This is unlikely; a rabbit β-globin gene containing only 1.4 kilobases of the sequences upstream from the 5′-end of the gene is transcribed to give active globin mRNA when introduced into mouse L cells by transformation[18], there is no reason to believe that the homologous human gene would do otherwise. We have also mapped the unspliced rabbit β-globin pre-mRNA to be a transcript of the mRNA coding regions plus the two intervening sequences; the 5′-extragenic sequences are not present on this transcript[19].

The final explanation is that sequences far from the β-globin gene also influence its activity in *cis*. For example, a DNA sequence in the $\gamma\delta$-globin gene region could be essential for β-globin gene activity. Specifically, we have considered the possibility that the $\gamma\delta\beta$-region is split into chromosomal domains containing the fetal (Gγ and Aγ) and adult (δ and β) globin genes, respectively[12]. DNA sequences upstream from the δ-globin gene might be necessary to organise an active configuration for the whole $\delta\beta$-region; their deletion would render this impossible and hence inactivate the β-globin gene,

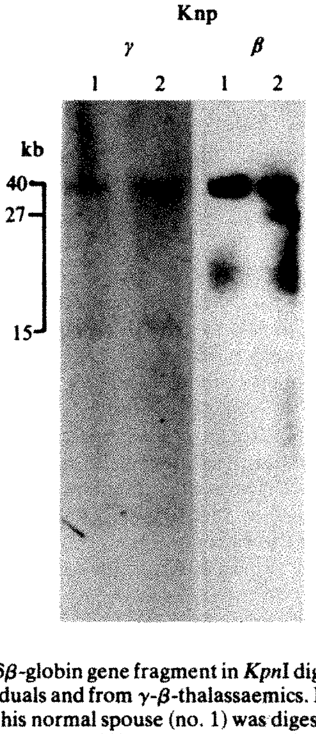

Fig. 5 the $\gamma\delta\beta$-globin gene fragment in *Kpn*I digests of DNA from normal individuals and from γ-β-thalassaemics. DNA, 10 µg, from patient 2 and his normal spouse (no. 1) was digested with *Kpn*I and electrophoresed on a 0.5% agarose gel for 72 h at 1 V cm^{-1}. The DNA was blotted, hybridised to either pHγGl or pHβGl DNA and further processed as described in Fig. 3 legend. The γ-probe filter was washed only to 0.3 × SSC to detect possible abnormal embryonic globin gene fragments. The faint 15-kilobase band contains the embryonic ε-genes and the 39-kilobase band contains the Gγ-, Aγ-, δ- and β-globin genes (see Fig. 1, ref. 8). Note that the 27-kilobase fragment in the DNA from the γ-β-thalassaemic patient only hybridises with the β-probe.

even though it would remain present on the chromosome. If these putative sequences were closely linked to the δ-globin gene and if they were essential for β-globin gene expression, the presence of the δ-globin gene in the population would be selected for by this linkage. This might explain why the apparently functionless δ-globin gene (which only contributes about 3% of the adult non-α-globin chains) is maintained in the human gene pool. It is also conceivable that some types of classical β-thalassaemia might be the result of mutations in the same DNA sequences discussed here, that is, further from the β-globin gene than has been hitherto considered.

Alternatively, the inactivation of the β-globin gene in γ-β-thalassaemia might be the result of a 'position effect' of the type previously described in *Drosophila*; here, the juxtaposition of a gene and a segment of heterochromatin results in the inactivation of the gene. Conceivably, the 5′-break point of the deletion in γ-β-thalassaemia is in a segment of heterochromatin which causes the inactivation of the β-globin gene when translocated to a position next to the gene.

The existence of sequences influencing gene expression in eukaryotes over large distances has its precedents. The mapping of distal DNA sequences in the human β- and δ-globin gene regions, which influence the expression of the γ-globin genes, has recently been described by ourselves[13] and by others[6,7]. In the latter cases, however, the putative regulatory sequences repress γ-globin gene expression in adult life; their deletion results in the persistence of γ-globin gene expression. In the case described here, the opposite is seen, namely, regulatory sequences are required to activate β-globin gene expression. Hopefully, the analysis of other rare types of thalassaemia may further identify DNA regions involved in the expression of the human fetal and adult globin genes.

Test of the inverse Compton model for Cygnus X-1

E. P. T. Liang

Institute of Theoretical Physics, Stanford University, Stanford,
California 94305

The X-ray spectrum of Cygnus X-1 from ~1 keV to ~200 keV exhibits two distinct components. The spectrum below ~10 keV is soft and may be the tail of comptonised black body if the turnover at ~1 keV is real, while that above ~10 keV is a simple power law[1,2]. The spectra above 200 keV remain uncertain with some showing a cutoff but others a continuation of the power law[3]. The power law hard spectrum is thought to be the result of unsaturated Compton up-scattering of soft photons by hot thermal electrons[4]. The comptonisation region may be the optically thin inner part of the disk or spherical accretion flow near the black hole or a hot corona surrounding a thin disk[1]. The unsaturated Compton model is attractive as it accounts for the power law spectrum with index $\alpha \sim 1$ ($I_\nu \propto \nu^{-\alpha}$) and the alleged high electron temperature ($T_e > 10^9$ K). However, there are still questions about the origin of the soft photon supply and stability. As important conclusions are drawn from this model (for example, interpretation of the high energy cutoff as a measure of the electron temperature and α as a measure of the Komponeet parameter $y \equiv (4kT_e/m_ec^2)\tau_{es}^2 \simeq 4/(3\alpha+\alpha^2)$, $\tau_{es} \equiv$ electron scattering depth)[4,5], it is crucial to have independent verification of this idea. We propose here a more critical test and show that the hard X-ray data available to date strongly support this model.

A steady supply of soft photons of mean energy $h\nu_0$ and luminosity L_i injected into a comptonising medium of Komponeet parameter y will emerge with luminosity $L \sim L_i\,e^y$ at least for $y \leqslant 1.5$ (unsaturated comptonisation, for saturated comptonisation $y \gg 1$ and $L \sim L_i 3kT_e/h\nu_0$; see refs 5, 6 for numerical results of intermediate regimes). L has two spectral components: a power law of total luminosity L_h for photons with many scatterings and a residual soft component of luminosity L_s for photons with few scatterings. Using photon number conservation one finds

$$L_s = L_i\left(1 - q\frac{h\nu_0}{kT_e}e^y\right)\left(1 - \frac{qh\nu_0}{kT_e}\right)^{-1};$$

$$L_h = L_i(e^y - 1)\left(1 - \frac{qh\nu_0}{kT_e}\right)^{-1}$$

where $q \sim 0(1)$ depends weakly on y and spectral details of L_i. Hence for $h\nu_0 \ll kT_e$, we have the important prediction

$$L_h/L_s = e^y - 1 \quad \text{for} \quad y \leqslant 1.5 \tag{1}$$

We now consider whether the large body of spectral data of Cyg X-1 reported in the past 15 yr is consistent with equation (1), assuming that we can identify L_s with the 2–10 keV luminosity and L_h with the 10–200 keV luminosity. Whether the 2–10 keV luminosity itself involves some comptonisation of even softer photons with electrons of lower T_e and y should not affect this test. It is assumed in the above identification that the (highly uncertain) luminosity below ~1 keV originates from a spatially separate region and is unrelated to that above 10 keV.

The sharpest test of equation (1) comes from the 'transition' data when Cyg X-1 exhibited anticorrelated variations in soft and hard X-ray luminosities, with the pivoting point at ~10 keV. We can find published simultaneous soft and hard X-ray data for only three such events (March 1971, May 1975, November 1975–February 1976), although there must be others (see ref. 8). As crude estimates we simply extrapolate published spectra from 2 to 10 keV for L_s and from 10 to 200 for L_h.

* P. Nolan, unpublished HEAO 1 data.

Table 1 lists the data for the transitions. Despite expected errors they show surprising agreement with theory except for the (soft) 'high' state before the 1971 transition, whose large reported error box is still consistent with the inverse Compton model. Such agreement also strongly suggests that most of the 2–10 keV soft photons have the same primary origin as the power law comptonised photons >10 keV and do not come from a spatially detached region.

However, six data points are far from conclusive. We have selected 27 reported spectral measurements of hard X rays in the range ~20–≤200 keV with acceptable reported or apparent error margins (≤30% in α, see Table 2). Again we extrapolate all power law spectra down to 10 keV and up to 200 keV to obtain a uniform definition of L_h. Figure 1 plots observed L_h versus y. From equation (1) we expect an overall rise of L_h with y despite intrinsic variations in L_s. This is indeed borne out in Fig. 1. Of course, these data all have large experimental errors as well as detector sensitivity and limit differences. But any systematic bias is likely to be washed out by the large number of independent measurements. The qualitative increase of L_h with y in Fig. 1 is probably genuine and consistent with the inverse Compton model.

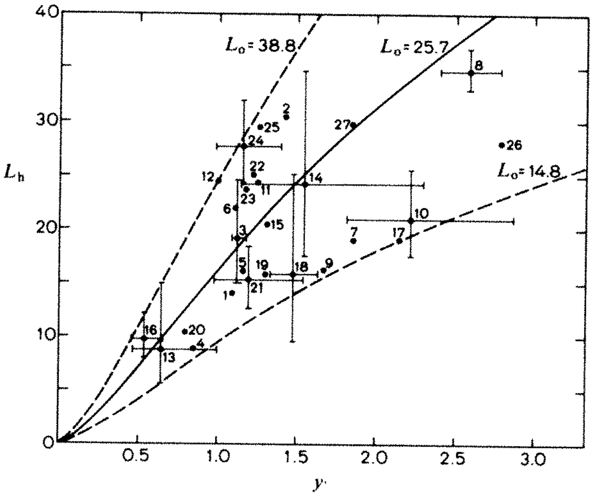

Fig. 1 Plot of L_h versus y listed in Table 2. Only a few sample error boxes are included for illustration. The solid curve represents weighted least square fit with function in equation (3). The dashed curves correspond to extremal values of L_0 sandwiching all data points. Numbers correspond to those in Table 2.

A closer look at the transition data also reveals that the variation of the combined luminosity from 2 to 200 keV is definitely correlated with y. From the limited data (Table 1 last column) we find empirically

$$(L_s + L_h) \cdot y^{-1/2} \cong \text{constant} \equiv L_0 \qquad (2)$$

This behaviour is consistent with the theoretical prediction that the accretion rate of a thin disk $\dot{M}$ onto a black hole varies as $\dot{M} \sim \text{constant} \times y^{1/2}$ because of the transonic nature of the radial drift. This result is discussed in detail elsewhere[9]. If equation (2) is valid universally then we should have (see equation (1))

$$L_h = L_0 y^{1/2}(1 - e^{-y}), \quad L_0 \approx \text{constant for } y \leq 1.5 \qquad (3)$$

A least square fit of the data with this function gives $L_0 = 25.7$ (Fig. 1). More significantly, all data points lie within a narrow wedge corresponding to $14.8 \leq L_0 \leq 38.8$ despite the wide range of L_h and y (Fig. 1).

Because of the crude nature of our data analysis and lack of calibration standard for the measurements made by different groups at different times, the above results must be viewed with extreme caution. Despite such uncertainties, the data suggest that, at least qualitatively, (1) predictions of the inverse Compton model is verified, (2) (2–200 keV luminosity $L)/y^{1/2}$ varies only slightly despite large changes in L and y. We urge that future observations should try to monitor carefully the long term variation of L_s and L_h with y simultaneously.

Solar oscillations, stellar oscillations and cosmology

G. R. Isaak

Department of Physics, University of Birmingham,
Birmingham B15 2TT, UK

Two implications of the recent observations[1] of low angular, high radial overtones of the whole Sun are reported here. The first implication is that other main sequence stars are likely to be oscillating in similar modes and that precision spectroscopy as well as photometry from space is capable of detecting these oscillations, thereby extending seismology to stars. The second implication is a solar helium abundance $Y \leq 0.17$ with implications for cosmological models.

Recent observations[1] using the 769.9 nm resonance line of potassium of velocity oscillations of the whole disk of the Sun have resolved the broad 5-min oscillation peak into over 20 discrete spectral lines of amplitudes between 0.1 and 0.3 m s^{-1} and a nearly equal spacing of 67.80 ± 0.15 μHz. It can be readily shown that such global velocity studies could be extended to the brighter stars using large telescopes as flux collectors and such attempts have been already made[2]. Extension to fainter stars is likely to be possible using precision differential photometry from above the turbulence and variable transmission of the terrestrial atmosphere. For radial modes a rough measure of the expected photometric amplitude for a given velocity amplitude is provided[3] by $\Delta m_B \approx \Delta V/40$ where Δm_B is the blue magnitude amplitude and ΔV is the velocity amplitude in km s^{-1}. Thus for the Sun the quoted velocity amplitudes of individual frequency components imply fractional variations of 6×10^{-6} to 2×10^{-5}. Such precision has not as yet been achieved with ground-based telescopes but statistically such variations are apparently detectable at the 3σ level if more than 3×10^{11} and 3×10^{10} photons are counted or the equivalent charge is digitised. Such light fluxes are within reach of medium telescopes for stars brighter than 6 mag. Clearly, differential measurements on at

0028-0836/80/070644—02$01.00

least three stars will have to be made simultaneously to provide sufficient differential systematic stability and redundancy to identify the variable star from its comparison stars. Were the equivalent of the structure of the 5-min oscillation of the Sun to be found in stars a powerful tool of analysis of main sequence stars would become available.

The second implication follows from the interpretation of the mean spacing of 67.80 μHz with alternate $l = 0$ and $l = 1$ modes, of increasing radial order within the context of the standard model of the solar interior[4] or a model with a surface enhanced heavy element abundance[5]. Both models, if they are to agree with these observations, imply a mean heavy element abundance $Z \leq 0.004$ and a low solar neutrino flux ≤ 2.3 SNU, consistent within two standard deviations of the results of the most recent measurements[6]. The same observations and interpretation lead to a solar helium abundance of $Y \leq 0.17$, a value which agrees with that of the quiet solar wind[7]. It was already realised some 10 yr ago[8] that such a low helium abundance, among other possibilities, would lead to a solar neutrino flux consistent with the low values observed.

Thus three solar phenomena, namely oscillations, the particle wind and the neutrino flux are consistent with $Y \leq 0.17$. As hydrogen burning during the lifetime of the Sun would have increased the helium concentration and no processes are known which could have destroyed helium in the Sun, it follows that the helium abundance of the primeval material out of which the Sun formed was ≤ 0.17. This value is substantially below the mean of the values for Y obtained from other observations relating to the solar atmosphere or other objects in the Universe[9]. It is also substantially below the preferred value of current simple cosmological models[10–12] of some 0.25–0.27 even if one corrects the expectations for the new value of the neutron mean life[13]. It is possible that this model can be reconciled with a lower helium abundance by, for example, requiring sufficiently degenerate neutrinos[10–12].

A more unambiguous determination of the helium abundance of the deep solar interior may result from definitive observation and identification of the fundamental and low order radial modes of the Sun[14].

METEOSAT observations of diurnal variation of radiation budget parameters

R. W. Saunders & G. E. Hunt

Laboratory for Planetary Atmospheres, Department of Physics and
Astronomy, University College London, Gower Street,
London WC1E 6BT, UK

Preliminary estimates of the outgoing IR flux and albedo obtained at hourly intervals, during one day, using digital METEOSAT data are reported here. The diurnal variation of these parameters varied according to the surface or cloud type over which they were being measured. The albedo over the desert, and both high and low clouds, remained constant, but altered over the sea surface. The emitted IR flux was constant over sea surfaces and low clouds, but altered over the desert during the day, due to surface heating. These diurnal variations can introduce biasing errors into time averaged radiation budget parameters, derived from polar orbiter data.

Radiation budget measurements of the Earth's atmosphere/surface system can provide information about the driving mechanisms of the Earth's atmospheric and oceanic circulation systems. Until recently, global radiation budget measurements have only been made from satellites in polar orbits[1–4,9] which sample specific areas of the Earth approximately once every 12 h. Because of the long time interval between samples and the restriction that these parameters are measured for approximately the same solar zenith angle, various assumptions have to be made when calculating daily mean values from these measurements.

The planetary albedo is determined by comparing the reflected solar radiation (measured from the satellite) with the incident solar energy calculated from the solar constant. The daily mean is inferred from one single daylight measurement by assuming the albedo is not dependent on solar zenith angle and that the radiation is scattered isotropically from all surfaces. Both of these assumptions are not valid in certain cases, such as for large solar zenith angles over the poles and for 'sunglint' reflection from the ocean surface. Sunglint occurs on the part of the Earth's surface where direct reflection from the Sun is possible as viewed by the satellite.

Table 1 The diurnal mean radiation budget parameters estimated from Polar Orbiter and Geosynchronous Orbiter data (W m^{-2})

Surface/cloud type of target area	Location of target area	Actual mean calculated from hourly METEOSAT values	METEOSAT value at 0900 h	% Difference of 0900 h value from diurnal mean
		Outgoing flux (±30* W m^{-2})		
Over desert	26° N 14° W	319	328	+3%
Over ocean	26° N 15° W	315	314	+0%
Over cumulus cloud	15° S 6° W	300	301	+0%
Over thick cloud extending up to the tropopause	26° S 35° E	214	200	−7%
Albedo (±*0.05)				
Over desert	26° N 14° W	0.32	0.32	0%
Over ocean	26° N 15° W	0.09	0.07	−22%
Over cumulus cloud	15° S 6° W	0.39	0.47	+21%
Over thick cloud extending up to the tropopause	26° S 35° E	0.59	0.62	+5%
Net flux (±*50 W m^{-2})				
Over desert	26° N 14° W	−114	−122	7%
Over ocean	26 °N 15° W	−42	−42	0%
Over cumulus cloud	15° S 6°W	−53	−58	9%
Over thick cloud extending up to the tropopause	26° S 35° E	−49	−23	53%

* The uncertainties refer to the absolute value, not to the random errors.

The outgoing long-wave radiation will have a diurnal variation over cloud-free landmasses as the ground will be heated by the incident solar radiation during the day, increasing the emitted flux. Hence twice-daily measurements from polar orbiters will not give an accurate daily mean.

Data from satellites in geosynchronous orbits such as METEOSAT are now available. These satellites are at a fixed

0028–0836/80/070645—03$01.00

point above the Equator (0° lat and 0° long for METEOSAT) and record images of the entire Earth's disk once every 30 min. This allows the radiation budget parameters to be adequately sampled for an investigation into their diurnal variation. The images are at three wavelengths, visible (0.6–0.9 μm), IR (10.8–12.2 μm) and water vapour (5.8–7.2 μm). The visible and IR channels were used to determine the albedo and long-wave flux respectively. Initially four target areas were chosen with different surface/cloud types which would be expected to have differing diurnal radiative properties. These areas were 150 km square on the Earth's surface which represents an average over at least 650 pixel values. The four areas chosen are described in Table 1, and the two cloud-free areas are shown in Fig. 1.

The visible channel has no radiometric calibration although attempts are being made to provide one[5]. For this study, a calibration was obtained by assuming the planetary (or system) albedo over North-west Africa to be 0.26 (ref. 6) at local noon on 21 August 1978. This value was based on aircraft and surface measurements taken over the area on 4 September 1974. The seasonal variation in surface albedo noted by Rockwood and Cox[6] was further south than the area chosen for the METEOSAT measurements. However, a check was made by comparing planetary albedos measured from METEOSAT at local noon in April, August and November and no significant change in albedo was noted for these months. Knowing the incident solar radiation for the 21 August, and assuming that the surface/atmosphere reflects radiation isotropically, the radiometer responses can be calibrated in terms of reflected energy. The METEOSAT visible radiometer scales linearly with incident radiation intensity, so having obtained a calibration for one radiometer value, the planetary albedo for different areas can be estimated. When the data become available, it is hoped to improve this calibration technique by a direct comparison of METEOSAT images with NIMBUS 7 ERB data and GOES EAST (70° E, 0° N) data where the images overlap.

The long-wave flux was derived from the calibration given by ESA[7] which was based on a comparison between the spacecraft digital counts and measured sea-surface temperatures. An atmospheric transmission model used for the NOAA satellite data[1] converted the 11-μm radiance to total outgoing flux at the top of the atmosphere. Figure 2 shows how the albedo and outgoing flux varied during one day (5 November 1978) for each target area. The albedo remained fairly constant over the desert, but over the sea it increased markedly with increasing solar zenith angle. This is because the sea surface can be relatively smooth and so reflects more radiation at glancing angles[8]. In contrast, cumulus cloud has a vertical structure which will reflect more of the radiation at glancing angles back in the direction from which it came. The dense high cloud gave a variable albedo which was due to changes in its structure during the day. The long-wave flux over the land increased markedly around noon due to surface heating, whereas over the sea and low cloud, the flux remained essentially constant. For high level cloud, the outgoing flux was variable which would be due to changes in cloud top altitude and structure.

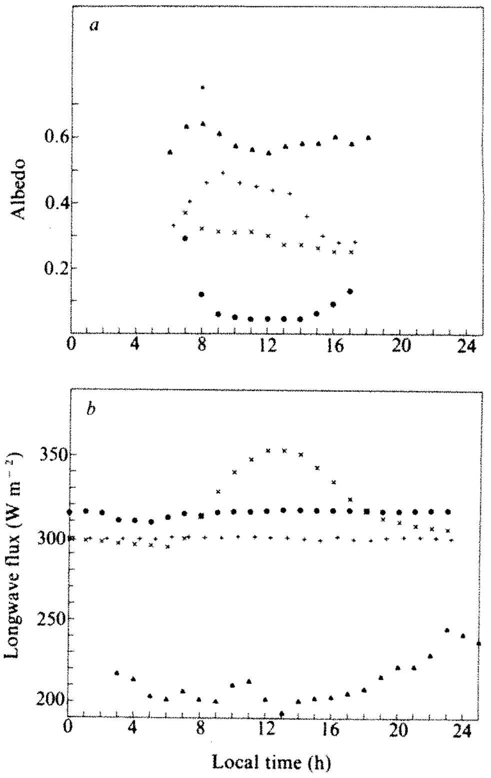

Fig. 2 The diurnal variation of albedo (*a*) and outgoing flux (*b*) as measured by METEOSAT over four surface/cloud types. ×, Over land; ●, over sea; +, over low Cu cloud; ▲, over high CuNb cloud. The absolute values of albedo and long-wave flux have an uncertainty of 0.05 and 30 W m^{-2} but the relative uncertainties will be much smaller.

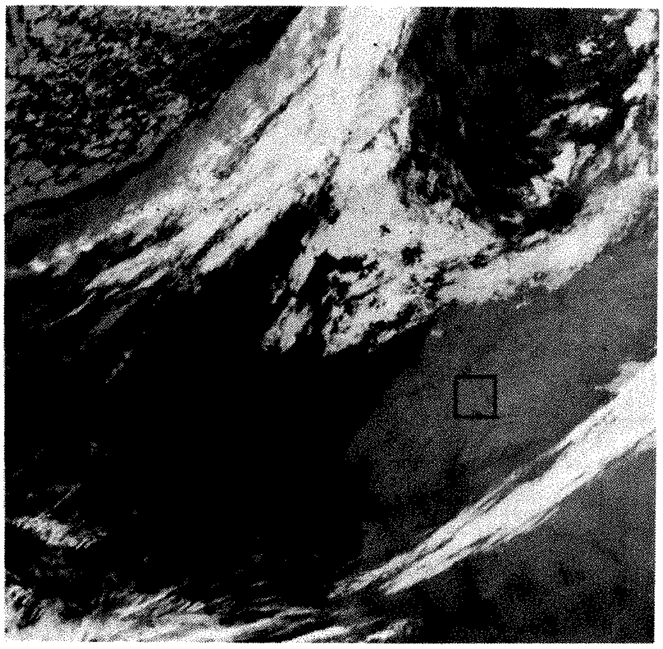

Fig. 1 The two cloud free target areas over NW Africa selected for the measurement of radiation budget parameters.

Table 1 illustrates the biasing errors, which can result from one single measurement taken from a polar orbiter; actual diurnal means are compared with the instantaneous 0900 h value using the METEOSAT observations. The latter value would correspond to the measurement made by a polar orbiter such as the NOAA series which passed over at a local time of 0900 h. The errors in the parameters, derived from the NOAA satellites, varied according to surface/cloud type. Long-wave flux errors are small and, as they only become significant over hot deserts, they are unlikely to affect the calculated global long-wave flux significantly. The albedo errors are more significant, especially as large areas of the globe are covered by ocean and low cloud; hence global albedos from polar orbiters would have a biasing error. To correct polar orbiter data sets, such as the one described by Gruber and Winston[9], the parameters over the ocean and low cloud should be corrected by the percentage differences listed in Table 1.

Also listed is the net flux which, being the small difference between two fluxes, has a large uncertainty. The errors are still present, although over the ocean, the errors are reduced because the albedo and outgoing flux errors are of opposite sign.

These results, taken from one day of METEOSAT data, show that biasing errors do exist in radiation budget parameters, obtained from polar orbiters. The geosynchronous satellite data, which are now available, allow correction factors to be determined when calculating diurnal, monthly and annual means from polar orbiter data.

Fossil charcoal as evidence of past atmospheric composition

M. J. Cope & W. G. Chaloner

Department of Botany, Bedford College, Regent's Park,
London NW1 4NS, UK

The presence of charcoal in the geological record offers a new approach to assessing oxygen levels in palaeoatmospheres. Charcoal is formed by the incomplete combustion of woody tissues. The combustion of wood is supported by the generation of the combustible gases carbon monoxide and methane during the pyrolysis process. As the combustion ranges of these gases are restricted with decreasing oxygen availability to a level below which no combustion will occur, the production of charcoal and its appearance in the geological column constitute a record of changing oxygen availability through time. We show here that the occurrence of charcoal in rocks from the Lower Carboniferous onwards suggests that atmospheric oxygen never fell below 0.3 of present atmospheric level (PAL) during this time. Detrital charcoal formed by forest fire must have contributed an appreciable fraction to inert carbonaceous matter in sediments (kerogen) during post-Devonian time.

Natural fires have been documented in grassland, tundra, boreal forest, deciduous forest and tropical evergreen forest ecosystems in North America[1,2]. In the southeastern US, fires are common in drought-dried peat[3]. Burning may also occur in dried strand-line accumulations of both aquatic and land-derived vegetation[4].

The fossil record of terrestrial plant life indicates that small, vascular plants with upright stems had colonised the land surface by the late Silurian (~400 Myr) and that by the close of the early Devonian there were land plants at least 1 m in height and 50 mm in diameter[5]. Such plants would have been capable of forming what could loosely be called reed-swamp, or brush vegetation in drier habitats. In conditions of drought such vegetation would presumably have been capable of supporting a fire, with associated charcoal production. By late Devonian time (~350 Myr) we have records of forest trees in excess of 1 m in diameter; at this stage, forest fires, comparable with those of the present day, would have been possible. We have no evidence of terrestrial vegetation capable of fuelling any natural fire before the close of the Silurian, but presumably, before the evolution of upright terrestrial plants, accumulations of aquatic plant (algal) debris on strand lines may have presented suitable fuel for naturally occurring fire. Sizeable algae, which could accumulate on a strand line, are known from the Ordovician onwards[6] (~500 Myr). However, such strand-line accumulations of algal material would surely not ignite readily by lightning strike, and we know of no published record of charcoal of pre-Devonian age.

Charcoalified plant fragments are locally abundant in many post-Devonian sedimentary sequences. They may be identified by silky lustre and friability in hand specimen and are characterised by high reflectance in polished rock sections. Such material is known as fusinite[7]; accumulations of fusinite clasts make up the coal macrolithotype fusain[8]. Fusinite clasts are typically fragments of wood, showing well preserved cellular structure, although more rarely leaves and other plant organs can be preserved in this way[9,10]. Certain features of cell wall structure revealed by scanning electron microscope examination are particularly characteristic of a pyrolysis origin[11]. Fine anatomical details of pits and wall thickenings are preserved in charred, woody tissues, but the original components of the cell wall (middle lamella, primary wall and secondary wall) lose their intrinsic identity on pyrolysis. This apparent homogenisation of the wall takes place above 300 °C and is observed in all charcoals over a wide range of geological ages (see Fig. 1). With normal coalification of woody tissue (that is, incorporated in sediment without previous charring) the middle lamella is still visible in structured plant material up to medium volatile bituminous rank of coal[12].

Charcoal results from incomplete combustion of plant tissues[13] and is a common product of natural wildfires (forest fires)[14]. Such burning has three essential requirements: (1) a suitable fuel, (2) an ignition source, and (3) the necessary level of atmospheric oxygen to support combustion. Suitable natural ignition sources are lightning strike, volcanic activity, meteorite fall, spontaneous combustion and sparks due to rock fall. Of these, lightning strike is the most important reported cause of naturally ignited fires. Some two-thirds of all forest fires along the west coast of the US may be attributed to this cause, and 1–2% of fires in the Florida Everglades are similarly ignited[15]. The frequency of lightning discharges is estimated at 100 s^{-1} over the surface of the Earth[16]. Direct evidence of lightning strike in the geological record is rare. However, Komarek[17] notes that a petrified specimen of *Taxodium* sp. from the Miocene of Florida displayed a typical lightning streak along its length. Fulgurites result from the fusion of siliceous material (quartz sands) by lightning discharge. They are common in present day desert areas[17] and are also known from older sediments[18].

The pyrolysis of wood associated with its combustion proceeds by the evolution of water, carbon dioxide, formic acid and

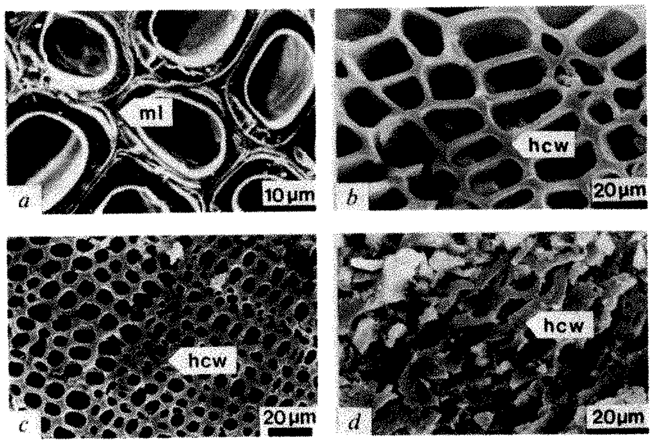

Fig. 1 Scanning electron micrographs of wood and charcoals. *a*, *Pinus sylvestris* wood showing the presence of the middle lamella between adjacent cells (ml) (scale bar, 10 µm) *b*, *c* and *d* (scale bars, 20 µm), fossil charcoals (fusinites) from the Tertiary Niederheinische Braunkohle, Jurassic Scalby Formation and Carboniferous Coal Measures respectively showing homogenisation of the cell wall (hcw) without a visible middle lamella.

0028-0836/80/070647—03$01.00

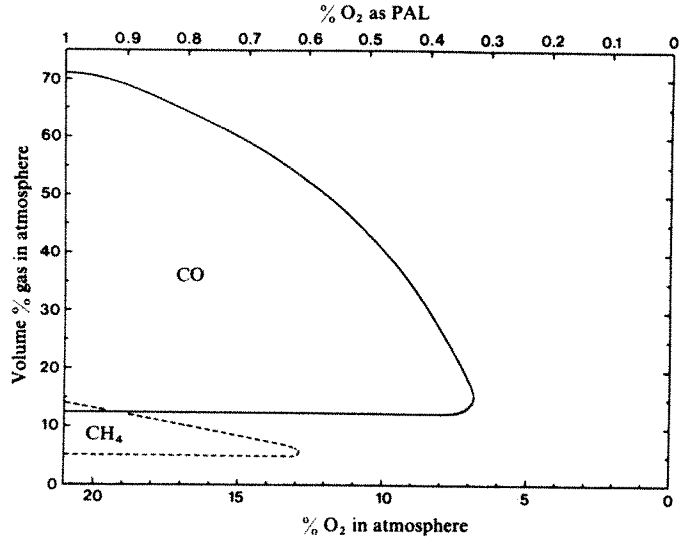

Fig. 2 Combustion ranges of carbon monoxide and methane for varying percentages of oxygen in the atmosphere (data taken from Coward and Jones[19]). As the combustion of these gases accounts for the burning associated with forest fire it is suggested here that the latter could not occur with ≤7% oxygen in the atmosphere; this corresponds to ~0.3 PAL.

acetic acid with increasing temperature up to 280 °C (ref. 13). Above this temperature, the combustible gases carbon monoxide and methane are released; it is the combustion of these gases which supports the flames constituting burning. The combustion ranges of carbon monoxide and methane are clearly defined with respect to the percentage by volume of combustible gas to air, and the limiting oxygen percentage in the atmosphere (see Fig. 2). Data from Coward and Jones[19] for combustion of various gases in air diluted by nitrogen indicate that combustion of carbon monoxide will not take place in an atmosphere with <6.8% oxygen; the corresponding figure for methane is 12.8%. It is also shown that with decreasing oxygen content of the atmosphere, the combustion range of each gas becomes more restricted. This means that at any stage of atmospheric evolution the occurrence of fire would have been limited by a threshold of oxygen availability.

Oxygen is believed to have been absent from the Earth's early atmosphere. The absence of oxygen in volcanic emissions has led to the suggestion that the accumulation of oxygen in the early atmosphere has been either by photodissociation of water in the upper atmosphere[20] or from photosynthesis by plants. Proponents of both theories recognise that oxygenic photosynthesis had become the most important oxygen producer by Phanerozoic time. Berkner and Marshall[21], favouring an initial photosynthetic build up, see a progression from 0.01 PAL of oxygen in the Cambrian to 0.1 PAL in the Silurian, and to more than PAL with the appearance of abundant land plant life in the Devonian and Carboniferous. Other workers place less emphasis on the contribution of oxygen by land plants, and stress the importance of the phytoplankton contribution. Tappan[22] sees oxygen levels from this source as ~0.3 PAL in the Cambrian, more than PAL from Ordovician to Devonian, <0.1 PAL in the Permo–Triassic and fluctuating above and below PAL for the rest of the Phanerozoic. Estimates of oxygen levels in the Phanerozoic of Berkner and Marshall, and of Tappan, are shown in Fig. 3 together with base lines for carbon monoxide and methane combustion. (The limiting oxygen percentages for combustion of carbon monoxide and methane can be seen to correspond to ~0.3 PAL and 0.6 PAL respectively.) The carbon monoxide combustion threshold is necessarily the base line for natural burning, and therefore, charcoal production. Based on Tappan's estimate, charcoal could not have been produced from late Carboniferous to early Jurassic times. However, fusain bands and lenses are widely distributed in Northern Hemisphere Carboniferous bituminous coals[23], and in northern Europe there is abundant clastic fusinite in Rhaeto–Liassic and Middle Jurassic sediments[24–26]. Clearly, Tappan's estimates of oxygen levels based on phytoplankton production are incompatible with this evidence, while the Berkner–Marshall oxygen curve is above the carbon monoxide combustion threshold from the mid-Devonian onwards, and is, therefore, consistent with the geological record of fusinite. A different view is adopted by Cloud[27], whose estimate of oxygen levels is based on an assumption of steady accumulation of photosynthetic oxygen throughout geological time. Cloud argues that the Pasteur point (0.01 PAL) was attained early in the Earth's history (~2,000 Myr) and that levels of 0.1 PAL were reached in the late Precambrian. From his data the carbon monoxide combustion threshold would have been achieved by the late Cambrian, which is consistent with the geological record of fusinite.

The presence of the first charcoal in the geological record is an indication that oxygen levels in the atmosphere were above 0.3 PAL. The oldest sedimentary occurrences of charcoal largely in a non-carbonaceous matrix that we know of are in Lower Carboniferous strata from Donegal, Eire[28], and Fife,

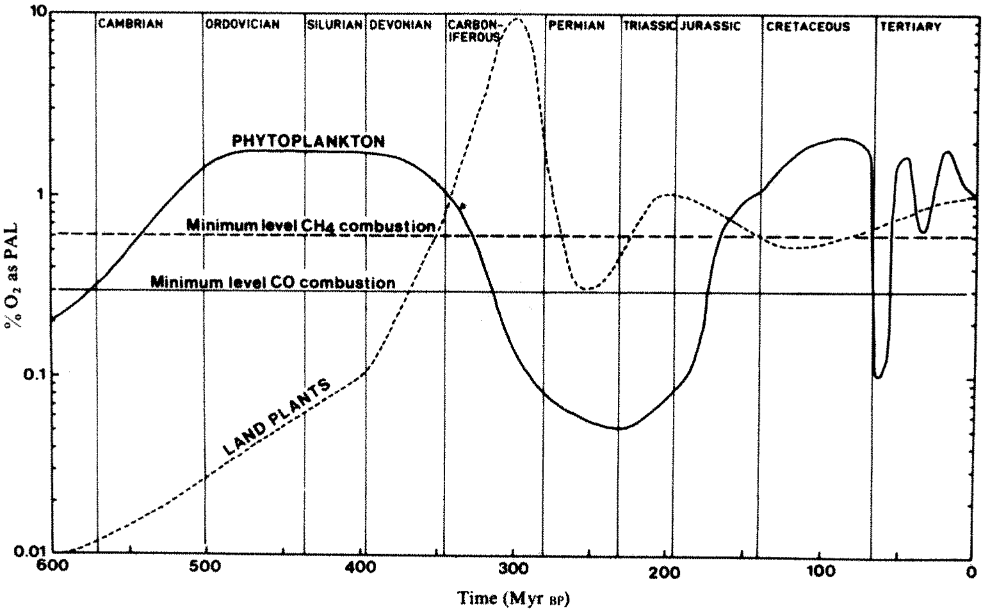

Fig. 3 Estimates of the level of oxygen in the atmosphere during Phanerozoic time based on the assumption that photosynthesis by phytoplankton was the main controlling factor[22] (solid line) and corresponding hypothetical levels assuming land plant photosynthesis to be the main controlling factor[21] (broken line). The estimate of Cloud[27] based on a steady build-up of oxygen level from all photosynthetic sources is not shown for reasons of clarity; this gives oxygen levels above 0.1 PAL at the start of the Phanerozoic and above 0.3 PAL by the late Cambrian, with a subsequent steady increase to PAL during the remainder of the Phanerozoic. The combustion thresholds for carbon monoxide and methane[19] which necessarily limit the occurrence of forest fire burning, are also shown.

Scotland. The oldest documented record of charcoal in a carbonaceous matrix is from a transitional Devonian–Carboniferous 'coal' from Pennsylvania[29]. In the present state of knowledge, it can therefore be argued that levels of oxygen greater than 0.3 PAL were attained at least by the latest Devonian and were subsequently maintained above this level. Thus the recognition of charcoal in sediments offers a useful quantitative indicator of the oxygen content of the atmosphere from the Devonian onwards.

Charcoal has a particular significance in another respect as a constituent of sedimentary rocks. Its inert character renders it highly resistant to microbiological or chemical degradation during sedimentation and subsequent diagenesis, while its thermal stability enables it to withstand high palaeotemperature of deep burial. It follows that from Devonian time onwards, charcoal could have made a significant contribution to the insoluble dispersed organic matter in sediments (kerogen). The total amount of kerogen is estimated to be some 500 times greater than all known coal deposits[30]. However, because of its dispersed nature, this vast reservoir of carbonaceous material is unlikely to be exploited despite the ever increasing need for new fuel sources. Natural burning produces air-borne carbon particles[31] and releases charcoal clasts at the site of fires[14]. Such inert carbonaceous products can contribute to kerogen. Air-borne carbon particulates are recognised in modern and Tertiary marine sediments[31,32], and structured fusinite micro-clasts occur in kerogen isolated from ancient sediments[33]. A study of these kerogen particulates in post-Devonian sediments may help to establish the geographical and temporal distribution of pyrolysis-derived components and thus reveal a record of past forest-fire activity.

Charcoal has been largely overlooked or ignored by both sedimentologists and palaeobotanists in sediments of all ages (except, perhaps, coals); in view of the geochemical and palaeoecological significance of its occurrence, attention could usefully be concentrated on the first appearance of charcoal in the geological record. We would be particularly interested to learn of any charcoal occurrences of Devonian or earlier age.

Stable isotope and sea-level data from New Guinea supports Antarctic ice-surge theory of ice ages

Paul Aharon, John Chappell & William Compston

Institute of Advanced Studies,
Australian National University, Canberra, Australia

Two theories of glaciation have received considerable attention, the Milankovitch orbital theory[1,2] in which climatic change is ascribed to latitude-dependent variations in solar radiation that accompany changes in the Earth's orbital parameters, and the Antarctic surge hypothesis[3–6], in which a large Antarctic ice sheet 'surges' into the Southern Ocean thereby increasing the Earth's albedo, and the resultant cooling triggers the growth of ice in the Northern Hemisphere. The interval which encompasses the peaks of the last interglacial maximum at ~125 kyr (ref. 7) and its subsequent decline, with cooling of the North Atlantic[8] and rapid fall of sea level[9,10], presumably also includes the event that triggered the succeeding ice age. The raised coral reefs of Huon Peninsula, Papua New Guinea, contain a particularly good record of the interval 140–105 kyr (ref. 11), from which we present oxygen isotope and sea-level data which seem to require an Antarctic surge at 120 kyr, and which also have a bearing on the role of the Milankovitch factor.

The structure of Huon Peninsula reefs VIIa, VIIb and VI is shown in Fig. 1. Relative to the rising landmass, the essential sea-level changes represented by these reefs are [10,11]: (1) sea-level rise during building of reef VIIa; (2) minor fall during erosion at X in Fig. 1; (3) rise of >8 m during building of VIIb crest; (4) falling sea level, with continued growth of the patch-reef at Y during early stages; this regression eventually reached the base of reef VI; and (5) rise during building of reef VI. The envelope curve of sea-level changes interpreted from these and comparable reefs in Timor[9] is shown in Fig. 2*a*; the tectonic uplift factor has been subtracted[11–13]. Chronology is based on ^{230}Th/^{234}U determinations of these reefs[12,13], correlated with dated reefs in Timor where VIIa, VIIb equivalents are separated clearly[9]. Correlation extends to well dated reefs in Hawaii[14] which contains two units believed equivalent to VIIa, VIIb on the grounds that each reef-building phase essentially is controlled eustatically[9]. Pooling the ^{230}Th/^{234}U data puts VIIa at 133 ± 4 kyr and VIIb at 120 ± 3 kyr (ref. 9). Reef VI dates at 105 kyr and correlates with similar reefs in Timor[9] and Barbados[15]. The duration of building and emergence of VIIb are important in our subsequent discussion. First, between erosion unconformity X in Fig. 1 and the VIIb crest there is >8 m of

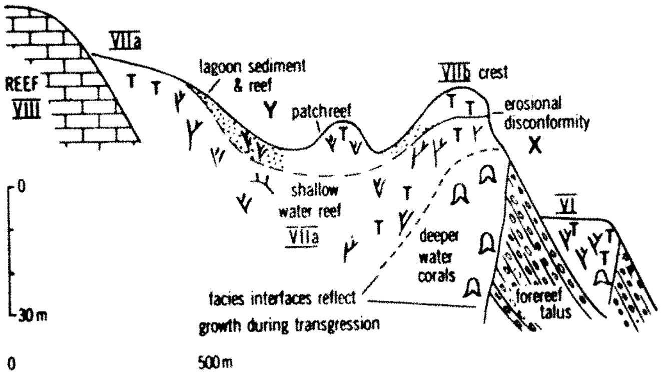

Fig. 1 Section of New Guinea reefs VIIa, VIIb, VI generalised from three separate sections (Gitua, Sazum, Sialum[11]). Sampling points shown by *Tridacna gigas* symbol (T).

shallow water reef, representing 1–2 kyr of growth, on the basis of ^{14}C study of Holocene reef growth at the Huon Peninsula[16]. Second, between emergence of VIIb crest and cessation of coral lagoon–reef growth at points Y in Fig. 1, ~3 kyr minimum must have elapsed assuming both tectonic and glacio–eustatic factors acted at maximum known rates[10,11].

Stable isotope analyses from these reefs were based on the giant clam *Tridacna gigas*, for the following reasons. (1) Coral recrystallisation in the raised reefs is extensive and diagenetic exchange of carbon has been confirmed by ^{14}C analysis rendering corals unsuitable[17]. (2) Hermatypic corals fractionate stable isotopes in a manner related to growth habitat[18,19]. (3) The massive aragonite shell of *Tridacna gigas*, readily checked for diagenesis by microscope and X-ray diffraction methods, is shown by ^{14}C generally to remain immune from carbon exchange and diagenesis[17]. (4) Most importantly, our analyses of modern specimens indicate temperature-controlled isotopic equilibrium with surrounding seawater. Table 1 lists $\delta^{18}O$ for 23 determinations from seven modern specimens as -1.54 ± 0.19‰ PDB. The adjacent ocean yields -0.07‰ SMOW; using Epstein's[20] palaeotemperature equation plus 0.6‰ aragonite enrichment factor[21] gives an isotopic temperature of 27 °C, which agrees with measured sea-surface temperatures in the area.

Stable isotope data from each reef phase are given in Table 1, together with estimated sea-level and mean age data. Multiple samples (numbers as given) were collected in each reef zone and multiple determinations made of each. The procedure was as follows: to measure the environmental average it is necessary to sample the full growth-width of a *Tridacna*, as stable isotope analysis of single growth lamellae in modern specimens clearly shows season-dependent variation[22]. Accordingly, the massive hinge region was sliced radially and each slab scrutinised for algal borings and calcite veins. Flawed samples were rejected. A thin strip extending across each slab was crushed, X-rayed to ensure aragonite purity, and the powder roasted for 30 min at 400 °C to eliminate any possible organic shell material[20,23]. Extraction of CO_2 follows McCrea[24], and mass spectrometry was done on a modified MS-12 machine[25]. Instrument precision is ±0.05‰, reproducibility including chemistry is ±0.1‰.

Almost all samples grew in reef sites exposed to the open ocean, either in forereef or shallow reef crest positions. The only exceptions are those from the regression phase of VIIb (Table 1), which come from the patchreef and lagoon floor at Y in Fig. 1. Oxygen isotopes show significant variations across the interval 140–105 kyr, while the carbon isotopes do not. $\delta^{13}C$ shows no significant variation, first because its temperature dependency is three (ref. 26) to six (ref. 27) times smaller than for $\delta^{18}O$, and second because it has greater intrinsic variability related to local and diurnal $\delta^{13}C$ variations measured in the coastal waters[22].

Concerning the $\delta^{18}O$ variations, two factors are important for organisms in well mixed ocean waters. Temperature rise of 1 °C lowers $\delta^{18}O$ by about 0.24‰; glacio–eustatic sea-level rise of 10 m lowers $\delta^{18}O$ by ~0.1‰ due to dilution of oceanic oxygen by ^{18}O-poor ice meltwater[28]. These two factors are decoupled in Table 1 as follows. The difference between the modern *Tridacna* $\delta^{18}O$ value (-1.54‰) and that for a given reef phase is treated as if it were due to sea level being different from present, giving the $\delta^{18}O$ sea-level estimates of Table 1. Should this apparent sea level be significantly different, statistically speaking, from the sea level previously established for that reef phase then the 'unexplained' $\delta^{18}O$ residual is taken as being temperature related, for example, for reef crest VI (line 2, Table 1), $\delta^{18}O = -1.45$‰ difference from modern $= -0.09$‰, giving an apparent sea level of −9 m. This is not significantly different from the estimated sea level of −14 m.

In this way, only reef VIIb crest shows a $\delta^{18}O$ value which is not explicable in terms of sea-level change. It is 0.41‰ higher than modern; more importantly, it is 0.51‰ higher than the value for VIIa crest, which formed at a similar sea level 5–7 m higher than present (Table 1). This $\delta^{18}O$ difference is significant at better than 0.01 level (Student's *t*-test), and the difference lies between 0.40‰ and 0.62‰ at the 95% confidence level. As the sea level cannot account for this difference, we conclude that the ocean adjacent to Huon Peninsula was 1.7–2.5 °C cooler during VIIb crest building than for VIIa crest.

Cooling during VIIb crest building follows a sea-level rise of >8 m which commenced at least 1–2 kyr previously (discussed above). This agrees qualitatively with the Antarctic surge theory, which predicts both rapid sea-level rise and significant world cooling before onset of the northern glaciation. Note that the Milkankovitch factor cannot explain this cooling, as radiation 120 kyr ago was similar to the present (Fig. 2*c*), and in any case our *Tridacna* samples measure mean annual conditions, which do not vary significantly in Milankovitch terms.

We stress that our samples from reef VIIb formation, which indicate this cooling during the sea-level rise at 120 kyr, come from the seaward side of barrier reefs which were distant from river mouths and fully circulated by open sea. This 2 °C cooling poses a quantitative problem, if it reflects the arrival in the New Guinea region of cold water originating from an Antarctic surge. If all the heat for melting the floating ice came from the entire oceans (latent + sensible heat), net cooling would be only 0.3 °C. Either there is a more direct transfer via some component of the oceanic circulation, or global cooling arising from the extended iceshelf albedo is implicated. We note that the cooling effect seems largely to have disappeared in the tropical New Guinea

about 3,000 yr after the VIIb peak, that is, when the VIIb patch reefs formed (point Y in Fig. 1), as temperatures similar to present are indicated (Table 1). (Although this result is from samples which grew within, as against outside, a lagoon, we believe lagoon ponding was not involved as the geometries are similar to modern, fully flushed lagoons at Huon Peninsula.) Hence, irrespective of the mechanism which produced the 2 °C cooling during the VIIb sea-level rise, it seems that its manifestation waned in the tropics while the northern glaciation was initiated. We do not know whether the surging ice mass was more likely to have been East Antarctica (Wilson hypothesis[3,4]) or West Antarctica (Mercer hypothesis[5,6]).

Note also that the Milankovitch factor predicts strong warm-summer–cool-winter contrast during the 125–130 kyr interval, a condition normally taken as inimical to northern continental ice growth. Such a radiation pattern may favour enhanced summer snowfall in Antarctica, leading to icesheet building towards instability. This might explain the minor sea-level decline from the VIIa peak before the VIIb rise. Figure 2*d* summarises the sequence of events, and we conclude that an Antarctic ice surge seems likely to have initiated the last glaciation.

We thank the people of the Tewae subdistrict, Papua New Guinea, for logistic help and hospitality. This study is supported by an ANU Scholarship to P.A.

Isostatic equilibrium grounding line between the West Antarctic inland ice sheet and the Ross Ice Shelf

Larry L. Greischar & Charles R. Bentley

Geophysical and Polar Research Center, University of Wisconsin-Madison, Madison, Wisconsin 53706

The Ross Ice Shelf is widely believed to be a Holocene feature, that is, during the late Pleistocene the inland (grounded) ice sheet extended out nearly to the continental shelf break in the Ross Sea, and retreated to its present position between 5,000 and 10,000 yr BP. If so, and if the grounded ice sheet remained in that position for at least 10,000 yr, then a sea floor uplift of the order of 100 m is still to be expected in the grid western part of the Ross Ice Shelf. Even for a smaller and more ephemeral extension of the grounded ice, the uplift would still be several tens of metres. Recently reported measurements indicate that there are extensive areas near the present grounding line where the water layer beneath the ice shelf is thin enough so that uplift would lead to a grounding line advance of at least 100 km. As the sea floor depth generally increases towards the grid east, however, the maximum extent would not be past the middle of the present Ross Ice Shelf.

Seismic soundings of submarine topography and radar soundings of ice thicknesses were made at sites on a 55 km grid covering the Ross Ice Shelf, Antarctica, during the Ross Ice Shelf Geophysical and Glaciological Survey (RIGGS)[1–5]. The submarine topography, characterised by a general deepening to

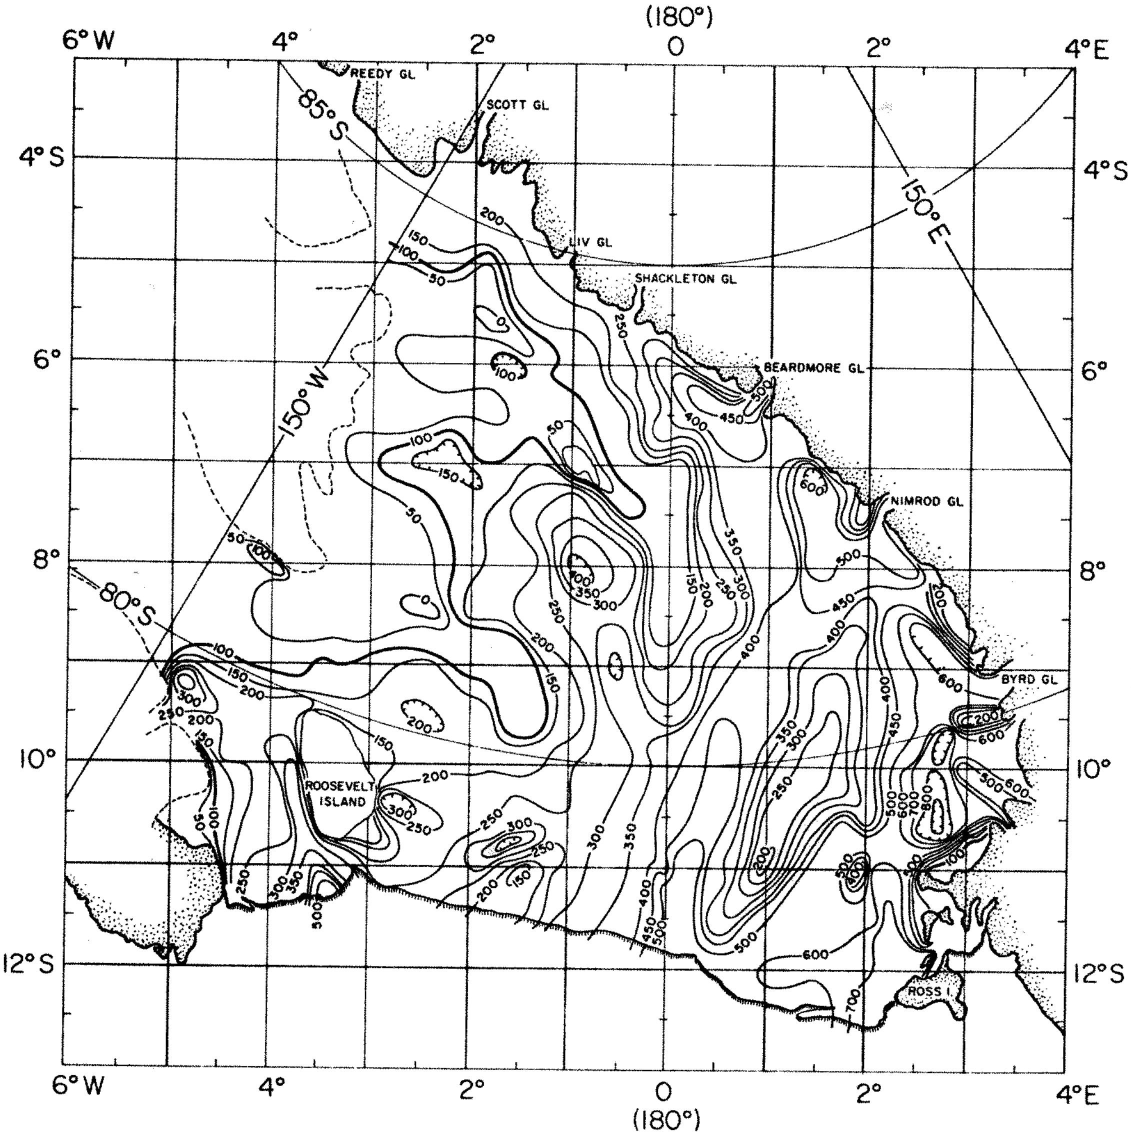

Fig. 1 Water depth beneath the Ross Ice Shelf. Standard grid coordinates are shown; grid north is towards Greenwich, and grid meridians are parallel to 180° W longitude. The present grounding line between the Ross Ice Shelf and West Antarctica is shown by the dashed line which is discontinuous in areas where ice streams enter the ice shelf. The contour interval is 50 m for depths from 0 to 500 m, and 100 m for greater depths.

the grid eastwards on which is superimposed a curving ridge–trough system, is reflected in a contour map of the 'water depth' (defined as the thickness of the water layer beneath the ice shelf) (Fig. 1). The position of the primary grounding line between the Ross Ice Shelf and West Antarctica was determined from airborne radar sounding measurements of ice surface elevations and strength and polarisation of bottom reflections[6]; the latter indicate whether water or rock is present directly below the ice. Seismic, radar and altimeter measurements made on the surface[1–3] were used for control. The surface topography shows the grounding line to be deeply indented beneath the West Antarctic ice streams, although scattering of the radar signals by heavy crevassing prevents accurate determination of its position. The ice shelf is also grounded at Roosevelt Island (grid position 10.0° S, 3° W), Crary Ice Rise (7.0° S, 1.0° W), near the Steershead Crevasses (8.5° S, 2.5° W), and possibly at RIGGS station F7 (5.5° S, 1.8° W) (see Fig. 3). Beneath much of the grid western part of the ice shelf, the water depth is < 100 m, and in some places it is only a few tens of metres.

Stuiver *et al.*[7] have reconstructed the Antarctic Ice Sheet at the 18,000 yr BP glacial maximum. Their reconstruction indicates that West Antarctic ice was then ~2,500 m thick near the present grounding line, and that the margin coincided with a line of sills parallel to the edge of the Ross Sea continental shelf. Two-by-two-degree mean isostatic gravity values at RIGGS stations on the Ross Ice Shelf[8], which are as much as 15 mGal negative compared with a fourth-order satellite gravity field[9], strongly suggest that glacio–isostatic depression of the grid western part of the present Ross Ice Shelf area still remains. Recent evidence from Ross Sea cores also suggests that grounded ice reached the continental shelf margin during the late Pleistocene[10]. Thomas and Bentley[11] calculated that if such a Ross Ice Sheet existed 18,000 yr ago, then it probably retreated rapidly to its present position between 13,000 and 7,000 yr BP. Geological data in the McMurdo Sound and dry valley areas yield minimum ages of ice retreat ranging from 3,000 to 10,000 yr BP (ref. 12) and have further been interpreted as showing that the grounding of the ice sheet occurred more than 47,000 yr ago[13].

Although some recent analyses of marine and glacial geological evidence indicate that only minor expansions of the grounded ice occurred during the Quaternary[14–16], we believe that the preponderance of evidence favours the existence of an extended grounded ice sheet of some form. The following analysis is based on the initial working hypothesis that a grounded 'Ross Ice Sheet' existed long enough to become isostatically compensated (~10,000 yr), and that it was removed rapidly between 5,000 and 10,000 yr BP. In that case, isostatic uplift of the loaded area should still be occurring. The grounding line between the West Antarctic Ice Sheet and the Ross Ice Shelf will advance as the sea floor rises. We have estimated the uplift remaining in the grid western portion of the Ross Ice Shelf, assuming a former ice thickness of 2,500 m (ref. 7). Following Bennett[17], we take unloading to have been instantaneous, and assume a simple exponential model of uplift:

$$Z = Z_0 \exp[-(t-t_0)/t_r] \quad (1)$$

where Z is the amount of uplift remaining, Z_0 is the original isostatic depression due to the ice load, t_0 is the time of load removal and t_r is the time constant of isostatic rebound. Z_0 can be estimated from the former ice thickness, T, and the estimated average depth of the present sea floor, $\bar{D}$, by

$$Z_0 = \frac{\rho_i}{\rho_m} T - \frac{\rho_w}{\rho_m}(\bar{D} - Z) \quad (2)$$

where ρ_i, ρ_w and ρ_m are densities of ice, sea water and mantle rock, respectively. Substitution of equation (2) into equation (1) yields an expression for the remaining uplift:

$$Z_p = \frac{\left[\frac{\rho_i}{\rho_m} T - \frac{\rho_w}{\rho_m} \bar{D}\right] \exp[-(t_p - t_0)/t_r]}{1 - \frac{\rho_w}{\rho_m} \exp[-(t_p - t_0)/t_r]} \quad (3)$$

wherein Z_p and t_p are the present remaining uplift and the present time.

The average water depth at RIGGS stations, $\bar{D}$, is ~650 m. The relaxation time constant, t_r, was estimated for an area the size of the Ross Ice Shelf from values measured in the Northern Hemisphere and predicted by model studies (Fig. 2, adapted from Cathles[18]). The linear dimension of the Ross Ice Shelf is of the order of 1,000 km, so t_r was chosen to be ~4,400 yr, the value used by Cathles for central Fennoscandia. Note that t_r is relatively independent of both the linear dimension of the ice load and the crustal rigidity for ice loads of this size. Densities used in equation (3) were $\rho_i = 0.91$ Mg m^{-3}, $\rho_w = 1.03$ Mg m^{-3}, and $\rho_m = 3.33$ Mg m^{-3}.

The results of the calculation (Table 1) show a remaining uplift ranging from 50 to 170 m. This estimate agrees well with that from the mean isostatic gravity anomalies which suggest as much as 150 m residual depression near the grounding line[8]. Because of the linearity of equation (1), these figures can easily be modified to fit other assumptions. Thus, for example, if the initial depression were only half as large as has been assumed, the uplift remaining would still be at least 50 m if the time since removal is less than 7,000 yr. That initial depression, in turn, could correspond to a fully compensated grounded ice sheet whose margin extended only about as far as a line extending from Edward VII Peninsula to Byrd Glacier, to a fully extended ice sheet which was in position for only ~3,000 yr, or to a 'low profile' extended ice sheet that might be compatible with the shape of internal reflecting horizons found in the West Antarctic interior[27]. Thus 50 m is a reasonable approximation to an uplift to be expected even assuming a smaller or more ephemeral ice sheet.

Table 1 Uplift remaining since ice removal

Time since ice removal (yr)	Remaining uplift (m)
5,000	170
6,000	135
7,000	105
8,000	80
9,000	65
10,000	50

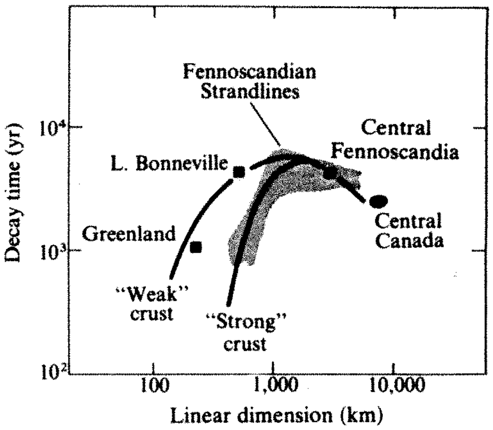

Fig. 2 Decay time constant for isostatic uplift versus the linear dimension of areas formerly covered by ice sheets (Canada, Greenland, Fennoscandia) or water (Lake Bonneville). Adapted from Cathles[18].

We have, therefore, estimated a maximum and minimum predicted advance of the grounding line based on a remaining uplift of 50–170 m and the assumption that the ice shelf thickness remains constant at the grounding line (Fig. 3). The maximum predicted grounding line extends grid northeastwards across the ice shelf from the seaward end of Roosevelt Island, and is deeply indented by extensions of the present ice streams. The minimum predicted grounding line advance would result from an advance of the central part of the present grounding line, with additional minor advances occurring near Edward VII Peninsula, Roosevelt Island and Crary Ice Rise.

The present rate of uplift is, from equation (1):

$$\left.\frac{dZ}{dt}\right|_{t=t_p} = -\frac{Z_p}{t_r} \quad (4)$$

for $Z_p = 110$ m, the uplift rate is 25 mm yr^{-1}. Division by the water depth gradient, which varies from 10^{-4} to 10^{-3} near the present grounding line, yields a rate of advance of the grounding line of 25–250 m yr^{-1}. At this rate, several thousand years would be required for the grounding line to advance to its predicted maximum position. As uplift occurs, however, points seaward of the primary grounding line will be pinned on high points of the sea bed, forming new ice rises. Compressive strains upstream from these pinning points will greatly accelerate the rate of grounding line advance. We believe this is now occurring upstream of Crary Ice Rise (grid 7.0° S, 1.0° W)[19], and also near the Steershead Crevasses (grid 8.5° S, 2.5° W).

The possibility that sedimentation may have been an important factor during isostatic adjustment can be dismissed on the basis of ocean floor cores taken at station J9 (grid 7.5° S, 1.5° W). Little or no Pleistocene or Recent sediment is present at that location[20], whereas a sedimentation rate of the order of 55 mm yr^{-1} would be required to produce a present state of isostatic equilibrium[17]. Furthermore, even if the basal layers of the ice shelf contain as much as 10% morainal material, the latter sedimentation rate would imply a bottom melt rate of ~0.5 m yr^{-1}, whereas temperature and resistivity measurements indicate a near-zero melt-freeze rate at J9 (ref. 21). Also, preliminary observations on ice cores from the lowest layers, obtained at J9 in December 1978, suggest an average bottom freezing rate of ~0.03 m yr^{-1} (J. W. Clough and I. A. Zotikov, personal communication).

Peltier[22] has pointed out that the longest wavelength components of the depression may 'feel' the Earth's core, and decay non-exponentially. On any realistic Earth model, however, that applies only to wavelengths of many thousands of

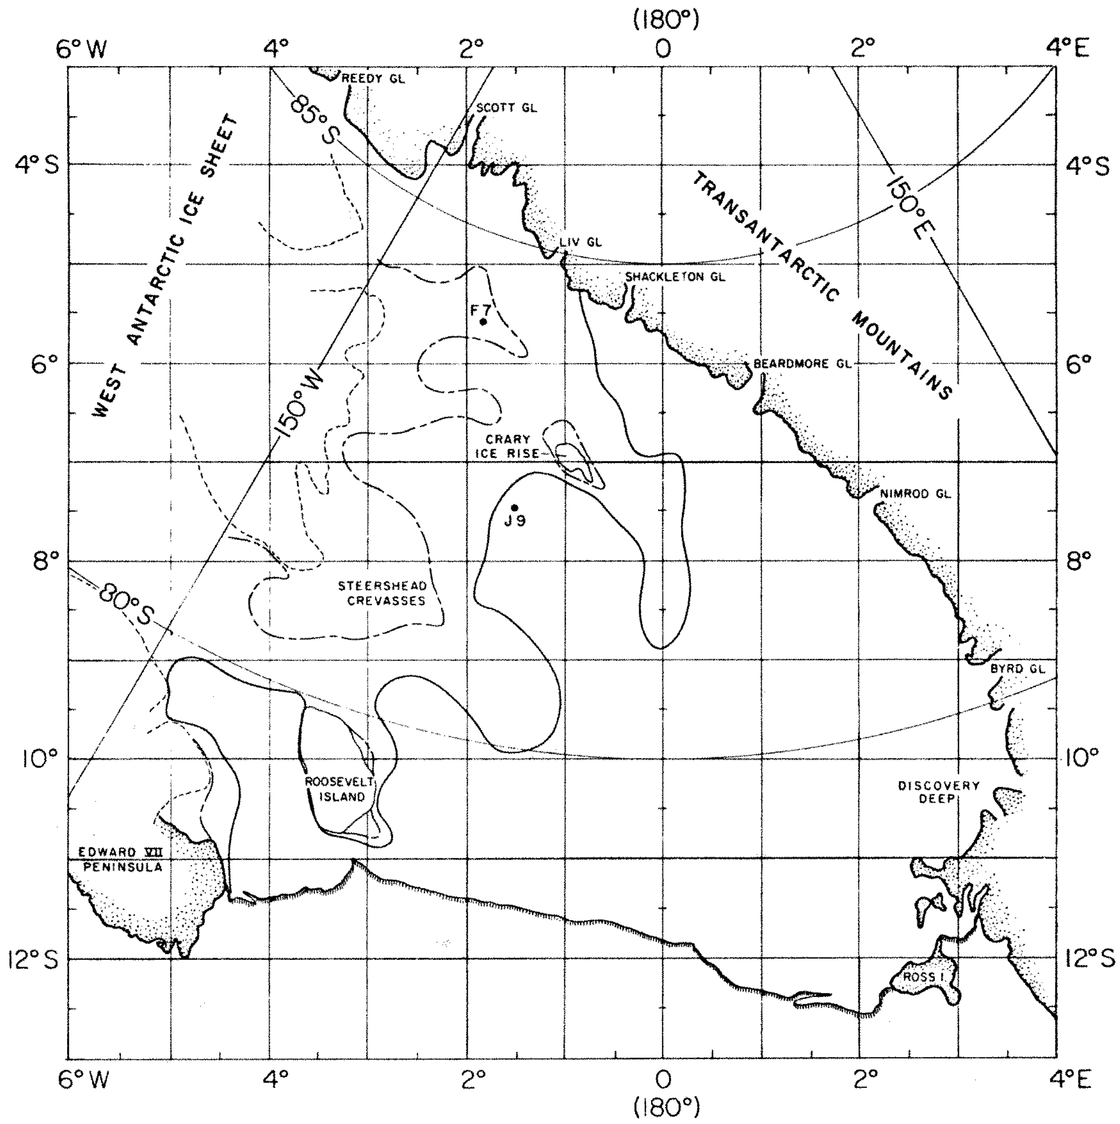

Fig. 3 Minimum (dashed line) and maximum (solid line) predicted seaward advance of grounding line, based on 50–170 m of additional isostatic uplift.

kilometres—much larger than the Ross Ice Shelf. Using Peltier's[22] Green functions in the Farrell–Clark[23] model and the Stuiver *et al.*[7] Antarctic reconstruction, Lingle and Clark[24] have computed a relative sea-level curve for 2,000 yr BP to the present near the centre of the Ross Ice Shelf. As their curve indicates a rate of emergence (~11 mm yr^{-1}) that is nearly constant rather than exponentially decreasing with time, it is impossible to use their method at the current stage of development to estimate the remaining uplift. Furthermore, as exponential decay describes well the uplift data from central Canada[25,26], it seems to be a reasonable assumption for uplift of the sea floor beneath the Ross Ice Shelf.

The model presented here does not, of course, consider the possibility of non-equilibrium of the West Antarctic ice sheet. Growth or shrinkage of that ice sheet due to climatic or inherent dynamic causes could produce grounding line movement which is large compared with that from isostatic uplift. However, if the West Antarctic inland ice sheet is approximately in steady state, an advance into the Ross Ice Shelf is still to be expected. The corresponding lowering of world sea level would be of the order of 0.5 m.

Widespread episodes of stream erosion during the Holocene and their climatic cause

G. Robert Brakenridge

Department of Geosciences, University of Arizona, Tucson, Arizona 85721

Quaternary fill-terrace sediments along a 6-km reach of the Pomme de Terre River in south-central Missouri (38°06′ N, 93°26′ W) have yielded abundant vertebrate fossils, pollen, and archaeological remains[1]. Numerous radiocarbon dates have also been obtained. When these are combined with stratigraphic results (described by Haynes and myself), an 'alluvial chronology' of floodplain depositional history can be constructed. The Holocene portion of this chronology is summarised here and compared with other dated alluvial and proxy-climatic sequences from the northern mid-latitudes. From such a comparison, considerable insight may be gained into the operation of synoptic climatological controls over fluvial sedimentation and erosion.

The state of our current knowledge on the floodplain history of the Pomme de Terre River is given in Fig. 1 which shows a plot, on an *x*–*y* coordinate system, of the sample elevations above local river level of 21 radiocarbon dates, and also the measured elevations of the tops and bottoms of each mapped stratigraphic unit. Full details regarding local stratigraphy exposed along this valley by backhoe-trenching are given elsewhere[2,3].

Periods of slow or fast floodplain aggradation, stability and erosion during the past 11,000 yr are immediately recognisable on Fig. 1. One facet of river history made especially evident is that conditions of 'grade' or stability have prevailed for only limited periods of time during the Holocene. Instead: (1) a major aggradation occurred between 10,500 and 8,100 yr BP, coevally with loess deposition on local hilltops[2]; (2) following a brief erosional event between 8,100 and 7,500 yr BP, the river rapidly readjusted its grade; (3) floodplain stability prevailed from 7,500 to ~5,000 yr BP; (4) by 4,600 yr BP a major change in long-term stream regime had occurred; and (5) since this time, rapid aggradation has alternated with closely-spaced intervals of erosion. This last period, characterised by lack of long-term stability, continues to the present.

The complexity of this Holocene alluvial sequence is of special significance to workers who map river terraces on the basis of their relative elevations above river level. The lowest well defined terrace by the Pomme de Terre River is the 'T1' level, about 4 m above the modern floodplain (T0). However, a pronounced break in slope between this terrace level and T0 is visible at only a few locations in the valley, where fortuitous erosion has removed intervening fills at intermediate levels between T1b2 and T0 (Fig. 1). Given this situation, some alluvial terraces along other rivers may well signify primarily that portions of the local depositional record are missing.

Comparison of the Pomme de Terre's floodplain history with regional long-term climatic trends, as evidenced by pollen-derived vegetational history, suggests a correlation between the two. The 7,500–5,000 yr BP period of floodplain stability along this river occurred during the 8,700–5,000 yr BP 'Prairie Maximum' in Missouri[4]. This former plant geography is believed to indicate a climate characterised by less effective precipitation, because the Prairie/Deciduous Hardwood Forest boundary was located far to the east of its modern location. Following the return of more moist regional climates ~5,000 yr BP, long-term stream regime changed. Closely spaced episodes of stream erosion and deposition began, and have continued up to the present.

What is the controlling factor causing long-term floodplain stability or instability along this stream? The timing of mid-Holocene stability along the Pomme de Terre is similar to the time of stability concluded by Haynes for many western US streams: 7,100–5,700 yr BP (ref. 5). This tends to dismiss Prairie Maximum grassland vegetation itself as the primary cause of floodplain stability: no such vegetation has been inferred for the mid-Holocene in the now semi-arid western US stream basins. A better hypothesis is that stability in both Missouri and the western US was the direct result of greatly increased recurrence intervals for moderately sized floods, due to pronounced zonal upper atmospheric circulation patterns at this time[6,7].

Comparing the Pomme de Terre sequence with others in the northern mid-latitudes tests a corollary to this hypothesis: that climatic periods of very high meridionality in upper atmospheric circulation should be accompanied by periods of instability along streams[7]. Horizontal bars extending temporally to the oldest and youngest date from each Pomme de Terre depositional unit are shown in Fig. 1. Gaps between these bars are the time intervals bracketing fluvial erosion at this site. Following this same method, two other published alluvial sequences were plotted adjacent to the Missouri chronology on Fig. 2. Haynes[5] produced the western US chronology by compiling radiocarbon dates from lithostratigraphic units mapped over a large portion of the western US. He described the considerable dendrochronological and archaeological evidence in the western US for an erosional interval some time between 750 and 450 yr BP, although this event was not shown by the few radiocarbon dates then available for this period. Recent ^{14}C dating of alluvium in northern Arizona confirms regional erosion ~450 yr BP (W. Robinson, personal communication) and this event is therefore also indicated on Fig. 2 for comparison. The central European chronology is my compilation of results presented by others[8–11]. It is based partly on dates obtained by dendrochronological analysis of fossil tree stumps and logs found in alluvial deposits. Because such dates are in calendar and not radiocarbon years BP, every such tree-ring-based date from these studies was first converted into radiocarbon years BP using a standard calibration curve[12] before plotting on Fig. 2.

The three alluvial chronologies thus compared show four coincident or overlapping time intervals bracketing fluvial erosion (black bars on Fig. 2). Stream erosion at 5,000–4,900, 2,900–2,500, 1,600–1,500 and 400–500 radiocarbon yr BP is compatible with all three alluvial sequences.

Other recent alluvial chronological work supports the existence of very widespread Holocene erosional episodes at these times. In southwestern Wisconsin, Knox and his students have demonstrated regional stream erosion between 6,000 and 8,000 yr BP, before 4,400 yr BP, before 3,100 yr BP and

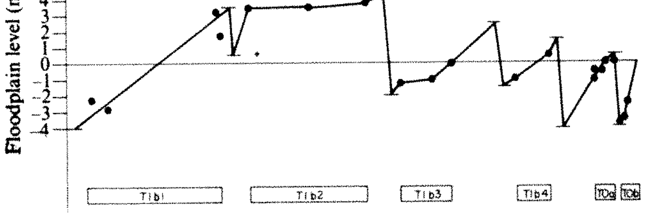

Fig. 1 Holocene level history of the Pomme de Terre River, southern Missouri, US. ●, Alluvial radiocarbon dates; + shows one of these dates that has poor reliability due to a large laboratory standard deviation. Short horizontal lines are undated stratigraphic tops or bottoms of each alluvial unit. Elevations are in metres above or below the modern floodplain, set at zero. Laboratory numbers of dates shown on this diagram are: ISGS-35, 48; SMU-429, 430, 431, 485, 500; UCR-819, 820, 823, 824; M-1900, 2281, 2333; GAK-1170, 1172; TX-1411, 1454, 1466; and A-867.

0028–0836/80/070655—02$01.00

between 1,800 and 1,225 yr BP (ref. 13). At the Koster site in southern Illinois, Butzer infers stream erosion at 5,000, 2,000 and 1,200 yr BP (ref. 14), although the latter two episodes are "fixed in relation to the regional archeological sequence" (personal communication). In Austria, along the Danube River, Fink's dates and cross-sections[15] support erosion between 8,500 and 7,000 yr BP, shortly before 4,200 yr BP, before 2,390 yr BP, shortly before 1,700 yr BP and between 560 and 400 yr BP. Finally, in Poland, Jersak dates an erosional unconformity in alluvial sediments between 8,620 and 6,160 yr BP[16], and Lindner presents a cross-section showing the basal portion of an alluvial fill dated at 1,850 and 2,060 yr BP (ref. 17).

Together, this is convincing evidence that sporadic episodes of widespread stream erosion have occurred during the past 5,000 yrs in the northern mid-latitudes. This result does not contradict dis-synchroneity of alluvial sequences at other times. Thus, stream erosion between 8,500 and 6,000 yr BP occurred at most localities mentioned above, but the data so far available are compatible with either: two closely spaced erosional intervals centering on 7,700 and 6,500 yr BP, and perhaps felt only locally, or one time-transgressive event between 8,000 and 6,500 yr BP, beginning earlier in eastern Europe and central North America, and later in central Europe and western North America.

The cause of the widespread stream erosion at the times shown in Fig. 2 is suggested by the timing of the Northern Hemisphere 'little ice ages'. These chronologies of mountain glacier advances have been assembled by Quaternary geologists working largely independently. However, their work shown in Fig. 2 demonstrates that Holocene glacial activity has been clustered around certain time intervals, even when the most divergent record (no. 6 in Fig. 2) is included. Widespread fluvial erosion seems to occur approximately at the beginning of little ice age climatic phases.

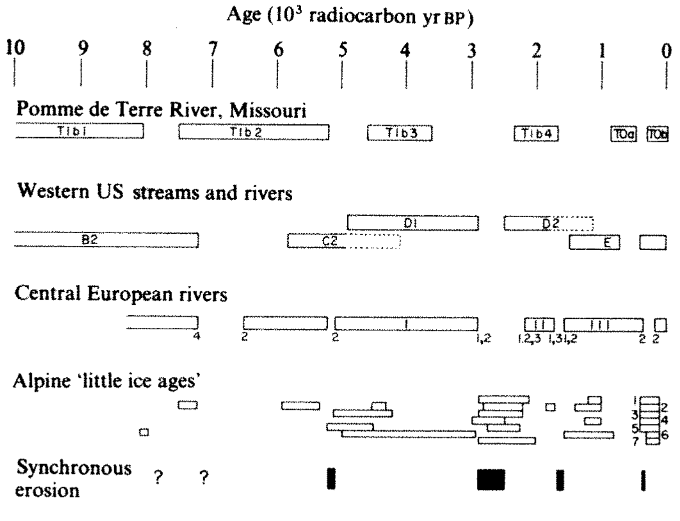

Fig. 2 Holocene alluvial and glacial chronologies compared. Key numbers 1–4 for 'Central European Rivers' refer to refs 8–11, respectively. Key numbers for 'Alpine Little Ice Ages' indicate the following references: 1, Alaska, ref. 21; 2, Swedish Lapland, ref. 21; 3, British Columbia and northern Washington, ref. 22; 4, Norway, ref. 23; 5, glaciations common to the eastern and western Alps, ref. 24; 6, Colorado Rocky Mountains, ref. 25; 7, Mexican volcanoes, ref. 26.

Other proxy palaeoclimatic indicators support climatic change occurring at these times, and help to clarify the nature of these changes. According to the California tree-ring results of LaMarche from both upper and lower treeline[18], the times of widespread glacial advances and stream erosion were characterised by rapidly decreasing land temperatures and increasing precipitation. Unfortunately, there are no such very long tree-ring climate series from the central US or Europe, and most pollen data from the central US are not sensitive enough to record short-lived climatic changes. However, "reconstructions of late-Holocene positions of treeline in Keewatin and Mackenzie, NWT, Canada, indicate that treeline was located south of its present position at about 2,900, 1,800 and 800 radiocarbon yr BP" and this is compatible with "increases in the strength of the meridional component of the large scale upper atmospheric circulation" at these times[7]. Moreover, Frenzel concludes that a variety of palaeoclimatic indicators from southwestern Europe also support greater meridionality at 5,200–4,400, 3,500–3,000, 1,700–1,200, and 800–600 yr BP, with shorter cooler and/or wetter phases ~2,700–2,500 yr BP, and within the past 600 yr[6]. Certainly it is hazardous to attempt detailed climatic comparisons over large areas on the basis of diverse palaeoclimatic indicators. Yet certain large scale changes have apparently left relatively unambiguous traces. If climatic change was the ultimate cause for recurring episodes of stream erosion during the past 5,000 yr, then the assembled palaeoclimatic evidence favours intensified meridionality in upper atmospheric circulation as the direct cause. This hypothesis was first advanced by Knox[7], on the basis of a statistical analysis of alluvial radiocarbon dates.

Because river channels are formed by floods with a recurrence interval of between 1 and 2 yr[19], channel widening or vertical channel incisement, therefore, occurs whenever floods of such recurrence intervals increase in size. During modern times, significant increases in meridional upper atmospheric circulation have been shown to result in such flooding over large areas[20]. Therefore, widespread episodes of Holocene stream erosion are to be expected if climatic regimes characterised by highly meridional circulation occurred in the past. Proxy palaeoclimatic records suggest that such regimes did occur, and at the correct times. Positive glacial mass balances in several mountain ranges resulted, even as increased flooding and discharge occurred along lowland streams. In contrast, one long interval of predominantly zonal flow was characterised by floodplain stability.

Age of volcanism and rifting in southwestern Ethiopia

A. Davidson

Geological Survey of Canada, Ottawa, Canada K1A OE4

D. C. Rex

University of Leeds, Leeds LS2 9JT, UK

It has been suggested that volcanism in the Ethiopian region of the Afro-Arabian Rift System has migrated with time, both laterally towards the present axial zone[1-3] and longitudinally southwards from the Red Sea[4,5]. Field data and K-Ar isotopic ages from southwestern Ethiopia, summarised below, indicate that volcanism in this area began earlier than previously suspected, and that Quaternary volcanism was not restricted to the axial zone. That major rifting in this region did not happen until the late Miocene[6,7] is corroborated.

The Afro-Arabian Rift System in southwestern Ethiopia is particularly wide and complex[8], embracing from east to west the southern termination of the Main Ethiopian Rift (Ganjuli graben[9,10]), the Stefanie Rift, and three northward-terminating branches (Usno, Omo and Kibish) of the Turkana (Lake Rudolf) Rift. Rugged terrain between the Ganjuli graben and the western edge of the Ethiopian Highland, 450 km north-west, exposes crystalline basement overlain unconformably by various Tertiary and Quaternary volcanic rocks[11,12] (Fig. 1).

The Tertiary volcanic rocks are broadly divisible into two categories, based on whether erupted before rifting or not. Among those in the pre-rift category, some relative age distinctions can be made based on local unconformities within flow successions or on the nature of the unconformity on crystalline basement. The oldest suite, referred to as the main sequence, overlies crystalline basement with a characteristic, thin, basal unit of red, indurated, residual grit. Continuity of this uniform grit, not faulted or eroded before covering by lava, coupled with lack of both organic remains and evidence of fluviatile origin, suggest that most of this region was a featureless, dry peneplain, probably at low elevation, at the inception of Tertiary volcanism. Younger flows, generally conformable on and thus difficult to separate from the main sequence in the central north-east part of the area, overstep the main sequence on to basement to the west, south-west and south, and all lack a basal, red grit. Phonolite flows and small intrusions respectively overlie and cut all earlier flows and comprise the youngest pre-rift igneous rocks.

In the post-rift category, flood basalt sheets lie with marked unconformity on tilted pre-rift flows and are channelled by rift-related topography. Quaternary volcanism not only occurred locally within the Stefanie and Turkana Rifts but also on adjacent highland blocks, notably in the north-west where it built a huge shield astride the Tertiary unconformity, far removed from the axial rift zone.

Conventional K-Ar isotopic ages were obtained by analytical procedures described by Briden *et al.*[13] for basalt samples collected throughout the area from the base of successions that lie on crystalline rocks. Ages for rhyolite within the main sequence and for two phonolite intrusions were also determined. Age data are given in Table 1; sample locations are plotted in Fig. 1. Of 12 samples from the base of the main sequence, five cluster at ~40 Myr, three from near the Sudan border are distinctly older at ~48 Myr, one (C774) is anomalously old, and three are significantly younger. Of the latter, K095 is judged anomalous because it lies several hundred metres below rhyolite (A515) dated at 32.7±1.3 Myr. Two periods of extensive younger basalt effusion are documented by clusters of ages at ~32 Myr (Gok and Makonnen basalts in the north-west, Fejej basalt east of Lake Turkana) and ~20 Myr (Teltele basalt in the south-east and Surma basalt near the Sudan border). Ages of C775, 23.1 Myr, and B425, 54.7 Myr, are unexplained anomalies at unconformities where other age data are consistent. Phonolite in the Stefanie Rift is dated at ~13 Myr. Basalt (4.2 Myr) in outliers east of Lake Turkana is much younger than the Fejej basalt which it oversteps.

The age data accord well with published ages from the same region. Early main sequence flows are of the age suggested for the pre-Oligocene Ashangi basalts of central Ethiopia[2,10]. Makonnen, Gok and Fejej basalts are similar in age to the Aiba basalts of central Ethiopia[1,2,15,16] and to early basalts in northern Kenya[17]. 35–37 Myr ages obtained from low in the main sequence near the south end of the Main Ethiopian Rift are midway between these two groups, and 31 Myr old flows occur higher in the same succession without an unconformity between them[9,10]. The much younger Teltele and Surma basalts have probable age equivalents in flows overlying Fejej basalt east of Lake Turkana[18], and in the middle part of the pre-rift succession in the lower Omo Valley[19]. Phonolite igneous activity is the same age as in adjacent Kenya[17,20]. The post-rift basalt north-east of Lake Turkana correlates closely in age with the Mursi basalt in the Omo Valley[7,19], and with the Harr basalt east of Lake Turkana (R. T. Watkins, personal communication).

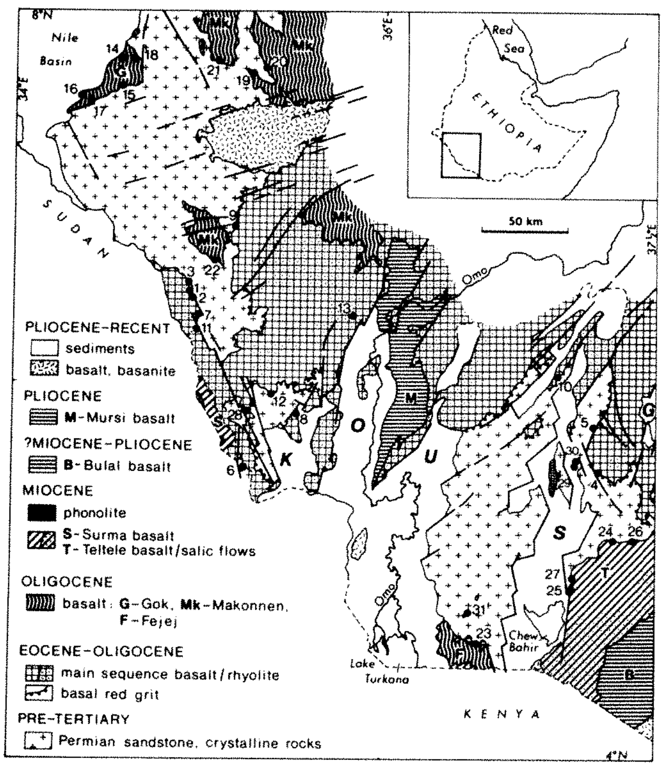

Fig. 1 Geology, southwestern Ethiopia, and location of dated samples. G, Ganjuli graben; S, Stefanie Rift; U, O and K, Usno, Omo and Kibish branches of Turkana Rift.

We conclude: (1) volcanism began as long ago as the middle Eocene and was widespread by the late Eocene in south-western Ethiopia. Early flows were deposited on a peneplain, likely at low elevation. Whether these flows were once continuous with the Ashangi basalts of central Ethiopia, or whether the two relate to separate broad centres of Eocene volcanism is not known. (2) Throughout the Oligocene, a broad arch developed, concave to the north-east, with uplift maxima in the north-west and south-east parts of the area. Oligocene and Miocene lavas covered older flows and overlapped on to basement, in part re-exposed, on top of and flanking the south and west sides of this arch. (3) Major rift structures did not form across this uplift until after Miocene (13–12 Myr) phonolite volcanism, although shallow proto-rifts may have existed somewhat earlier[21]. Rift topography was fully developed by the early Pliocene (5–4.5 Myr). (4) Correlation of Gok and Makkonen basalts, whose base elevations differ by 1.5 km, implies major faulting at the western edge of the Ethiopian Highland. (5) Quaternary volcanism was not restricted to the axial rift zone, but occurrences outside this zone are spatially related to new developing rifts or fracture zones. These discoveries in southwestern Ethiopia require that the pattern of migration of volcanism with time in the Ethiopian region of the Afro-Arabian Rift System be re-assessed.

Free calcium in *Xenopus* embryos measured with ion-selective microelectrodes

T. J. Rink & R. Y. Tsien

A. E. Warner*

Department of Anatomy and Embryology, University College London, Gower Street, London WC1, UK

A regulatory role for intracellular free calcium has been suggested in cell division[1] and intercellular communication via gap junctions[2,3]. Previous measurements of cytoplasmic free Ca^{2+} during cell division and uncoupling have been made with the Ca^{2+}-sensitive photoprotein aequorin[4,5]. We now report experiments using Ca^{2+}-sensitive microelectrodes to monitor free Ca^{2+} in the cells and intercellular fluid of early embryos of the amphibian *Xenopus laevis*. In addition to measuring basal levels, we have looked for changes in free Ca^{2+} during cell division and during electrical uncoupling of the normally coupled embryonic cells, induced by acidification of the intracellular medium[5–7].

Ca^{2+}-selective microelectrodes, tip size 1–2 μm, were made with a neutral ligand sensor based on that originally described by Oehme *et al.*[8]. The micropipettes were siliconised with tributylchlorosilane vapour at 200 °C. The sensor contained 2.4% tetraphenylphosphonium bis(1,3-diethyl-2-thiobarbiturate)trimethineoxonol in place of the 1% sodium tetraphenylborate commonly used in this type of electrode. Details of the fabrication, calibration and properties of these electrodes will be published elsewhere (R.Y.T. and T.J.R., in preparation). In the presence of 0.1 M KCl, the electrodes showed ideal (Nernstian) responses between *p*Ca 3 and *p*Ca 6 (1 mM to 1 μM free Ca^{2+}), 12–20 mV between *p*Ca 6 and 7, and 4–8 mV between *p*Ca 7 and 8. Interference from H^+ and Mg^{2+} was negligible. At *p*Ca 7 and 6, alterations in *p*H between 7.8 and 6.5 produced no detectable electrode response. Elevation of free Mg^{2+} from 0 to 5 mM or of Na^+ from 0 to 20 mM had less effect on the electrode potential than raising free Ca^{2+} from 0 to 0.1 μM. The free Na^+ in *Xenopus* embryonic cells is probably no more than 20 mM (ref. 9). High concentrations of CO_2 did not alter the electrode responses.

Basal measurements were made on embryos between the 2-cell and 64-cell stages. The mean value for cytoplasmic Ca^{2+} was *p*Ca 6.5 (0.32 μM) ± 0.12 (mean ± s.e.m.) from 12 reliable

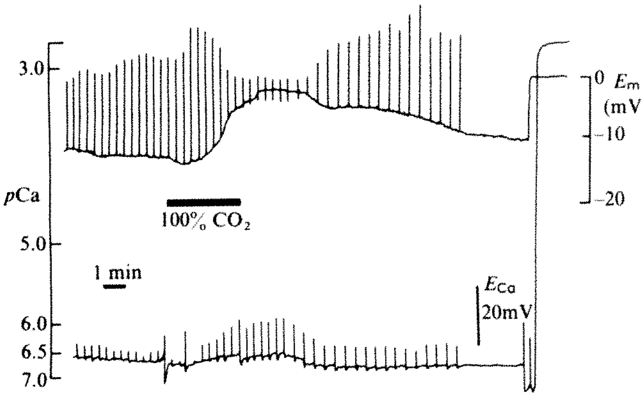

Fig. 1 Membrane potential, electrical coupling and intracellular free Ca^{2+} in a 16-cell *Xenopus* embryo during exposure to 100% CO_2. Three intracellular microelectrodes were used; one voltage recording electrode and one Ca^{2+}-sensitive electrode in one cell, and a third electrode in an adjacent cell which injected repetitive, rectangular current pulses (10 nA, 1 s duration). Upper trace gives the membrane potential, the lower trace the potential E_{Ca}, measured as the difference between the potentials recorded by the voltage and Ca^{2+}-sensitive electrodes. Electrotonic potentials produced by current injected into the adjacent cell are shown as upward deflections on the membrane potential record. The height of these deflections gives a simple indication of the degree of current spread from cell to cell. The changes in input and junctional resistances during CO_2 treatment have been documented[6,7]. The deflections on the lower trace reflect capacitative artefact which is picked up to a greater degree by the Ca^{2+} electrode because of its long electrical time constant. The frequency of the injected current pulses was reduced during the latter part of the trace to improve resolution of baseline E_{Ca}. The right-hand vertical axis shows the membrane potential. The left-hand vertical axis shows the *in vitro* calibration for this Ca^{2+} electrode. All *p*Ca calibrating solutions contained 0.1 M KCl. The required *p*Ca was set by 5 mM Ca and 10 mM ligand, nitrilotriacetic acid for *p*Ca 5.0, *N*-(2-hydroxyethyl)ethylenediamine-N,N',N'-triacetic acid (HEEDTA) for *p*Ca 6.0 and 6.5, and EGTA for *p*Ca 7.0. The solutions also contained 10 mM TAPS, HEPES, HEPES and MOPS respectively, and were titrated with KOH to the correct *p*H values (8.42, 7.70, 8.20 and 7.29) to give the desired *p*Ca using stability constants from ref. 18. The embryo was continuously superfused with a Holtfreter solution containing 60 mM NaCl, 1 mM KCl, 1.8 mM $CaCl_2$ and 2 mM ACES, *p*H 6.5. During the period marked by the bar, the superfusion solution was changed to bicarbonate-buffered Holtfreter solution (40 mM $NaHCO_3$ replacing 40 mM NaCl) bubbled with 100% CO_2. After 3 min of exposure to CO_2, the cell had depolarised and the voltage deflections had completely disappeared, only a biphasic capacitative artefact remaining on the trace. The lower, E_{Ca}, trace shows a small increase in intracellular Ca^{2+}. On return to the initial Holtfreter solution electrical coupling and E_{Ca} recovered. The current pulses were stopped, and first the voltage and then the Ca^{2+}-selective electrode were withdrawn. The recording was deliberately terminated before the membrane potential had reached its original level to recalibrate the Ca^{2+} electrode as soon as possible after the baseline *p*Ca level had been re-established.

impalements in 10 embryos from 7 different batches. The lowest Ca^{2+} levels in this series were *p*Ca 7.3 and 7.1. As most of the errors and artefacts in this type of experiment will lead to elevations in free Ca^{2+}, the value in undisturbed cells is likely to be in the region of 0.1 μM. This is in line with values for free Ca^{2+} obtained in a variety of other cells using all available techniques[10-12]. It contrasts with the ~7 mM total Ca^{2+} in these embryos[9]. Free Ca^{2+} in the intercellular fluid, which lies in the blastocoel cavity, came to 1.12 ± 0.04 mM (±s.e.m., $n = 9$).

No changes in free Ca^{2+} were detected during the cell cycle; in some cases the electrodes remained in one cell throughout two complete cleavages. Further evidence for the measured *p*Ca level and lack of transients comes from complementary experiments in which eggs were injected with calcium buffer solutions to try to set and maintain intracellular free Ca^{2+} levels (ref. 4 and below). Cells buffered to less than 10 nM Ca^{2+} did not divide, suggesting that the electrode measurements of ~0.1 μM Ca^{2+} in uninjected, dividing cells is not a gross overestimate. Cells buffered at around 0.1 μM calcium did divide, suggesting that transients above this level are not essential.

Two experimental procedures reported to block the flow of electrical current via gap junctions from one cell to another are elevation of intracellular free Ca^{2+} (refs 2, 3) and intracellular acidification with CO_2-rich external solutions[6,7,13]. It is known that raising intracellular Ca^{2+} can produce a fall in intracellular *p*H (*p*H_i)[14], and conversely in some preparations lowering *p*H_i may increase free Ca^{2+} (refs 5, 15). The question then arises whether Ca^{2+} and H^+ act independently on the gap junctions or whether one ion acts via the other. To try to examine this question directly, free Ca^{2+} levels were measured in 16- to 64-cell stage embryos during exposure to 100% CO_2. This level of CO_2 almost invariably uncouples cells in these embryos[6,7]. In a few experiments electrical coupling was monitored along with free Ca^{2+}; in others the depolarisation known to accompany the uncoupling was used to mark the effect of CO_2 on the cells. Figure 1 shows an experiment on a 16-cell embryo with an initial *p*Ca of 6.7. On exposure to 100% CO_2 (with almost constant external *p*H), the cell depolarised and current flow from cell to cell was abolished. The *p*Ca increased to about 6.45 (free Ca^{2+} elevation from 0.2 μM to 0.35 μM). After removal of the CO_2 these changes reversed. Similar small elevations of *p*Ca were seen in other experiments. In six trials the mean initial *p*Ca was 6.4 ± 0.13 (±s.e.m.) and during exposure to 100% CO_2 the mean peak level of *p*Ca was 6.19 ± 0.1 (0.63 μM). Thus lowering *p*H_i from about 7.8 to 6.5 (ref. 7) modestly raises free Ca^{2+} to less than 1 μM. The measurement of these small elevations in free Ca^{2+} relies on the virtual insensitivity at *p*Ca 6–7 of the electrodes to *p*H changes over the experimental range, a technical advantage not shared by other techniques in use[5,16,17]. The source of the Ca^{2+} transient has yet to be established. Some Ca^{2+} could enter the cells across the plasma membrane from the

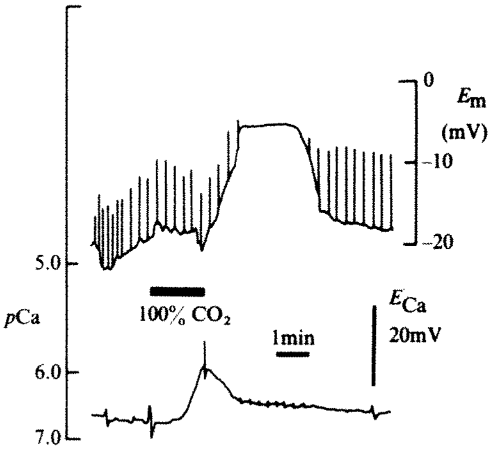

Fig. 2 Effect of 100% CO_2 on electrical coupling, membrane potential and E_{Ca} in one cell of an embryo at the 32-cell stage which was preinjected with CaEGTA. All experimental conditions were as in Fig. 1. A small amount, about 5% of the cell volume, of 200 mM CaEGTA solution containing some fast green FCF stain was injected into one half at the 2-cell stage. The injected half was recognised at later stages of development by the green stain and by the changes in pigment distribution which occurred during CO_2 treatment only in the injected half. Before withdrawing the electrode this embryo was again challenged with 100% CO_2 (not illustrated). This produced a slightly smaller and less prompt rise in *p*Ca, but the cells did not uncouple. The absence of uncoupling may have been because the embryo suffered cumulative damage as a result of simultaneously raising Ca_i^{2+} and H_i^+. Normal embryos (not injected with CaEGTA buffer) uncouple repetitively in response to successive changes with 100% CO_2 (ref. 7).

blastocoel fluid; equally acidification may release Ca^{2+} from intracellular binding sites. It is even possible that CO_2 might release part of the bound Na^+ of these cells[9], which might then contribute to the electrode response. If so, then the true Ca^{2+} transient would be even smaller than the figures quoted above.

Could the CO_2 have induced larger elevations of Ca^{2+} that escaped detection? To check that large transients could be seen, free Ca^{2+} levels were measured in embryos which had been injected with 200 mM CaEGTA (1:1 Ca to EGTA) to a final concentration of 5–10 mM. The injection was made into one cell of a two-cell embryo, which was then left to cleave to the 32- or 64-cell stage. At the normal pH_i of 7.8, almost all the injected Ca^{2+} would stay complexed to the EGTA as the effective dissociation constant was 10 nM (ref. 18). The CaEGTA then would have very little buffering power and could hardly change the free Ca^{2+} inside the cell. On acidification to, say, pH 6.5, the effective dissociation constant would rise to 4 μM, high enough for much of the Ca^{2+} to be unloaded and for the EGTA now to contribute significantly to the total calcium buffering inside the cell. The free Ca^{2+} should go to some value near 4 μM (pCa 5.4) depending on the relative buffer capacities of the cytoplasm and the injected EGTA. Figure 2 shows an experiment of this type. On the application of 100% CO_2 there was a marked, abrupt increase in free Ca^{2+} from pCa 6.6 to 5.9 (0.25 to 1.25 μM). In seven such trials the mean initial and peak pCa values were 6.28 ± 0.16 and 5.76 ± 0.06. This latter value is reasonably close to the pCa 5.4 effective dissociation constant of the EGTA, considering that the intracellular Ca^{2+} buffering is not quantitated and that the change in pH_i is somewhat variable[7]. Clearly the electrodes are able to record large, experimentally induced elevations of free Ca^{2+}. As shown in Fig. 2 the application of CO_2 depolarised and uncoupled the cells; the Ca^{2+} transient was ending as the uncoupling began.

It seems, then, that 100% CO_2 produces elevations of free Ca^{2+} well below the ~50-μM level[2,19] considered to be necessary to abolish current flow from cell to cell. Again one could ask if CO_2 might have caused Ca^{2+} increases localised in every experiment far from the tip of the Ca^{2+} electrode. Two lines of evidence argue against such a possibility. First, Rose and Rick[5] have examined the effect of CO_2 on the luminescence of aequorin microinjected into *Chironomus* gland cells. In the 40% of cells which showed an increased glow, that increase was diffusely distributed. Second, we have injected *Xenopus* embryos with a new Ca^{2+} buffer, 1,2-di(*o*-aminophenoxy)ethane-*N,N,N′-N′*-tetraacetic acid[20], whose affinity for Ca^{2+} (log stability constant = 6.97) is practically independent of pH and Mg^{2+} in the physiological range. The final concentrations of ~10 mM buffer half-saturated with Ca^{2+} should have clamped the intracellular calcium near 0.1 μM. Of 45 such embryos, 64% continued to cleave, although often at a slower than normal rate. In 4 out of 5 injected embryos, the cells uncoupled when challenged with 60% or 100% CO_2. These experiments suggest that *Xenopus* embryos can still be uncoupled when Ca^{2+} transients are greatly damped.

Thus, our results show the levels of free Ca^{2+} in cells of the early amphibian embryo to be in the region of 0.1 μM. They suggest that cell division is not accompanied by transient changes in free Ca^{2+}. A minimum level of Ca^{2+} seems to be necessary for cell division to occur[4], but Ca^{2+} does not have a regulatory role in these cells. The results also support the view that CO_2-induced uncoupling of cells in this preparation is not mediated by alterations in free Ca^{2+} levels. However, the relative importance of Ca^{2+} and H^+ in the control of gap junction permeability may vary from tissue to tissue[21].

We thank Dr L. Turin for helpful discussion and D. Murphy for technical assistance. This work was supported by grants from the SRC and MRC.

Host gene influences sensitivity to interferon action selectively for influenza virus

O. Haller, H. Arnheiter, J. Lindenmann & I. Gresser

Several examples of genetically determined resistance to different viruses have been studied in mice[1]. Inborn resistance due to the allele *Mx* in A2G mice may be characterised as follows: resistance is specific for members of the orthomyxo family (influenza virus)[2]; it is expressed in different organs and cells[2–6]; and it is independent of a functioning immune system[3,4,7]. The only means of rendering resistant mice fully susceptible to influenza virus has been treatment with potent anti-interferon serum[8], indicating that interferon is important in resistance. Interferon is generally thought to inhibit the multiplication of all animal viruses relatively indiscriminately. Therefore, it had seemed unlikely that interferon was involved in this resistance, as A2G mice were selectively resistant to influenza virus albeit as sensitive as control mice to several other viruses[4]. There are, however, examples in which the genetic control of the production of interferon or the sensitivity to interferon action is expressed selectively for a given virus. Thus, De Maeyer and coworkers have shown that four different *If* loci control the amount of circulating interferon produced after injection of mice with Newcastle disease virus (NDV)[9], mouse mammary tumour virus[10], or Sendai virus (personal communication). Hanson *et al.*[11] found that cultures of cells from C3H RV mice, resistant to Arbo B virus infection, were much more susceptible to the inhibitory effect of interferon when tested with Arbo B viruses than cultures taken from susceptible C3H mice. We present here results, showing that cultures of macrophages from mice resistant to orthomyxoviruses (*Mx* positive) can be protected by much smaller amounts of interferon than are necessary to protect cultures from susceptible mice when these cultures are infected with influenza virus; whereas no difference in sensitivity to interferon is observed when cultures are infected with vesicular stomatitis virus (VSV) or encephalomyocarditis virus (EMC). We believe that these results showing a genetic control of sensitivity to interferon action specific for a given virus are related to the *in vivo* resistance of A2G mice to influenza virus. If applicable to man, these results may also be of importance in understanding individual variations in sensitivity to viral infections.

0028-0836/80/070660—03$01.00

Table 1 Viral susceptibility of cultured macrophages

Macrophage		Titre of virus ($\log_{10}$ TCID$_{50}$ per ml)		
Origin	Genotype	M-TUR	EMC	VSV
CBA/J	(+/+)	8.3	7.8	8.5
A/J	(+/+)	7.8	ND	9.0
A2G	(Mx/Mx)	7.8	7.8	8.8
(A2GxA/J)F$_1$	(Mx/+)	8.3	ND	ND

A/J and CBA/J mice were from G. L. Bomholtgård. Inbred A2G mice, homozygous for the resistance allele Mx^2 and heterozygous (A2G × A/J)F$_1$ hybrids were bred locally. Macrophage cultures were prepared as described previously[6,8]. Briefly, peritoneal macrophages from 8- to 12-week-old mice stimulated 3 days previously by intraperitoneal (i.p.) injection of 2 ml of thioglycollate medium were collected. 1.5×10^6 viable cells in 1.0 ml of RPMI 1640 medium were plated into 16-mm wells of 24-well tissue culture cluster plates. After frequent washings to remove non-adherent cells, macrophages were incubated for 4 days in serum-free medium. Thereafter, RPMI 1640 medium supplemented with 10% heat-inactivated fetal calf serum was added and adherent cells were kept in culture for a total of 21 days. Macrophage cultures were then washed and 0.5 ml of serial 10-fold viral dilutions in serum-free culture medium were added to quadruplicate wells. Cytopathic effects for the following three viruses were assessed 72 h after infection: *M-TUR*, an avian influenza A virus strain derived from A/Turkey/England/63 (Hav$_1$, Nav$_3$)[17] adapted to grow in mouse peritoneal macrophages *in vitro*[6]. Stock allantoic fluid had a haemagglutination titre of 1:640 and $10^{8.7}$ mean tissue culture infective doses (TCID$_{50}$) per ml when assayed on primary chick embryo fibroblast (CEF) cultures. *VSV*, serotype Indiana was grown and stored as previously described[15]. VSV stock allantoic fluid had a titre of $10^{8.7}$ TCID$_{50}$ per ml on L$_{929}$ cells. *EMC* virus[18] was propagated in monolayer cultures of L$_{929}$ cells and was adapted to grow in mouse macrophages by five consecutive passages in the murine macrophage monocytic tumour cell line J-774 (ref. 19) followed by two passages in peritoneal macrophages from CBA/J mice cultured for 3 weeks. Virus stocks consisted of cell free medium from 24-h cultures of J-774 cells and had a titre of $10^{8.5}$ TCID$_{50}$ per ml for L$_{929}$ cells. ND, not determined.

Macrophages collected from the peritoneal cavity of A2G mice are resistant to influenza virus when first placed in culture[6], but become susceptible with time[8]. We therefore cultivated peritoneal macrophages for 3–4 weeks, at which time they were highly susceptible to the three test viruses used, macrophage-adapted orthomyxovirus strain (M-TUR), a rhabdovirus (VSV) or a picornavirus (EMC) (Table 1). At 3 to 4 weeks, cultures of macrophages were incubated with graded doses of mouse interferon for 18 h before viral challenge. Two preparations of mouse interferon induced by NDV in mouse C-243 cells were used: (1) partially purified to 1×10^7 reference units per mg protein[12]; (2) highly purified by sequential chromatography on sheep anti-interferon antibody[13] and CM-sepharose[14] columns to 5×10^8 reference units per mg protein (a gift from Dr M. Aguet).

Figure 1 illustrates the effects of 40 and 400 reference units of partially purified interferon on the multiplication of influenza virus M-TUR in macrophages from CBA/J (susceptible) and A2G (resistant) mice. At high (Fig. 1 *a*, *b*) and low (Fig. 1 *c*, *d*) multiplicities of infection, both interferon doses markedly inhibited virus replication in A2G mouse macrophage cultures (Fig. 1 *b*, *d*), whereas even 400 interferon units exerted only a slight inhibition or delay of viral multiplication in CBA/J macrophage cultures (Fig. 1*a*, *c*).

Figure 2 shows the effect of different amounts of highly purified interferon on the multiplication of M-TUR virus and EMC virus in cultures of macrophages from (A2G × A/J)F$_1$ mice (heterozygous for the gene *Mx* and thus genetically resistant to influenza virus but susceptible to EMC virus[2]) and from A/J mice (susceptible to both viruses). The inhibitory effect of interferon on the multiplication of EMC virus was similar in cultures of macrophages from these two strains of mice. In contrast, a marked difference was observed in the degree of inhibition by interferon of the multiplication of M-TUR virus in

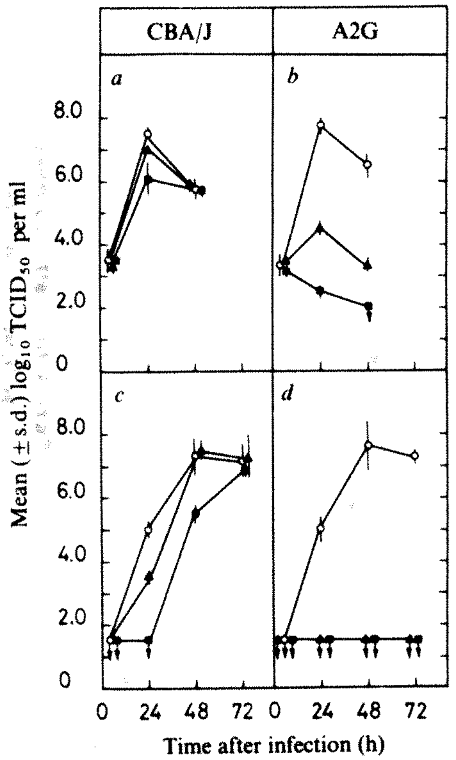

Fig. 1 Inhibition by interferon of multiplication of M-TUR virus in cultures of macrophages from susceptible CBA/J mice (*a*, *c*) or resistant A2G mice (*b*, *d*). Peritoneal macrophages cultivated for 3 weeks in culture were incubated for 18 h with 40 (▲) or 400 (■) reference units per ml of partially purified mouse interferon. Interferon pretreated and untreated cells (○) were then washed and infected with M-TUR virus at multiplicities of either 5 (*a*, *b*) or 0.005 (*c*, *d*). After incubation for 60 min at 37 °C the virus inoculum was removed by repeated washings. Cell-free medium from individual cultures was assayed for infectivity on CEF cultures at the times indicated. Each point indicates the mean TCID$_{50}$ from three cultures with standard deviation.

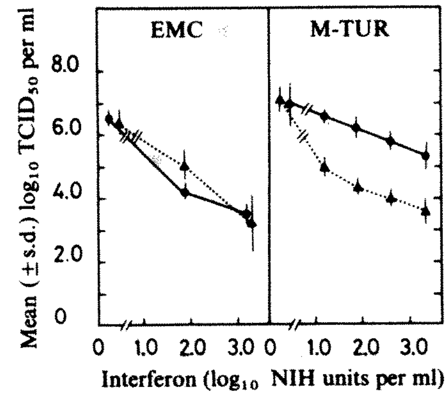

Fig. 2 Effects of highly purified interferon on multiplication of EMC and M-TUR virus in macrophages from resistant or susceptible mice. Peritoneal macrophages from resistant (A2G × A/J)F$_1$ mice (Mx/+), (▲ ··· ▲), and from susceptible A/J mice, (+/+), (●——●), were cultured for 3 weeks and incubated for 18 h with various doses of highly purified interferon. Thereafter, cultures were washed and infected at a multiplicity of 5 with either M-TUR or EMC virus. After an incubation period of 60 min at 37 °C the virus inoculum was removed by repeated washings. The viral titre of cell-free medium from four individual cultures per interferon dilution was determined 18 h after viral infection (at the time of peak virus production in control cultures). EMC virus was titred in monolayer cultures of L$_{929}$ cells and M-TUR virus in CEF. Mean TCID$_{50}$ values and standard deviations are indicated. The differences in yields of M-TUR virus between interferon-treated +/+ and Mx/+ macrophage cultures were statistically significant ($P < 0.005$ for all interferon doses used).

Fig. 3 Effect of interferon on the multiplication of M-TUR and VSV in macrophage cultures from backcross mice segregating for the allele *Mx*. (A2G×C57BL/6J)F$_1$ were backcrossed with C57BL/6J mice. The offspring were characterised as carriers (Mx/+) or noncarriers (+/+) of the allele *Mx* as described[6]. After 3 weeks in culture, peritoneal macrophages obtained from individual Mx/+ or +/+ backcross mice were incubated for 18 h with 20 (*a*) or 40 (*b*) reference units of partially purified mouse interferon. Cells were then washed and infected with either VSV (*a*) or M-TUR (*b*) at a multiplicity of 5. After incubation for 90 min at 37° C the virus inoculum was removed by repeated washings. Cell-free medium from individual cultures was titrated on CEF monolayers at the times after infection indicated. Titres represent mean values from three macrophage cultures of either resistant (Mx/+) or susceptible (+/+) genotype. ○, (+/+) Untreated; ●, (+/+) interferon-treated; △, (Mx/+) untreated; ▲, (Mx/+) interferon-treated.

macrophage cultures from these mice. Thus in A/J cells, 2,000 reference units of interferon resulted in only a 50-fold reduction in the yield of M-TUR virus, whereas the same amount of interferon reduced M-TUR virus yield by 4,000-fold in (A2G×A/J)F$_1$ cells.

In backcrosses segregating for the two alleles at the *Mx* locus, the susceptibility (+/+) or resistance (Mx/+) to orthomyxoviruses of individual mice can be determined by typing peritoneal macrophages[6]. Interferon had a similar and profound inhibitory effect on the multiplication of VSV in both Mx/+ and +/+ cells (Fig. 3*a*) (Mx/+ and +/+ mice are equally susceptible to VSV)[15]. In contrast, interferon slightly delayed multiplication of M-TUR virus in +/+ cells, but markedly inhibited its multiplication in Mx/+ cells (Fig. 3*b*).

We have not yet determined which step in influenza virus replication is affected in interferon treated *Mx*-bearing cells. Our preliminary results indicate that neither virus adsorption nor virus penetration are involved but that viral protein synthesis seems to be blocked at an early stage (M. Horisberger *et al.*, in preparation).

Most laboratory strains of mice do not carry the *Mx* gene, and thus support influenza virus multiplication despite exposure to relatively large amounts of interferon. However, there are indications that resistance of wild mouse populations to orthomyxoviruses is widespread (O.H., unpublished). We do not know whether this resistance is also interferon mediated (as in our A2G mice) but it is of interest that interferon also seems to be involved in mouse resistance to flaviviruses[11], and that wild mice are also frequently found to be resistant to these viruses[16]. The phenomenon of genetic resistance to viral infections mediated by interferon may therefore be more general than has heretofore been supposed. It is an interesting example of cooperation between a nonspecific extrinsic factor (interferon) with an intrinsic element (the resistance gene) resulting in a degree of antiviral specificity. Thus, the resistance gene can be envisaged either as modulating the antiviral state induced by interferon or as coding for an antiviral mechanism activated by interferon. Alternatively, it might be speculated that the seemingly nonspecific antiviral state generally observed in interferon-treated cells would be composed of a multitude of specific antiviral mechanisms each of which might be coded for by a unique resistance gene of the host cell. Allelism at such resistance loci would then account for various degrees of protection induced by interferon.

Histamine has been implicated in the pathogenesis of gastroduodenal ulcers[1,2]. Since mast cells contain a considerable amount of histamine as well as heparin and other biologically active substances[3], it seems reasonable to speculate that they are involved in this process[4,5]. In fact, development of gastroduodenal ulcers was reported in dogs with mastocytoma[6], and an increase in mast-cell number was described in the vicinity of human gastroduodenal ulcers[7,8]. Y.K. *et al.*[9] have recently found that the number of mast cells in a unit length of the skin of *W*/*W*^{v} mutant mice is less than 1% of the value for the congeneic +/+ mice and that no mast cells are detected in the intestinal canal of *W*/*W*^{v} mice. Therefore, this mutant mouse was used to investigate the role of mast cells in the induction of gastroduodenal ulcers. As a preliminary experiment, we examined the stomach and duodenum of *W*/*W*^{v} mice without any treatments. Unexpectedly, we found the spontaneous development of perforating stomach ulcers in *W*/*W*^{v} mice, suggesting that mast cells do not necessarily have aggravating effects on the production of stomach ulcers.

Table 1 Incidence of stomach ulcers in WBB6F$_1$ mice of different genotype, sex and age

		Incidence of ulcers in each age (no. (%))	
		1–2 months	2–6 months
W/W^v	Male	9/18 (50)	11/24 (46)
W/W^v	Female	21/28 (75)	4/16 (25)
$W/+$	Male and female	0/19 (0)	0/22 (0)
$W^v/+$	Male and female	0/18 (0)	0/20 (0)
$+/+$	Male and female	0/23 (0)	0/21 (0)

Mice of WBB6F$_1$(WB $-$ $W/+$ $\times$ C57BL/6 $-$ $W^v/+$)$-$(W/W^v, $W/+$, $W^v/+$, $+/+$) were used. WBB6F$_1$ mice were raised in our laboratory using parental stocks originally obtained from the Jackson Laboratory, Bar Harbor. The *W* genotype of all animals was inferred from the pattern of white spots and dilution of coat colour[10]. In addition to mast-cell depletion, the mice of W/W^v genotype show severe macrocytic anaemia, sterility and depletion of hair pigment[10]. Mice were kept in conventional animal facilities with *ad libitum* access to Oriental Lab Chow (Oriental Yeast Co.) and tapwater.

At an age of 1 to 6 months, W/W^v mutant mice and their littermates were killed; the abdominal wall was opened; deformity of pyloric region and adhesion between pylorus and adjacent organs were inspected. The stomach and duodenum were removed as a whole; the stomach was split along the greater curvature. After macroscopic examination, the stomach and duodenum were fixed in 10% buffered formalin (*p*H 7.2). Ordinary paraffin sections (5 μm thick) were made, and stained with haematoxylin and eosin to confirm diagnosis, or with toluidine blue to determine the number of mast cells, or with the periodic acid Schiff reaction to count the number of mucous cells. In most cases, subserial sections were made to determine the size of the ulcer when found. The diameter of the ulcer was measured in the largest cross-section of the ulcer using an occular micrometer attached to an eyepiece of the microscope.

Gastric secretions were collected for 4 h by the method described by Shay *et al.*[11]. The volume of secretion was measured, the acid concentration was titrated with 0.1 M NaOH, and the acid output was calculated. Pepsin concentration was determined according to the method reported by Anson and Mirsky[12]. Histamine was separated by column chromatography after dansylation from various parts of the stomach and its concentration was determined with the fluorimeter[13]. Distribution of enterochromaffin-like cells was examined with histofluorescence technique[14] with or without prior injection of L-dopa (100 mg per kg body weight) (ref. 15).

In about a half of the untreated W/W^v mice, chronic ulceration was found in the prepyloric region of the stomach. The incidence of ulcers was not affected by age in males, but was higher in young females (1–2 months) than in older ones (2–6 months) (Table 1). The size range of the ulcers was 0.6–4.5 mm and the median size was 2.2 mm. In some cases, the lesion was so wide that it occupied the whole prepyloric region, but it did not extend into the fundic part even in such cases. The ulcer frequently perforated, and adhesion of the pyloric region to the liver and pancreas was observed. Histologically, the ulcer crater contained necrotic debris and was sharply demarcated and infiltrated by inflamatory cells. The muscular layers were interrupted by granulation tissue and fibrous connective tissue (Fig. 1). When the section was stained with toluidine blue, no mast cells were detected either in the vicinity of the ulcer or in other parts of the stomach and duodenum. In contrast with the high incidence of ulceration in mast-cell depleted W/W^v mice, no ulcerative lesions were detected in the stomach and duodenum of $W/+$, $W^v/+$, and $+/+$ littermates which have a considerable number of mast cells in the stomach (Table 1).

Table 2 Number of various types of cells in the gastric mucosa of WBB6F$_1$-W/W^v and the congeneic $+/+$ mice

Cell type	No. of cells per gland (mean ± s.e.) W/W^v with ulcer	W/W^v without ulcer	$+/+$
Parietal cell	20 ± 3 (10)	18 ± 1 (15)	17 ± 2 (12)
Chief cell	15 ± 4 (10)	15 ± 2 (15)	12 ± 1 (12)
Surface mucous cell	23 ± 2 (10)	21 ± 1 (15)	21 ± 1 (12)
Neck mucous cell	7 ± 1 (10)	6 ± 1 (15)	7 ± 1 (12)
Pyloric mucous cell		33 ± 2 (7)	33 ± 1 (10)

Number of mice is shown in parentheses.

Table 3 Mast-cell number and histamine concentration in various parts of the stomach of WBB6F$_1$-W/W^v and the congeneic $+/+$ mice

Part of stomach	No. of mast cells*† (per cm of section) W/W^v	$+/+$	Histamine concentration* (nmol per g of wet tissue) W/W^v	$+/+$
Forestomach	0 (9)	172 ± 16 (11)	0.6 ± 0.4 (4)	78 ± 16 (4)

beneath muscularis mucosae	0 (9)	37 ± 7 (11)		21 ± 2 (4)

* Mean ± s.e., number of mice is shown in parentheses.

† See ref. 9 for the method used to determine the number of mast cells.

Since peptic ulcers are thought to occur as a consequence of an imbalance between the factors stimulating acid secretion and the factors protecting the gastric mucosa from acid/peptic digestion[16], the numbers of parietal cells, chief cells and mucous cells were counted in the stomachs of the $+/+$ mice and those of W/W^v mice with or without stomach ulcers. As shown in Table 2, the numbers of parietal cells, chief cells and mucous cells in the $+/+$ mice did not differ significantly from the values observed in W/W^v mice with or without the ulcers. Moreover, when the gastric juice was examined, there was no difference in the rates of acid and pepsinogen secretion between the $+/+$ and W/W^v mice.

As the normal acidity was observed in the stomach of mast-cell depleted W/W^v mice and as histamine is known to be a stimulator of acid secretion[16], the concentration of histamine was evaluated in the stomach of W/W^v and congeneic $+/+$ mice. The number of mast cells was counted in various parts of the stomach to compare with the concentration of histamine. Since the concentration of histamine in the forestomach of the

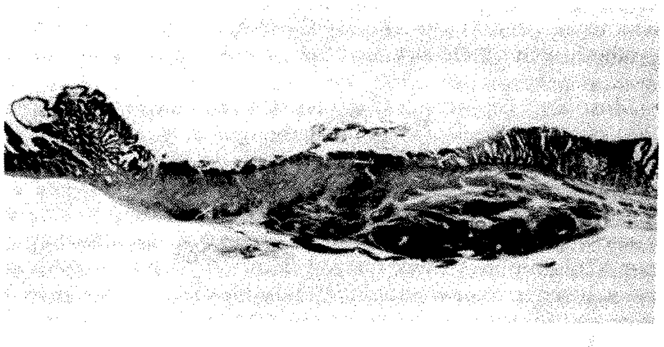

Fig. 1 Histological section of a chronic ulcer localised in the prepyloric region of the stomach of the untreated WBB6F$_1$-W/W^v mice (stained with haematoxylin and eosin).

W/W^v mice was less than 1% of the value of the +/+ mice, the histamine content seemed to be proportional to the number of mast cells in the forestomach (Table 3). In contrast, a considerable amount of histamine was detected in the glandular stomach of mast-cell depleted W/W^v mice (Table 3), suggesting the presence of histamine in certain types of epithelial cells located in the glandular stomach of the W/W^v mice. Examination with the fluorescence microscope revealed that the distribution and number of enterochromaffin-like cells in the fundic mucosa of the W/W^v mice were not significantly different from those observed in the congeneic +/+ mice. The prior injection of L-dopa increased the number of fluorescent cells in both W/W^v and +/+ mice.

The present results showed that the stomach ulcer developed spontaneously in mast-cell depleted W/W^v mice and that the glandular stomach of W/W^v mice contained a considerable amount of histamine in spite of its lack of mast cells. Since the number of enterochromaffin-like cells in the fundic mucosa of the W/W^v mice was not different from the value observed in the +/+ mice, histamine detected in the glandular stomach of the W/W^v mice appears to originate from certain types of enterochromaffin-like cells as demonstrated by Håkanson *et al.*[17]. Therefore, there are possibilities that histamine derived from enterochromaffin-like cells may have an essential role in the pathogenesis of gastroduodenal ulcers as postulated by Guth and Code[1] and Lees *et al.*[18] and that mast cells themselves might have inhibiting rather than aggravating effects on the production of ulcers.

The histological features of the ulcers found in the W/W^v mice are very similar to the chronic human ulcers[16]. Although production of acute ulcers in the fundic mucosa of rats by stress[19] and spontaneous development of duodenal ulcers in NZB mice[20] were previously reported, development of chronic ulcers in the prepyloric region is rare in untreated rodents. Therefore, the ulcer in the W/W^v mice may be a useful model of the human disease.

We thank Drs K. J. Mori, M. Seki, T. Watanabe and K. Matsumoto for valuable discussions. This work was supported in part by the Japanese Ministry of Education, Science and Culture.

Two distinct factors are required for induction of T-cell growth

Eva-Lotta Larsson*, Norman N. Iscove† & Antonio Coutinho*

* Department of Immunology, University of Umeå, Umeå, Sweden
† Basel Institute for Immunology, Basel, Switzerland

The molecular and cellular basis of T-lymphocyte activation remains a central question in immunology. The growth of already proliferating T cells is known to depend on T-cell growth factor (TCGF), a physiological mitogen[1]. Noncycling T lymphocytes, however, are not sensitive to TCGF[2]. They require a short contact with mitogenic lectins, such as concanavalin A (Con A)[3] or leukoagglutinin[4] to bind and respond to TCGF, and will thereafter maintain exponential growth for long periods provided that TCGF is not limiting[5]. While the induction of TCGF reactivity results from the direct contact of Con A with resting T cells[3], the lectin-dependent production of TCGF is known to involve two cell types, both present in mouse spleen[1,3,6,7]. One consists of I-A-negative cells, most of which are Thy-1-positive T lymphocytes[1,3], and the other consists of I-A-positive, immunoglobulin-negative, Thy-1-negative cells, most of which are macrophages[1,3]. The nature of the respective contributions of the two cell types, and in particular the cellular origin of TCGF, has not yet been established. We have now established the I-A-negative population as the source of TCGF and show here that macrophages are required to supply a 20,000-molecular weight factor, chemically and functionally distinct from TCGF, which supports the production of TCGF by the I-A-negative cells.

TCGF was recovered in conditioned medium from Con A stimulated mouse spleen cell cultures[5], and assayed by its capacity to maintain proliferation of T-cell blasts[1,8]. These were derived from spleen cell cultures initially stimulated by Con A and subsequently passaged in CM for periods of 3 weeks or more. Where indicated, a cloned TCGF-dependent cell line of specific cytotoxic T lymphocytes was also used[9]. When TCGF from Con A conditioned medium was partially purified by isoelectric focusing and then fractionated on Sephadex, TCGF activity was detected in fractions corresponding to an apparent molecular weight (MW) near 35,000 (Fig. 1). Identical activity profiles were obtained for fractions tested on the two types of T-cell blasts and on resting I-A-negative T cells after a 4-h sensitising pulse of Con A. The active fractions were pooled and used as a source of partially purified TCGF in subsequent experiments.

The proliferative responses of T cells to Con A were then examined in spleen cell populations depleted of I-A-positive cells. As previously found[1,3,7], Con A alone failed to induce proliferation (Table 1). We therefore tested medium conditioned by macrophages for its capacity to replace the I-A-positive cell requirement. The results shown in Table 1 were obtained with a partially purified preparation of medium conditioned by WEHI-3 cells. These are continuously growing cells of BALB/c origin with functional markers characteristic of macrophages[10]. This material supported a strong proliferative response in the presence of Con A, but it was inactive alone. In these culture conditions, partially purified TCGF seemed to exert a similar action, supporting a response in the presence, but not the absence, of Con A. The combination of TCGF and WEHI-3 activity, however, was inactive in the absence of Con A, demonstrating that the WEHI-3 activity cannot replace Con A in its role of sensitising T cells to TCGF.

Although the WEHI-3-derived activity and TCGF behaved similarly in cultures of resting, I-A-negative cells, their distinct functional properties were apparent in cultures of already proliferating, TCGF-dependent T-cell blasts (Table 1). In such cultures, only TCGF was able to sustain proliferation. WEHI-3 activity had no inhibitory effect in combination with TCGF.

0028-0836/80/070664—03$01.00

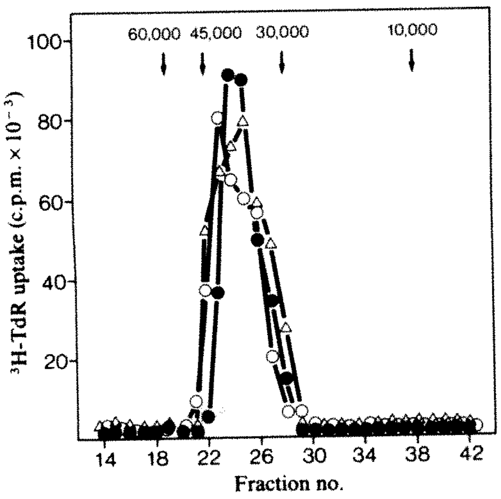

Fig. 1 Growth requirement of T-cell blasts and Con A pulsed purified T cells. Conditioned medium (CM) was obtained by incubating unseparated mouse spleen cells (5×10^6 per ml) for 24 h in the presence of concanavalin A (Con A) (5 μg ml^{-1}) (Pharmacia) in RPMI-1640 medium containing neomycin (50 μg ml^{-1}), HEPES (10 mM), 2-mercaptoethanol (5×10^{-5} M) and 1% fetal calf serum (GIBCO, batch U18710.11). CM (500 ml) was concentrated by dialysis against polyethylene glycol (MW 20,000, Serva), dialysed against buffered saline solution (BSS) and filter-sterilised (0.45 μM). Preparative flat-bed isoelectric-focusing (LKB) in a *p*H gradient from 3.0 to 10.5 was carried out over 24 h at constant power in Ultradex gel (LKB)[20]. Fractions were collected, eluted from small columns, dialysed against BSS, and tested for TCGF activity on T-cell blasts. The TCGF-containing fractions (*p*H 6.0–7.0) were pooled, lyophilised, dissolved in the running buffer, applied to a calibrated Sephadex G-75 superfine column (1.6 × 90 cm), and eluted with 4 mM HEPES containing 0.16 M NaCl and 10 μg ml^{-1} of polyethylene glycol (MW 6,000), *p*H 7.3. Fractions were tested for TCGF activity on Con A-derived T-cell blasts (5×10^4 per ml) (●), a cloned anti-HY (H-2^b) killer cell line[14] (5×10^4 per ml) (○) and I-A-negative resting T cells (2×10^5 per ml) (see legend to Table 1) which had been pulsed with Con A for 4 h (△). The proliferative responses were measured on day 4 and each point represents the mean value of ^{3}H-TdR uptake into DNA in triplicate cultures.

The chemical distinction between TCGF and the WEHI-3-derived activity became apparent when the latter was chromatographed on Sephadex (Fig. 2). Confirming the results in Table 1, no TCGF-like activity was observed in cultures of T-cell blasts with or without Con A (upper panel). However, activity was apparent when tested in cultures of I-A-negative populations containing resting T lymphocytes. There, fractions corresponding to an apparent MW near 20,000, inactive by themselves, supported Con A-dependent proliferation. Thus, TCGF maintains proliferation of T-cell blasts and has an apparent MW near 35,000 on Sephadex. In contrast, the activity from WEHI-3 cells has an apparent MW near 20,000, and is active in cultures of resting T cells but not on Con A-derived T-cell blasts.

These results suggested the possibility that the WEHI-3 product might support the T-cell response to Con A by allowing production or release of TCGF in the I-A-negative cell cultures. TCGF, in turn, would initiate and maintain T-cell growth. To determine whether this was the case, I-A-negative spleen cells were cultured with Con A and the partially purified WEHI-3 activity. After 24 h, the supernatant medium was collected and tested for TCGF activity in cultures of T-cell blasts. The results (Fig. 3) confirm that in the presence of both Con A and the WEHI-3 product, but not with either alone, I-A-negative cells are able to release abundant TCGF activity into the medium. Note that TCGF-dependent T-cell blasts, in contrast to unselected, resting splenic T lymphocytes, are not capable of producing TCGF (or maintaining proliferation) even in the presence of both Con A and the WEHI-3 product. This observation confirms previous negative findings when TCGF-dependent T-cell blasts were incubated with splenic macrophages and Con A (ref. 1).

These experiments show that a soluble macrophage product with an apparent MW near 20,000 is required for Con A-induced elaboration of TCGF. This product is probably identical with that known as lymphocyte activating factor (LAF). This principle is defined as a macrophage-derived factor with an apparent MW near 15,000 which is detected by its capacity to support a proliferative response of thymocytes to low, non-mitogenic concentrations of T-cell lectins such as Con A (ref. 11). LAF is known to be secreted by several macrophage cell lines including WEHI-3 (ref. 12). In this context, the data in Table 1 can be regarded as confirming earlier indications that LAF can substitute for the macrophage requirement in mitogen-dependent T-cell proliferation[13]. Also, our observations confirm and extend those of Smith and coworkers, showing that crude conditioned medium from a macrophage cell line enhanced TCGF production by non-adherent spleen cells in response to Con A (ref. 14). In agreement, we regard the requirement for adherent, I-A-positive cells in T-cell proliferative responses to be now resolved into a requirement for molecules, probably already known as LAF, which are needed only for events leading to TCGF production. Although LAF release can be induced by several macrophage-stimulating agents[15], the nature of the Con A-dependent interaction of T cells and macrophages which leads to production of LAF requires further investigation.

In addition, our results show that TCGF derives from I-A-negative cells rather than macrophages. These observations, together with those of Wagner and Rollinghoff[16] indicating involvement of Lyt-1-positive (helper) T lymphocytes in the generation of TCGF, lead us to favour the view that TCGF originates from these cells. However, our methods do not exclude the possibility that TCGF actually originates from the 3% minority contaminant of I-A- and Thy-1-negative cells, with

Table 1 Growth induction in cultures of purified resting T cells and of T-cell blasts

Addition to test culture	Responses (c.p.m. per culture × 10^{-3} ± s.d.) of anti-I-A-treated and Ig-anti-Ig column passed spleen cells*	Responses (c.p.m. per culture × 10^{-3} ± s.d.) of T-cell blasts†
None	1.3 ± 0.3	0.9 ± 0.4
Con A	2.1 ± 0.9	0.8 ± 0.3
Con A + WEHI-3 activity	31.7 ± 3.6	1.5 + 0.7
WEHI-3 activity	0.6 ± 0.3	1.2 ± 0.4
Con A + TCGF	19.7 ± 3.6	16.1 ± 2.9
TCGF	2.1 ± 0.5	17.3 ± 2.0
TCGF + WEHI-3 activity	1.7 ± 0.4	19.7 ± 3.3

* Spleen cell suspensions from C3H/HeJ mice were treated with monoclonal anti-I-A^k antibodies[18] for 30 min in the cold and passed over a column of plastic beads coated sequentially with mouse Ig and rabbit anti-mouse Ig (ref. 19). The effluent cells, now depleted of I-A-positive and Ig-positive cells, were cultured at 2×10^5 per ml in microtitre plates (0.2 ml per culture), either alone or in the presence of the following reagents as indicated: Con A (5 μg ml^{-1}), partially purified activity from WEHI-3 conditioned medium (see Fig. 2 legend) and partially purified TCGF (see Fig. 1 legend). Mean values of triplicate cultures ± s.d. of incorporated ^{3}H-TdR on day 4 of culture are presented.

† T-cell blasts (5×10^4 per ml), which had been maintained in standard CM for more than 3 weeks, were tested in the same conditions as above. The results from day 3 of culture are presented.

T lymphocytes having some other essential role. Thus, the nature of the lectin and LAF interactions with these cells leading to the release of TCGF remain unclarified. Finally, as TCGF-dependent T-cell blasts, which include killer T cells[5,9,17], are not competent to product TCGF, it seems that different T-cell subpopulations are involved in production and response to TCGF. Although the requirement for TCGF by killer T lymphocytes is clear, a fuller knowledge of the requirements of the T helper cell population is needed.

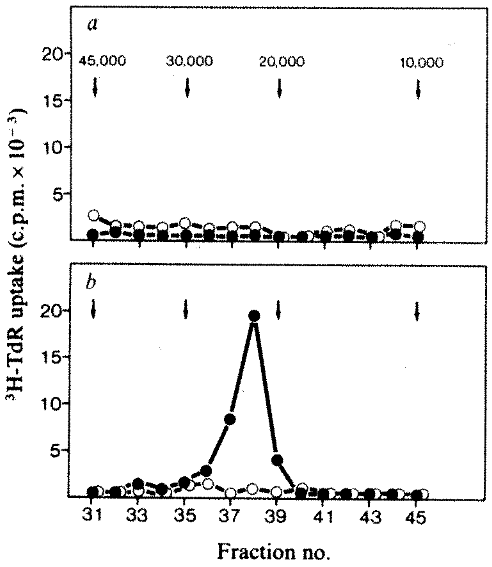

Fig. 2 Fractionation of the growth supporting activity in WEHI-3 CM. WEHI-3 CM was obtained from 5–7-d cultures of WEHI-3 cells in Iscove's modified Dulbecco's medium (IMDM) containing bovine serum albumin (BSA) (750 μg ml^{-1}), human transferrin (30 μg ml^{-1}) and soybean lipid (50 μg ml^{-1}) as described previously[14]. The WEHI-3 CM (760 ml) was concentrated by dialysis against polyethylene glycol (MW 20,000, Serva), applied to a Con A-Sepharose column (2.5×40 cm) (Pharmacia) and eluted with 50 mM Tris HCl *p*H 7.4 containing 0.5 M NaCl and 10^{-4} M Ca^{++}, Mg^{++} and Mn^{++}. The non-interactive material was concentrated over an Amicon Diaflo UM-10 membrane and thereafter applied to a Sephadex G-150 column (2.5×95 cm). Running buffer was as given in Fig. 1 legend. The growth-supporting activity was recovered in the post-albumin fractions, which were pooled and used in the experiments presented in Table 1. This pool was thereafter concentrated over a UM-10 membrane and applied to a Sephadex G-75 superfine column (1.6×90 cm) in the same running buffer as above. The fractions eluted from this column were tested for their capacity to support growth of *a*, T-cell blasts in the presence (●) or absence (○) of Con A (5 μg ml^{-1}); and *b*, purified resting T cells (see legend to Table 1) in the presence (●) or absence (○) of Con A (5 μg ml^{-1}). The proliferative responses were measured and each point represents the mean value of DNA-incorporated ^{3}H-TdR from triplicate cultures.

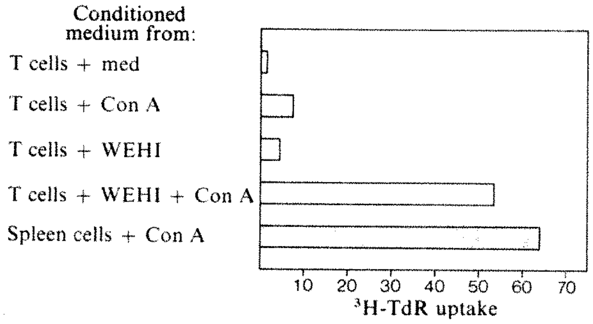

Fig. 3 WEHI-3 activity supports the Con A dependent production of TCGF by purified T cells. Spleen cells depleted of I-A-positive cells were cultured at 2.5×10^6 per ml either alone or with Con A (5 μg ml^{-1}) or partially purified WEHI-3-derived activity (pooled active fractions indicated in Fig. 2). The supernatant medium was tested for TCGF activity in T-cell blast cultures. As a positive control, normal spleen cells were cultured at 5×10^6 per ml in the presence of Con A (5 μg ml^{-1}) for 24 h. The proliferative responses were measured on day 3 of culture and the results are presented as the mean values of ^{3}H-TdR (c.p.m.×10^{-3}) incorporated into DNA in triplicate cultures.

Immunisation against heterologous type II collagen induces arthritis in mice

J. S. Courtenay, Margaret J. Dallman, A. D. Dayan, Angela Martin & Betty Mosedale

Departments of Protein Chemistry and Pathology, Wellcome Research Laboratories, Beckenham, Kent, UK

The induction of polyarthritis in rats by intradermal immunisation with homologous or heterologous type II collagen in complete or incomplete Freund's adjuvant was reported recently by Trentham *et al.*[1]. We have now produced a similar disease in certain strains of mice.

Mice were injected with either type I or type II bovine collagen, prepared using the method of Trentham *et al.*[2], emulsified in complete Freund's adjuvant (CFA) or incomplete Freund's adjuvant (ICFA), in experimental conditions similar to those known to be effective in the rat. The time of onset, and incidence of arthritis were determined by daily clinical examination, regular measurement of the thickness of hind foot pads with a micrometer gauge, and after necropsy, by histological examination of proximal and distal joints in fore and hind limbs, the tail, ear and spinal column.

The findings reported here mainly concern the induction of arthritis, clinically affecting several joints, in the DBA/1 strain of inbred mice (Laboratory Animals Centre, Carshalton). Mice aged 8–15 weeks were initially injected intradermally in the back with bovine type I or type II collagen, or the acetic acid solvent for the collagens, emulsified in CFA or ICFA. Mice were challenged 3 weeks later with an intraperitoneal injection of the same type of collagen, or of acetic acid alone.

The first sign of swelling and redness of a fore or hind paw was detected after 23 d in mice injected with type II bovine collagen in CFA. The swelling progressed to a maximum at different times in individual joints and then gradually regressed, although the joints still appeared badly damaged on histological

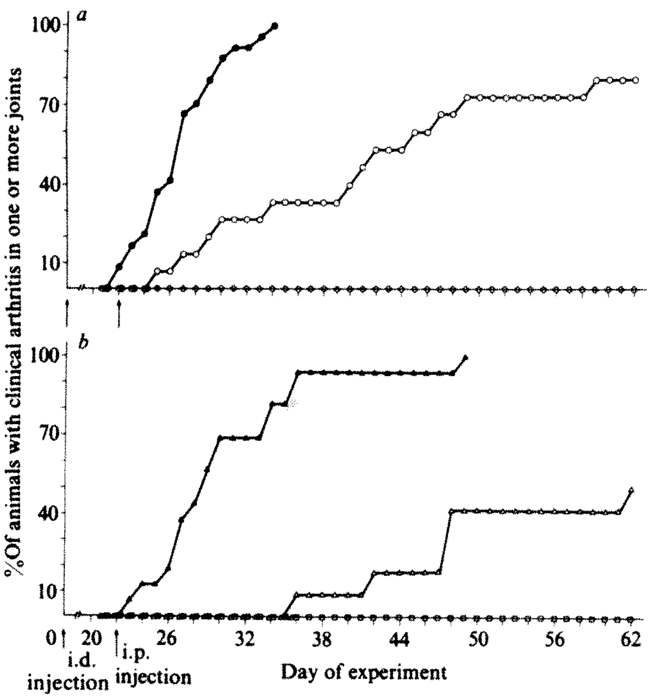

Fig. 1 Incidence and time of onset of arthritis in DBA/1 mice. DBA/1 mice were injected intradermally into 4–6 sites on the back with 100 μg of bovine type II collagen, dissolved in 0.1 ml of 0.1M acetic acid and emulsified in an equal volume of CFA (0.5 mg ml^{-1} *M. butyricum*; Difco) or ICFA (Difco) on day 0, followed on day 21 by an intraperitoneal injection of 100 μg of the same collagen type dissolved in acetic acid. *a*, Onset and incidence of arthritis in male mice given type II collagen in CFA (●); type II collagen in ICFA (○); type I collagen in CFA (◇). *b*, Onset and incidence of arthritis in female mice given type II collagen in CFA (▲); type II collagen in ICFA (△), type I collagen in CFA (□).

examination. Several joints of a single animal were often involved, sometimes so severely that the mouse had to be killed. The onset of arthritis in female mice injected with type II collagen in ICFA was delayed—swelling was never seen before day 36 in any joint. The incidence of the disease was lower in male and female mice injected with type II collagen in IFCA (67%) than in animals receiving type II collagen in CFA (100%).

The incidence and day of onset of arthritis in mice injected in four separate experiments are shown in Fig. 1. Of 40 mice injected with type II collagen in CFA, all developed arthritis, compared with 18 of 27 injected with type II collagen in ICFA. None of the 12 mice injected with type I collagen in CFA, or of the 17 mice injected with acetic acid and CFA, showed signs of the disease (Table 1).

Histological examination of affected joints from animals receiving type II collagen either in CFA or ICFA revealed initial oedema of the synovium and perisynovial tissues, followed by synovial hyperplasia. There was an early massive, predominantly polymorph and subsequent mononuclear cell infiltration into the synovium, sub-synovium, joint cavity and periarticular tissue. This was followed by pannus development, fibrin deposition, and cartilage and bone erosion with new bone formation. Late in the course of the disease the cellular infiltration and oedema were reduced, but by then many joints had become ankylosed, and most recognisable synovium and joint cartilage had been destroyed. The vertebrae were rarely affected, involvement occurring only several weeks after initial peripheral joint swelling. Very occasional, small inflammatory foci in the ear or tail were seen in a few animals.

Several important negative observations were made. There was no clinical or histological evidence of arthritis after injection of type I bovine collagen or acetic acid in CFA. Uninoculated control animals kept in the same cage as mice injected with type II collagen in CFA did not develop any clinical or postmortem evidence of arthritis. Synovial cavity washes of affected and unaffected joints from 17 DBA/1 mice were cultured for mycoplasma and all gave negative results. There was no significant growth of bacteria when synovial cavity washes from one unaffected and four affected animals were cultured anaerobically and aerobically, and no bacteria were seen in histological preparations of joints.

There are differences between the disease in the rat as described by Trentham *et al.*[1] and that seen in the mouse. Arthritis in the rat appeared earlier and it could be produced by immunisation with antigen in either CFA or ICFA. Mice responded less well to use of ICFA as adjuvant. A single intradermal injection has produced the disease in the rat, but only a schedule of initial intradermal immunisation followed by a subsequent challenge has been used in the mouse. We have found in both species, that involvement of second, third and fourth paws may occur up to 4 weeks after swelling of the first joint and that the number of joints affected varies between animals. The histology in the two species is similar.

Initial studies in other strains of mice treated in the same fashion showed that arthritis may sometimes be produced, but its clinical and histological incidence was variable, and the severity has been less than in the DBA/1 mice: SWR (major histocompatibility type H-2q)—4/15 (total number with clinical or histological lesions/total number treated); SJL (H-2s)—4/6, BALB/c (H-2d)—4/27; BlO.G (H-2q)—4/11; DBA/1 mice from the Jackson Laboratory, Bar Harbour, Maine—2/5 (the Carshalton colony was derived from this colony 25 years ago (M. W. Festing, personal communication); male and female mice from both colonies are histocompatible on skin grafting and *in vitro* mixed lymphocyte culture (L. Berumen, personal communication). Groups of 5–10 mice of the following strains did not develop any joint lesion after treatment with collagen type I or II in CFA or ICFA—C57Bl/10scSn (H-2b), CBA/CA (H-2k), BlO.A (5R) (H-2i5), BlOBR (H-2k) and DBA/2 (H-2d).

It is known that the immune response to the native helical portion of the bovine type II collagen molecule differs in strains of inbred mice[3] and that the response appears to be under H-2 linked control[4]. Trentham *et al.*[5] have shown that in rats the conformational antigenic site on the collagen molecule is important in induction of arthritis, since isolated α-chains of type II collagen did not produce arthritis when injected intradermally in either CFA or ICFA. Initial work has been undertaken here to study the anti-type II collagen antibody response in susceptible and resistant strains of mice, the role of the histocompatibility type and to examine the immunological processes involved.

Table 1 The incidence of arthritis induced by bovine collagen type II in DBA/1 mice

	Bovine collagen type given on day 0 and on day 21	Adjuvant given on day 0	No. of mice affected by day 62/total mice given treatment
Male	II	CFA	24/24
	—	CFA	0/10
	—	-	0/5*
	II	ICFA	12/15
	—	ICFA	0/4
	I	CFA	0/5
Female	II	CFA	16/16
	—	CFA	0/7
	II	ICFA	6/12
	I	CFA	0/7

* Kept in same cage as affected animals.

The finding that an arthritis develops in mice after immunisation with type II collagen lends some support to the hypothesis of Trentham *et al.*[1] that an immune reaction to collagen may be involved in the pathogenesis of arthritis. Use of the mouse disease as a model should avoid the risk of adjuvant arthritis common to experiments in the rat, and it should also permit ready analysis of the role of histocompatibility type and immune response genes.

We thank Drs M. W. Festing and M. Weatherall for help and advice, and Ms Auriol Hill, Dr G. D. B. Windsor and Mr R. Foreman for testing synovial fluid for bacterial infection.

Human antibody reacts with a B-cell subset in man to induce B-cell differentiation

Jean Claude Brouet, Catherine Grillot-Courvalin, & Maxime Seligmann

Laboratory of Immunochemistry and Immunopathology
(INSERM U108, Research Institute on Blood Diseases and
Laboratory of Oncology and Immunohematology of CNRS),
Hospital Saint-Louis, 75475 Paris, Cedex 10, France

The events leading to B-cell differentiation and maturation into plasma cells in man are still poorly defined. Human B-cell differentiation has mainly been studied after triggering by nonspecific mitogens which react with unknown B-cell-surface structures. T cells and T-cell factors play an important part in this B-cell activation[1]. It is therefore interesting that we found that some patients with the rare immunodeficiency disease, the Wiskott-Aldrich (WA) syndrome, possess an IgM antibody which reacts only with a subset of human B-cells from the peripheral blood and tonsils and which is able to induce B cells to differentiate into plasma cells *in vitro*. This triggering is largely independent of T cells and in certain conditions occurs in the absence of detectable B-cell proliferation. In view of certain recent findings in some immunologically defective strains of mice such as CBA/N, genetic immunodeficiencies in man may represent useful models for investigating human B-cell subsets and the process of B-cell activation. We have therefore looked for B-cell antibodies in the serum of WA patients because, in addition to an immune defect of poorly understood mechanism[2], these patients have major thrombocytopenia and are therefore multi-transfused. We found that the serum of seven of nine WA patients contained an antibody reacting by cytotoxicity and immunofluorescence tests with a subset of both normal human and, unexpectedly, of the patients' own B cells.

A two-step double labelling procedure was used for the immunofluorescence experiments. In the first step, membrane-bound B-cell immunoglobulins (Ig) were redistributed with fluoresceinated IgG or F(ab')$_2$ fragments from antibodies to human Ig (or μ chains), allowing the enumeration and identification of B cells. In the second step, the cells were incubated in non-capping conditions with heat-inactivated sera of the various patients or controls, washed and finally stained with rhodamine-conjugated F(ab')$_2$ fragments of monospecific rabbit IgG antibodies to human Ig chains[3]. Whereas the control sera, including 15 patients with varied immunodeficiencies, did not stain a sizeable population of B cells, the serum of seven WA patients reacted with 30–60% of B cells from human tonsils and from the peripheral blood of all 30 normal donors tested. The antibody belongs to the IgM class and is polyclonal because the 19S (and not 7S) fraction obtained by preparative ultracentrifugation of the serum in a sucrose density gradient was reactive and, in immunofluorescence tests staining was observed only using F(ab')$_2$ fragments of antibodies to μ, κ and λ chains (and not to γ, α or δ). Most sera had a titre of 1/4 to 1/16 and reacted with B cells at both 4 °C and 37 °C. Two sera had an end point of 1/32 and 1/128 respectively and were also studied by cytotoxicity at 25 °C on purified B- and T-cell populations from selected donors with various HLA phenotypes. These experiments confirmed that the antibodies were unreactive with T cells and killed a subset of B cells.

The reactive antigenic determinant on the surface of B cells is independent of surface Ig (and specially IgD) as shown by double-labelling and redistribution experiments. Double labelling experiments also showed that the reactive structure is unrelated to Ia-like (or Dr) antigens, as could be expected in view of its presence on only a B-cell subset. For the same reason it seems very unlikely that the WA antibody reacts with other well defined B-cell-surface molecules such as the receptors of IgG, IgM, complement components, or Epstein–Barr virus. In addition it should be recalled that the antibody was unreactive with T cells and monocytes, as well as red cells and platelets.

The antigenic structure is presumably a marker of a unique subset of B cells and does not seem to be a differentiation antigen since we found that it is expressed on pre-B cells of a patient with pre-B-cell acute lymphoblastic leukaemia, on all leukaemic cells from two of five patients with B-derived chronic lymphocytic leukaemia and on the plasma cells from two of four myeloma cases. Experiments to define the biochemical properties and molecular weight of this antigenic structure are in progress. It is probably distinct from the glycoprotein of molecular weight 54,000 (gp 54), recognised by a rabbit antiserum and recently described by Wang *et al.*[4], which is also a marker of a subset of human B cells, since interaction of these surface molecules with their specific antibodies mediates different functional effects.

Whereas antibodies to the gp 54 antigen stimulated B lymphocytes to proliferate but not to differentiate into plasma cells, we found that the WA antibody does induce B-cell maturation. Table 1 shows that when peripheral blood lymphocytes were cultured in the presence of 1% WA serum (or its 19S fraction at a concentration of 10 μg ml^{-1}), a 5- to 20-fold increase in the percentage of plasma cells above control cultures was found on day 7, together with a striking cell proliferation and increase in surface Ig-positive cells. The pattern which was

Table 1 *In vitro* induction of B-cell differentiation by WA serum

	NHS	0.5	1	0	0	8	4	2

Mononuclear cells from peripheral blood were isolated by Ficoll–Hypaque gradient. The cells were washed three times in RPMI medium 1640 containing 10% FCS and antibiotics. 5×10^6 cells were incubated for 7 days in a 5% CO_2/95% air incubator in 5 ml of the same medium containing 1% WA serum, 1% normal human serum (NHS) or 50 μg ml^{-1} PWM. On day 7, cells were washed and studied for surface and cytoplasmic Ig by direct immunofluorescence with monospecific antisera to human Ig heavy chains.

* Percentage of positive cells.

Table 2 *In vitro* induction of B-cell differentiation by WA serum using B-cell enriched or unseparated PBL and two different batches of FCS

		Unseparated PBL			E-rosette-depleted PBL		
		WA serum	NHS	PWM	WA serum	NHS	PWM

Expt 3	cIg*	1.5	<0.1	10	3.5	<0.2	0.5
	SIg*	34	7	17	66	18	40

Unseparated peripheral blood lymphocytes (PBL) or B-cell enriched populations obtained by Ficoll–Hypaque gradient separation of lymphocytes rosetted with neuraminidase-treated sheep erythrocytes (two successive separations) were cultured for 7 days with 1% WA serum, 1% normal human serum (NHS) or PWM as described in Table 1. Experiment 1 was performed with the batch of FCS used in Table 1 whereas experiments 2 and 3 were performed with another batch of FCS (see text).

* Percentage of positive cells.

observed was very close to that of pokeweed mitogen (PWM)-induced B-cell differentiation and the isotype distribution of intracytoplasmic Ig showed a slight predominance of IgM over IgG and IgA plasma cells. These figures were obtained with a given batch of fetal calf serum (FCS). When using another batch of FCS, there was still a 5- to 10-fold increase in the percentage of Ig-bearing immunoblasts and of plasma cells in the presence of the WA antibody as compared with normal serum. However, in these conditions, the number of plasma cells in the culture was smaller and the differentiation of B lymphocytes occurred without detectable cell proliferation, as assessed by the absence of thymidine uptake on any day during the period of culture. The discrepancy between these two sets of results using different batches of FCS was explained by the study of the effect of the WA antibodies on purified B cells. When using such purified B-cell preparations, the cell recovery and plasma cell number were similar for both batches of FCS (Table 2). We therefore conclude that B-cell differentiation induced by the WA antibody can occur after depletion of T cells. T cells are needed to obtain B-cell proliferation and optimal differentiation; this T-cell effect requires the presence of a supportive batch of FCS.

Since PWM probably only acts on a given B-cell population[1], experiments were designed to investigate possible relationships between the B-cell subset reacting with the WA antibody and that responsive to PWM. There was no additive effect when lymphocytes were cultured in the presence of both PWM and WA serum. On the other hand, the depletion by cytotoxicity of those B cells reactive with the WA antibody resulted in a 60–80% decrease in the number of plasma cells obtained in PWM-stimulated cultures. These results show that the two B-cell subsets are similar or at least overlapping. Since PWM-induced B-cell differentiation is mediated by T-cell factors, it is worth investigating possible interactions between the WA antibody and a receptor for T-cell helper factors.

These experiments demonstrate that the antibodies to a subset of B cells found in the serum of some patients with the WA syndrome interact with a surface molecule involved in B-cell triggering. To our knowledge, such antibodies have not previously been described in man. Their properties are somewhat reminiscent of those of antibodies directed to the receptor for lipopolysaccharide on mouse B cells[5] and of anti-Ly 3 antibodies which markedly enhance the development of antigen-specific plaque-forming cells[6]. The surface antigen defined by our antibody may be similar to the murine Ly 3 antigen which is a marker of the B-cell subset absent in CBA/N mice[6]. The availability of the human antibody described here may help to characterise such human lymphocyte markers and to obtain insights into the control of human B-cell activation.

Osteoclasts derived from haematopoietic stem cells

Patricia Ash, J. F. Loutit & K. M. S. Townsend

Medical Research Council, Radiobiology Unit,
Harwell, Didcot, Oxon OX11 0RD, UK

The origins of the multinucleated osteoclast have been controversial, with osteogenic precursors[1] and haematopoietic stem cells[2] as candidates. Recent evidence for the latter is persuasive but circumstantial. We report here direct evidence obtained in radiation chimaeras from a natural cytoplasmic cell marker transmitted by the donated haematopoietic stem cell.

Beige mice (Chediak-Higashi syndrome) have giant lysosomes, present in granular leukocytes and monocytes[3] and osteoclasts[4]. Lethally X-ray irradiated (600 rad) osteopetrotic weanling microphthalmic (*mi*/*mi*) mice have been converted to radiation chimaeras[5], by intravenous infusion of bone marrow from beige (*bg*/*bg*) mice. This gives complete regeneration of the lymphomyeloid complex from donor's haematopoietic stem cells, but osteogenic cells and their precursors remain of host-type[6,7]. In the course of restoration, the osteopetrosis, attributed to a genetic defect of osteoclastic mechanisms, is cured[8,9], the process being evident after 2 weeks, advanced at 4 weeks and complete by 6 weeks.

Table 1 shows that the per cent area of giant lysosomal granules in osteoclasts observed electron micrographically increases from a baseline of near zero to 0.15% at 2–4 weeks, a difference statistically significant ($P < 0.001$) but not impressive to a visual observer; at 6 weeks this is nearly 2%, the figure observed for beige mice[4]. This level persists until the last observations, made after 4 months; that is, the osteoclasts of the chimaera, like the granular cells, notably eosinophils, exhibit the characteristics of the beige mouse donor. Osteoblasts remained without giant lysosomes.

Table 1 The per cent area of osteoclasts occupied by giant lysosomes ($>1\ \mu$m diameter)

Group	Days after transplant (no. in groups)	Mean % of osteoclast area due to giant lysosomes	
Experimental	14 (1)	0.18	$\bar{x} = 0.15 \pm 0.004$
	28 (3)	0.12	
	42 (3)	1.84	$\bar{x} = 1.89 \pm 0.35$
	56 (3)	1.87	
	120 (2)	1.99_5	
Control CBA	— (5)	0.02	$\bar{x} = 0.018 \pm 0.008$
Control *mi*/*mi*	— (5)	0.016	
Control *bg*/*bg*	— (5)	2.09 ± 0.58	

For each animal, 30–40 photographs of osteoclasts, observed electron micrographically in metaphyses of femora and ilia, were taken at a magnification of ×3,000, two to five pictures being required to cover what seemed to be a single osteoclast. The photographic negatives were analysed on a Quantimet (Cambridge Instruments). The measurements of area in picture points were converted to μm^2. A computer program was written to coordinate osteoclast area and number of, and area occupied by, giant lysosomes.

0028–0836/80/070669—02$01.00

We conclude that the ultimate osteoclasts of the chimaera derive from the haematopoietic stem cells of the beige mouse donor. During the first 2–4 weeks, resolution of the osteopetrosis proceeded steadily. Then, the osteoclasts with brush borders observed electron micrographically, although not yet formally enumerated, became more common than in normal mouse bone. However, the emergence of the lysosomal marker in these cells was variable, observable but not impressive. There may be several explanations for this: (1) only a minor population of donor's osteoclasts may be adequate for the job of clearing the redundant bone. (2) Osteoclasis was being pushed to its limit. Osteoclasts working overtime may not form giant lysosomes by fusion of small lysosomes. (3) Osteoclasis of this degree may be a function of uninucleated precursor cells[10,11] not scored in our investigation. Other elements of the mononuclear phagocyte system, such as tissue phagocytes[2], have been invoked in osteoclasis, and blood monocytes are reported to be lytic for dead bone[12,13]. (4) The graft of myeloid tissue confirmed in other investigations[14,15] by the nuclear marker (T6 chromosome) may have the additional ability to repair the defect of the host's osteoclasts by short-range exchange of 'information', that is, plesiopathy (πλησίος, near; πάθος, experience) as between lymphocytes and cells of the mononuclear phagocyte system.

Pacemaker currents in chick embryonic heart cells change with development

Alvin Shrier* & John R. Clay†

Department of Anatomy, Emory University, Atlanta, Georgia 30322

The initial heartbeat of the chick embryo occurs shortly after the first day of incubation[1,2]. The pacemaker of this beat originates in the region of the primitive heart destined to become sino-atrial tissue in the adult[3]. Individual cells isolated from the atrial and ventricular portions of the embryonic heart are also capable of beating spontaneously at this stage[4,5]. However, the intrinsic activity of these cells gradually diminishes from about day 7 until day 21 when the chick hatches[5]. We have investigated these changes in automaticity by measuring membrane pacemaker currents with the voltage-clamp technique from aggregates of cells prepared from 7-, 12- and 17-day-old chick embryo cardiac ventricle. We report that there is a voltage and time dependent conductance at 7 days which is markedly reduced by 17 days. The reduction of this pacemaker current parallels the decrease of spontaneous activity in these preparations.

Spheroidal heart cell aggregates (HCA) were prepared using techniques previously described[6]. Briefly, the apical portions of heart ventricles were dissected from chick embryos incubated for 7, 12 or 17 days at 37 °C. The tissue was dissociated into its component cells in 0.05% trypsin (1:300 Nutritional Biochemical) by a multiple cycle dissociation process[7]. Cells were allowed to reaggregate in a flask containing tissue culture medium which was placed on a gyratory shaker for 48–72 h. During gyration HCA were formed which were typically from 100 to 300 μm in diameter (D). The HCA were allowed to adhere to the bottom of a tissue culture dish containing medium 818A (ref. 6). Potassium concentrations (K_o) used ranged between 1.3 and 6 mM. The temperature of the dish was maintained at 37 °C (continuously monitored). Intracellular electrical recordings were made with glass microelectrodes filled with 3M KCl (resistance 15–50 MΩ). Measurements from all three developmental stages were made in the presence of 3 μM tetrodotoxin (Sigma) which acted to block the fast inward sodium current which seems to be fully developed before day 7 (ref. 8). Voltage-clamp measurements were performed with standard circuitry[9] on aggregates with $D = 180$–220 μm. Current was recorded from the voltage drop across a 10-MΩ feedback resistor of an operational amplifier (Analog Devices, Model 48K) which held the bathing medium at virtual ground via an agar salt bridge and an Ag:AgCl wire. The HCA is suitable for a voltage clamp study of pacemaker currents because: (1) the cells are well-coupled[10,11]; (2) the specific membrane resistance is large for pacemaker potentials[12]; (3) most of the cells are in the two or three outermost layers of the preparation because of its spherical geometry; and (4) the extracellular cleft spaces are relatively large[12,13].

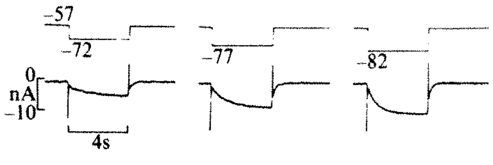

Fig. 1 Voltage clamp records from 7 day HCA in 1.3 mM K_o. Rise time of voltage control was 5–15 ms. Current records were filtered with a low pass filter having 3 dB cutoff at 50 Hz.

The responses to rectangular voltage clamp steps at 7 days in 1.3 mM K_o are shown in Fig. 1. These steps produced a time-

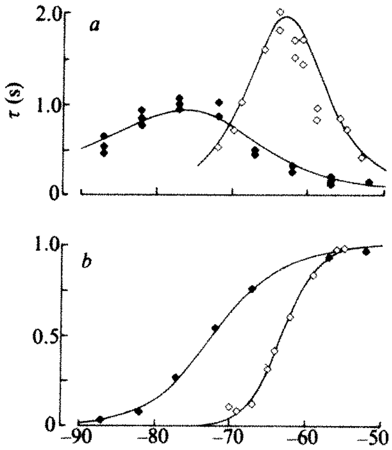

Fig. 2 Analysis of time-dependent currents in 7 (◆) and 12 (◇) day HCA. The currents from all developmental stages could be described by a single exponential function with time constant τ. For each pulse record τ was determined from a photograph or an oscilloscope trace using a Hewlett-Packard 9810A calculator, 9864A digitiser, and 9862A plotter. Solid lines are theoretical best fits to each set of data using modified forms of the model of pacemaker current in cardiac Purkinje fibre of McAllister *et al.*[17]. *a*, Voltage dependence of the time constant (τ) obtained from a single 7 or 12 day HCA pooled in each case from 4 different holding potentials. *b*, Normalized current amplitude on return to a single holding potential obtained by the method in ref. 14.

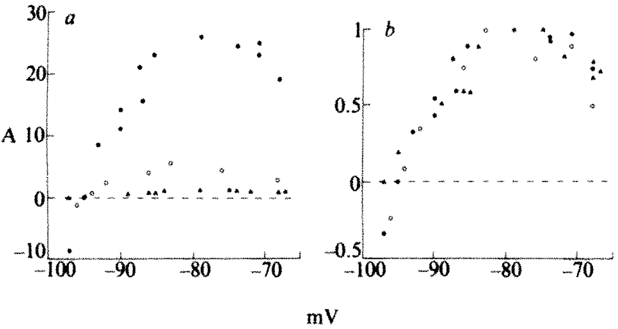

Fig. 3 *a*, Pacemaker channel current–voltage relationship[14] for 7 (●), 12 (○) and 17 day (▲) HCA in 3.5 mM K_o. The points were from a single preparation at each developmental stage. *b*, Normalised channel current–voltage relationships obtained by dividing each set of points in *a* by the corresponding peak current (I_p).

dependent change in membrane current which reached a steady final level corresponding to the voltage to which the membrane was clamped during the step. Successively smaller time-dependent currents were observed at 12 and 17 days, respectively, in the −55 to −120 mV range of membrane potentials. The current changes in this voltage range obeyed first order kinetics amenable to standard Hodgkin-Huxley analysis[14–16] (Fig. 2). The maximum time constant was 1 s at 7 days compared to 2 s at 12 days (Fig. 2*a*), and the range of activation of the kinetics was narrower at 12 days than at 7 days (Fig. 2*b*). The voltage at which the maximum time constant occurred at 12 days appeared to be shifted in the positive direction. The kinetics and the voltage at which the maximum time constant occurred at 17 days were both approximately the same as those at 12 days. Changes of K_o in the 1.3 to 6 mM range did not alter the voltage range or the time scale of the kinetics.

The amplitude of this pacemaker current may be ascribed to ion flow through membrane channels, each of which is gated by a particle having kinetics as described in Fig. 2. The voltage dependence of the channel current may be determined from the ratio of the time-dependent current change during the clamp step to the time-dependent current change after the voltage returns to the holding potential[14]. The results of this analysis for the three developmental stages in K_o of 3.5 mM are shown in Fig. 3*a*. The current inwardly rectifies and has a negative slope region positive to −80 mV. The relative voltage dependence of the channel current was nearly the same at all three stages (Fig. 3*b*). The peak channel current (I_p) was approximately independent of K_o, although the voltage at which I_p occurred was shifted by K_o and the reversal potential of the channel current changed with K_o like a potassium electrode. The pooled results for I_p were 27.2 ± 2.6 nA (±s.d., $n = 7$) at 7 days, 3.4 ± 1.1 nA ($n = 5$) at 12 days and 0.8 ± 0.4 ($n = 5$) at 17days. The reduction of this current could be produced either by a reduction of the channel density or by a reduction of the single channel conductance.

This study is the first analysis of the changes occurring in the ionic pacemaker currents of heart muscle cells during embryonic development. The contribution of the pacemaker current we have described to the control of beat frequency requires analysis of the time-independent current in the pacemaker voltage range, which also changes during development. This current becomes less inward with development and seems to be the dominant factor responsible for the loss of automaticity in these preparations.

PGE_2 stimulates gastric chloride transport: possible key to cytoprotection

Rudolf Schiessel, Jeffrey Matthews, Ami Barzilai, Aryeh Merhav & William Silen

Departments of Surgery, Harvard Medical School, Beth Israel Hospital, 330 Brookline Avenue, Boston, Massachusetts 02215

Prostaglandins protect the stomach against a variety of noxious agents independently of effects on acid secretion, but the mechanism of this 'cytoprotection' is unknown[1]. We recently proposed[2] that gastric surface cells extrude or eliminate luminal acid by a process analogous to that described in squid axon[3], snail neurone[4], and barnacle muscle[5]. Influxing luminal H^+ combines with HCO_3^- which has entered the cell in exchange for intracellular chloride, probably at the nutrient membrane. Dehydration of the resulting H_2CO_3 into CO_2 and H_2O is catalysed by carbonic anhydrase, which is present in surface cells in large amounts[6]. Interference with this chain of reactions at any point frequently causes ulceration[2]. We have examined the effect of 16,16-dimethylprostaglandin E_2 (PGE) on different segments of this protective mechanism and show here that the protective effects are intimately associated with stimulation of chloride transport. All experiments were done *in vitro* thus eliminating any effects of prostaglandin on mucosal circulation.

Fundic or antral mucosa of bullfrogs (*Rana catesbeiana*) were mounted in lucite chambers after the frog was pithed and the muscular coat stripped from the mucosa[2]. The flux of $^{36}Cl^-$ was measured from nutrient (N) to secretory (S) solutions ($J_{Cl_{ns}}$), and vice versa ($J_{Cl_{sn}}$) in paired (fundus) and unpaired (antrum) tissues while the potential difference (p.d.), resistance (R) and short-circuit current (I_{sc}) were recorded[7]. Under standard open circuit conditions 10^{-5} M PGE caused a transient decrease followed at 60 min by a significant increase in $J_{Cl_{ns}}$. A concomitant rise in $J_{Cl_{sn}}$ and I_{sc} was observed. The increase in I_{sc} is probably caused by the fact that the inhibition of H^+ secretion is not accompanied by a decrease in the net transport of Cl^- (Fig. 1). Similar increases in unidirectional J_{Cl} were observed in short-circuited antrum except that the initial drop in $J_{Cl_{ns}}$ was not present (Fig. 2). The marked decrease in $J_{Cl_{ns}}$ and $J_{Cl_{sn}}$ noted when HCO_3^- is removed from the nutrient solution in metiamide-inhibited tissues was not influenced by the presence of 10^{-5} M PGE in N ($n = 4$). Addition of 4 mM SITS (4-acetamido-4′-isothiocyano-stilbene-2,2′ disulphonic acid) known to block anion transport in a variety of tissues, to N of fundic mucosa for 160 min decreased $J_{Cl_{ns}}$ from 9.49 ± 0.96 to 4.72 ± 1.03 μ Eq h^{-1} cm^{-2} and $J_{Cl_{sn}}$ from 5.64 ± 1.07 to 3.01 ± 0.44 μ Eq h^{-1} cm^{-2}, (mean ±s.e.; $n = 3$) and also reduced the p.d. and I_{sc} by 28.2% and 42.6% respectively. Histamine-stimulated H^+ secretion was decreased 49% by SITS. When 10^{-5} M PGE was added to fundic mucosae

0028–0836/80/070671—03$01.00

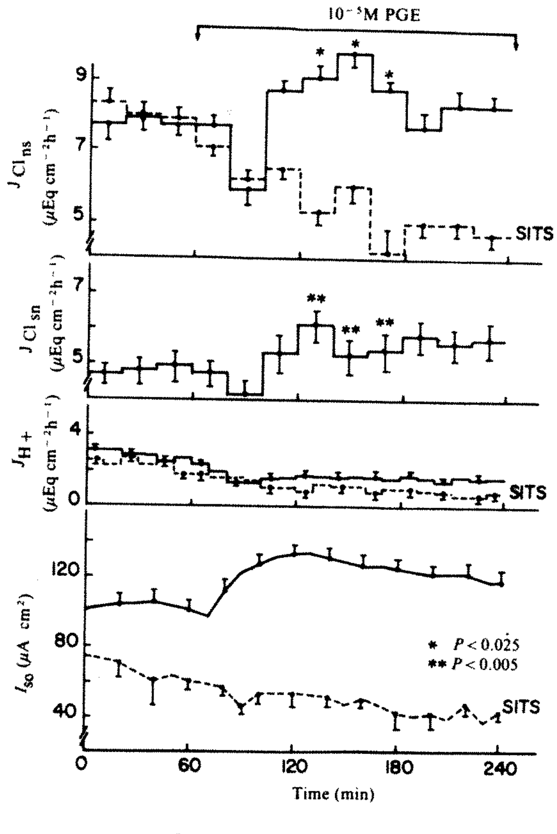

Fig. 1 Effect of 10^{-5} M PGE on Cl^- transport in fundus under open circuit conditions. The bathing solutions contained (in mM) 95 NaCl, 23 Na isethionate on the secretory side and 87 NaCl, 18 $NaHCO_3$, 4 KCl, 2 $CaCl_2$, 1 $MgCl_2$, 1 KM_2PO_4 and 10 mM glucose on the nutrient side and were gassed with 95% O_2–5% CO_2. At 60 min after adding PGE, $J_{Cl_{ns}}$ ($n = 7$) and $J_{Cl_{sn}}$ ($n = 7$) increased significantly over the baseline values. This did not occur in 7 untreated controls. PGE inhibited H^+ secretion and increased p.d. from 28.6±2.53 to 38.4±1.73 mV (mean±s.e.) 60 min after application. R remained stable during this period (205±15.9 to 206±18.52 cm²). Pretreatment with SITS, 4×10^{-3} M for 60 min led to a decrease in $J_{Cl_{ns}}$ ($n = 6$) which was not influenced by PGE. Data from baseline and test periods were evaluated by Duncan's test. Comparisons between the means of these two periods were made by the t-test for paired values.

Table 1 Ulceration of gastric sacs

Buffer	Gas	n	Ulcerated	P
Control				
5 mM PO_4^{3-}	100% O_2	16	14	0.004
PG-pretreatment				
5 mM PO_4^{3-}	100% O_2	16	6	NS
5 mM PO_4^{3-} (Cl^--free)	100% O_2	16	11	
Control				
SITS+5 mM PO_4^{3-}	100%	8	8	
SITS+18 mM HCO_3^-	95% O_2–5% CO_2	8	4	
PG-pretreatment				
SITS+18 mM HCO_3^-	95% O_2–5% CO_2	8	4	
SITS+5 mM PO_4^{3-}	100% O_2	8	7	

Tied sacs of inverted gastric mucosa (mucosa inside) were incubated in different nutrient buffers circulated by the indicated gas. After 1 ml of artificial gastric juice, containing 40 mg % pepsin and 20 mM HCl, had been instilled into the sac lumen, the tissue was incubated for 4 hours. PG-pretreatment means addition of 3×10^{-6} M PGE 60 min before instillation of artificial gastric juice. The Fisher's exact test was used for statistical evaluation. NS, not significant.

pretreated with SITS, 4 mM no effect on $J_{Cl_{ns}}$ was observed (Fig. 1).

Forte[7] has described three components of $J_{Cl_{ns}}$ in amphibian gastric mucosa. In addition to the component of active transport dependent on the presence of O_2 and to a small diffusional component, a major fraction of $J_{Cl_{ns}}$ is represented by exchange diffusion dependent on the presence of Cl^- in the secretory solution. Since we postulate that the availability and exchange of cellular Cl^- for nutrient HCO_3^- are vital for protection of surface cells against luminal H^+, we tested the effect of PGE on exchange diffusion according to Forte[7]. When Cl^- was removed from the secretory solution, PGE was unable to maintain a normal exchange diffusion of Cl^- from N to S (Fig. 3), indicating that the increased Cl^- fluxes across the tissues induced by PGE are more likely a result of increases in exchange of HCO_3^- for Cl^-, than a direct stimulation of the Cl^- pump.

Prostaglandins stimulate an adenylate cyclase in surface cells but not the histamine-stimulated cyclase of oxyntic cells[8]. We added 10^{-3} M N^2-O^6-dibutyryl cyclic AMP to N, of short-circuited antral mucosa and found that $J_{Cl_{ns}}$ increased markedly within 40 min (Fig. 2).

To test the relationship of these findings to the known cytoprotective effects of PGE, we studied tied sacs of fundic mucosa of the same species known to ulcerate almost invariably in the absence of nutrient HCO_3^- (refs 2, 9). Ulceration was prevented to a highly significant degree by 3×10^{-6} M PGE, in the absence of nutrient HCO_3^- but not when Cl^- was replaced by isethionate and SO_4^{2-} in the bathing solution (Table 1). In sacs pretreated with 4 mM SITS, PGE failed to prevent ulceration not only in the absence of nutrient HCO_3^- but even when 18 mM HCO_3^- was present in the nutrient solution (Table 1). The protection afforded by the presence of HCO_3^- in tissues exposed to SITS was not enhanced by PGE.

We conclude that PGE stimulates $J_{Cl_{ns}}$ and $J_{Cl_{sn}}$ in a process possibly involving cyclic AMP. The failure of PGE to preserve forward Cl^- flux in the absence of Cl^- in the secretory solution suggests that PGE stimulates the exchange of cellular Cl^- for nutrient HCO_3^-, a vital step in the protection of the surface cell against the hostile environment of luminal acid. The importance of the availability of nutrient HCO_3^- for such an exchange is emphasised by recent studies (in preparation) showing that

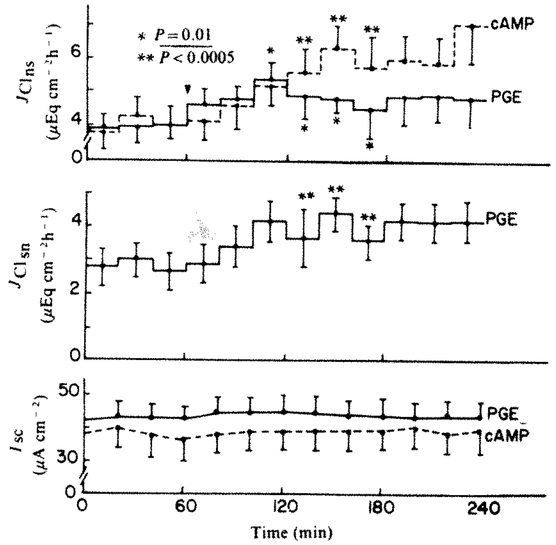

Fig. 2 Effect of 10^{-5} M PGE on Cl^- transport in antrum under short-circuit conditions. $J_{Cl_{ns}}$ ($n = 8$) and $J_{Cl_{sn}}$ ($n = 6$) increased significantly over the baseline period values. This did not occur in 8 untreated controls. Cyclic AMP 10^{-3} M also increased $J_{Cl_{ns}}$. Arrow indicates addition of drug to the nutrient solution. Data evaluated as for Fig. 1.

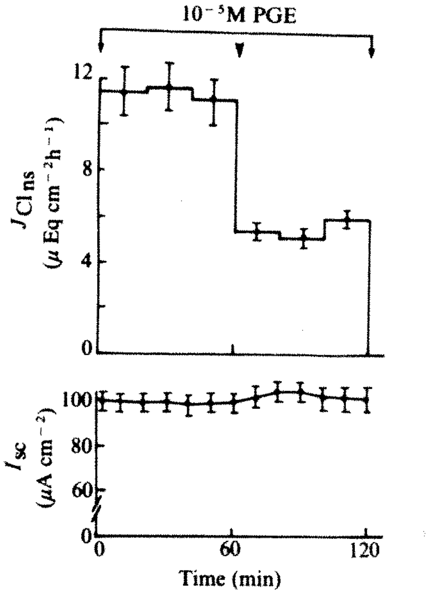

Fig. 3 Effect of 10^{-5}M PGE on the exchange diffusion component of $J_{\mathrm{Cl_{ns}}}$. At the arrow the secretory solution was replaced with 118 mM Na isethionate and 2 mM K_2SO_4. Duncan's test was used for statistical evaluation.

protection of the mucosa can be achieved with either a high concentration of nutrient HCO_3^- or by the actively stimulated oxyntic cell and its consequent alkaline tide. The protective mechanisms of the gastric epithelial surface cell bear many analogies to the acid extruding pump demonstrated in other tissues[3-5].

Muscarinic suppression of a novel voltage-sensitive K^+ current in a vertebrate neurone

D. A. Brown* & P. R. Adams

Department of Physiology and Biophysics, University of Texas Medical Branch, Galveston, Texas 77550

Cholinergic excitation of vertebrate neurones is frequently mediated through the action of acetylcholine on muscarinic (atropine-sensitive) receptors. This type of excitation differs substantially from the better known nicotinic excitation. One difference is that, instead of an increased membrane conductance, a decreased conductance (to K^+ ions) frequently accompanies muscarinic depolarisation. This has been detected in sympathetic[1-4], cortical[5] and hippocampal[6] neurones. Using voltage-clamped frog sympathetic neurones we have now identified a distinctive voltage-sensitive K^+-current, separate from the delayed rectifier current, as the prime target for muscarinic agonists. We have termed this current the M-current, I_M.

For our experiments we used isolated lumbar sympathetic ganglia from bullfrogs (*Rana catesbiana*), from which the connective tissue was removed with trypsin (1% for 10–15 min): this treatment did not materially affect the currents under study. The ganglia were perfused with Ringer's solution at 22 °C containing 2.5 mM KCl, 2 mM $CaCl_2$, 2 mM Tris (buffered to *p*H 7.2 with HCl), and (usually) 10 mM $MgCl_2$ to improve electrode sealing. Individual cells were impaled with two microelectrodes filled with 3M KCl (resistances 20–50 MΩ), one for recording membrane potential and one for passing or recording current.

Some general properties of the M-current are illustrated in Fig. 1. This cell was held under voltage-clamp at a relatively depolarised membrane potential (−30 mV), at which there is normally a substantial and steady outward M-current. On applying a hyperpolarising step-command, the channels carrying the M-current gradually close, giving rise to a slow inward current relaxation after the initial fast ohmic step. Channel closure is indicated by the fact that the membrane conductance falls during this relaxation, the ohmic step at the end of the command being smaller than that at the beginning. Repolarisation then produces a slow outward relaxation as the M-channels open again. (On repolarising from membrane potentials more negative than −70 mV the currents are complicated by the appearance of another, more transient outward current analogous to the rapidly inactivating A-current reported in molluscan neurones[7,8].)

With increasing step-commands the inward relaxation reversed in direction at command potentials between −70 and −100 mV (−74 mV in Fig. 1). This reversal potential shifted in the depolarising direction by 20–25 mV on raising $[K^+]$out from 2.5 to 8 mM, and by 40–55 mV at 25 mM. Thus, I_M is largely, but perhaps not exclusively, a K^+ current.

The M-channels seem to be fully closed at membrane potentials more negative than −60 mV, as hyperpolarising commands from such potentials yielded only ohmic current steps. Above −60 mV the conductance attributable to the M-channels showed a sigmoidal increase, maximising at −10 to 20 mV (Fig. 1*c*). The position and total amplitude of the conductance–activation curve did not vary using different holding potentials between −20 and −50 mV, indicating that I_M does not show time-dependent inactivation within its activation range. The slope of the mean activation curves corresponded to an ε-fold shift in the equilibrium between open and closed M-channels for 6–7 mV depolarisation, as though the state of the channels was controlled by a tetravalent voltage-sensing particle moving through the entire membrane potential[9]. Both inward and outward M-current relaxations showed an approximately exponential time course (see Fig. 3), whose time constant diminished with hyperpolarisation from a maximal value of 150–200 ms at between −40 and −30 mV. These kinetic properties distinguish the M-current very clearly from the conventional delayed rectifier current[9]. Thus, in our bullfrog neurones, the activation threshold for the latter was about −25 to −20 mV, while the time constants for the repolarising tail-currents of the delayed rectifier were an order of magnitude faster than those for the M-current at comparable membrane potentials (see Fig. 4).

To test the effect of muscarinic receptor activation on the clamp currents we used (±)muscarine as the preferred agonist; this has minimal nicotinic activity on ganglion cells[10], thus obviating the need for nicotinic blockers. Under current-clamp (Fig. 2*a*), muscarine produced the characteristic slow depolarisation and conductance decrease previously described for other muscarinic agonists[1,4]. (In many cells muscarine also induced prolonged repetitive spike discharges following injection of current pulses.) Under voltage-clamp (Fig. 2*b*) the depolarisation was replaced by a steady inward current at depolarised membrane potentials, while the reduced conductance was manifest as a reduced current response to a hyperpolarising step-command.

Both the steady inward current and the reduced steady-state

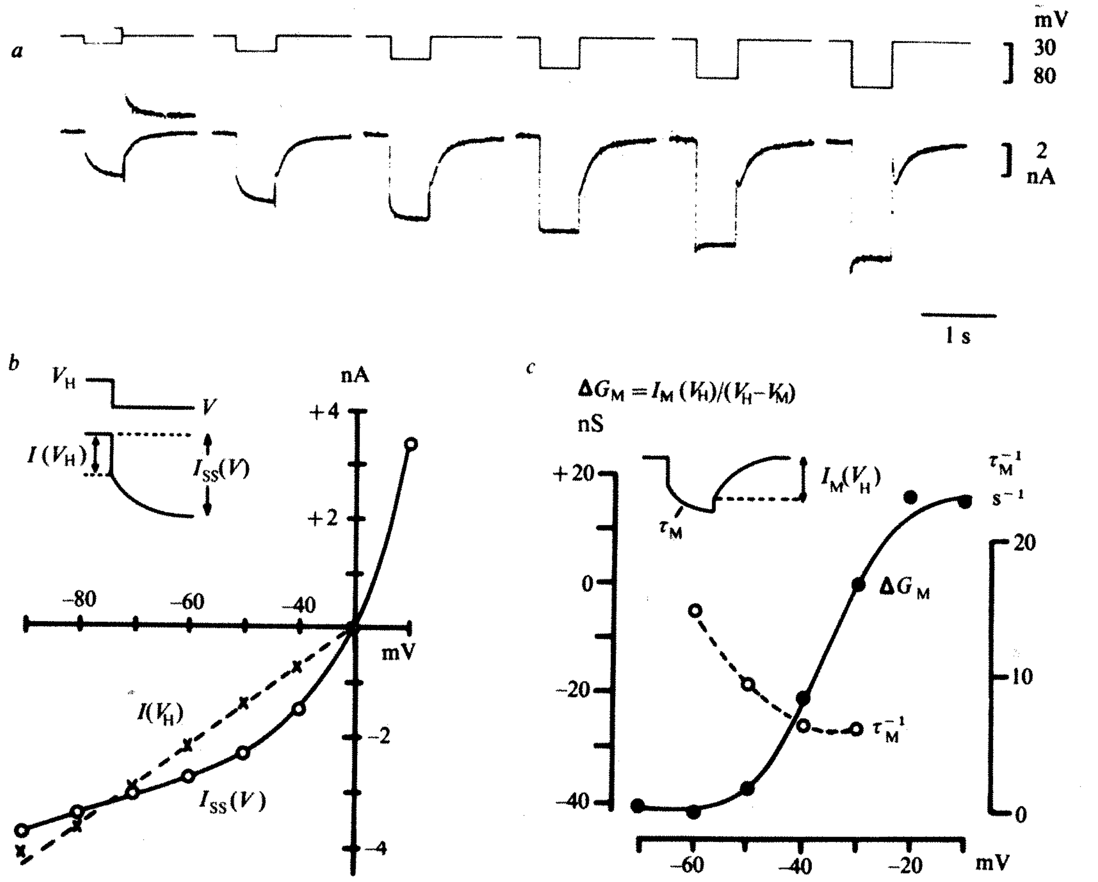

Fig. 1 M-currents in a voltage-clamped bullfrog neurone. The records in *a* show clamp-currents (bottom trace, inward current downwards) recorded during hyperpolarising step-commands from a holding potential (V_H) of -30 mV to command potentials (V) of -40 to -90 mV. The inverse current in the first panel is the slow tail of repolarising current after returning to V_H from a depolarising step-command to -20 mV. (This current record is shifted upwards for clarity; the outward current during the command is off-scale). In *b* the instantaneous (×--×) and steady-state (○——○) currents recorded in *a* are plotted against command potential (V). The instantaneous current is the amplitude of the fast transient $I(V_H)$ and the steady-state current is the total current measured after the slow relaxation is complete, $I_{SS}(V)$ (see diagram above). The intersection of the two gives the reversal potential (V_M) for the slow relaxation. The curves in *c* show the change of conductance attributable to closing and opening of the M-channels (ΔG_M, ●) and the reciprocal of the time constant of the slow relaxation (τ_M^{-1}, ○) plotted against command potential V. ΔG_M was calculated from the amplitudes of the M-current tails observed on repolarising from V to V_H (-30 mV), divided by the driving force V_H–V_M. (At $V = -20$, -10 mV only the slow component of the tail was measured, see Fig. 4*b*). τ_M Was calculated from semi-logarithmic plots of the slow inward relaxations on hyperpolarising from V_H to V (see Fig. 3 for examples). τ_M At -30 mV is the mean value for the relaxation observed on repolarising from V to $V_H = -30$, τ_M for inward and outward relaxation at the same final potential being equal.

conductance produced by muscarine result almost exclusively from a reduction of the M-current. Thus, since the M-channels would be closed at the end of the hyperpolarising command in Figure 2*b* ($V = -60$ mV, see Fig. 1*c*), the amplitude of the outward relaxation on repolarising the cell to -30 mV provides a measure of I_M at the holding potential of -30 mV. This repolarising M-current was depressed by an amount (2.2 nA) precisely equal to the magnitude of the steady inward current. Furthermore, muscarine produced negligible inward current at -60 mV. Direct proportionality between net inward current and I_M reduction throughout the potential range for I_M activation was confirmed in other experiments using different holding and command potentials. Finally, it may also be noted in Fig. 3 that the membrane conductance measured from the amplitude of the ohmic currents was greatly reduced at -30 mV but hardly at all at -60 mV.

From the time course of the M-current relaxations (Fig. 3) it appears that muscarine simply depressed the current amplitude

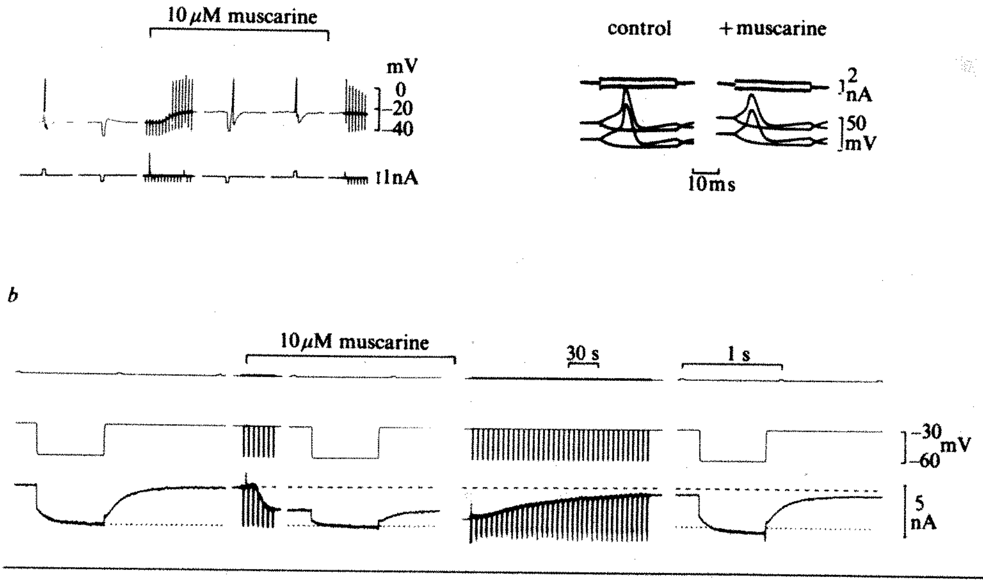

Fig. 2 Effects of muscarine on a single neurone recorded under: *a*, current-clamp, and *b*, voltage-clamp. The three traces on the chart-strip records read (from above downwards) time in s, membrane voltage, and current. The recorder was periodically accelerated to display the voltage and current transients. Muscarine was applied by rapid bath-perfusion. The oscilloscope records on the right side of the voltage response in *a* show superimposed spikes and electrotonic potentials evoked by depolarising and hyperpolarising current pulses respectively. The current pulses are on the top beam. Two voltage records are shown, the upper one being that recorded through the current-passing electrode via an active bridge circuit. In the voltage-clamp record (*b*, recorded earlier in the same cell), the membrane potential was held at -30 mV and commanded to -60 mV for 700 ms at 5-s intervals, and the induced currents recorded.

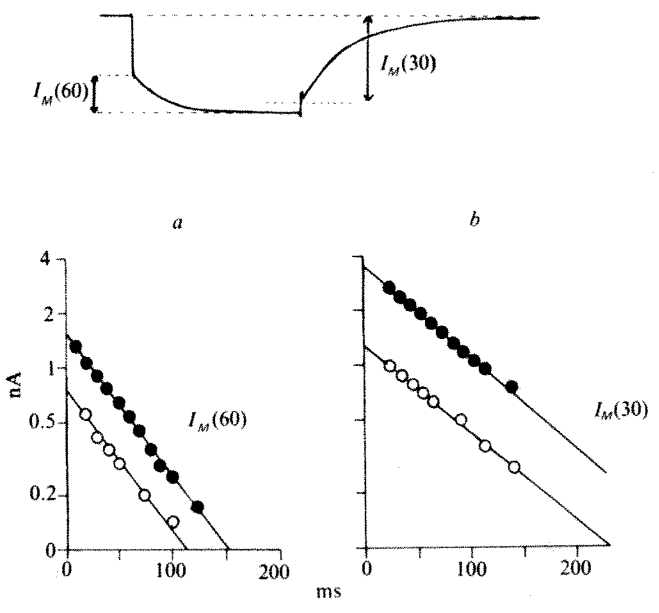

Fig. 3 Semi-logarithmic plots of the slow relaxations observed in Fig. 2*b* before (●) and during (○) muscarine application. *a*, Inward relaxation on hyperpolarising to −60 mV, I_M (60). *b*, Outward relaxation on repolarising to −30 mV, $I_M(30)$. The diagram above is a tracing of the first control current-relaxation in Fig. 2*b*, showing the measured currents.

without modifying its voltage sensitivity. Thus the ratio $\tau_M(30)/\tau_M(60)$ remained the same (1.5) in the presence and absence of muscarine. Hence any voltage sensitivity of muscarinic activation[3,11] appears to reside in the voltage dependence of the resting currents rather than in the action of muscarine *per se*. The effect of muscarine was concentration dependent, half the channels being shut at 1–3 μM, and was fully antagonised by 1 μM atropine. Varying $[Ca^{2+}]_{out}$ between 2 and 8 mM or $[Mg^{2+}]_{out}$ between 0 and 10 mM made no qualitative difference to the action of muscarine.

The unique action of muscarine on the M-current is best emphasised by comparing it with tetraethylammonium (Fig. 4): the latter profoundly depresses the delayed rectifier with little effect on the M-current, whereas muscarine suppresses I_M without depressing the delayed rectifier. (We did not see potentiation of muscarine-induced currents in 10 mM TEA solution; compare ref. 12.) The M-current was also unaffected by 1 mM Ni^{2+} which blocks inward Ca^{2+} currents in these neurones (data not shown here), or by 1–5 mM 4-aminopyridine, which inhibits the A-current of invertebrate neurones[8].

The function of the M-current is not yet clear. However, it does show some resemblance to the outward 'i_{slow}' of frog sinus tissue[13], and may likewise serve to limit firing frequency, by reducing the rate of depolarisation near the threshold for spike generation in the face of a steady or phasic inward current. The increased tendency toward repetitive spike discharges in cells treated with muscarine would accord with this: indeed, this, rather than the depolarisation itself may be the more significant feature of muscarinic excitation.

This work was supported by NIH grants NS 14920 and NS 14986. P.R.A. is a Sloane Fellow. Travel for D.A.B. was aided by a grant from the Wellcome Trust.

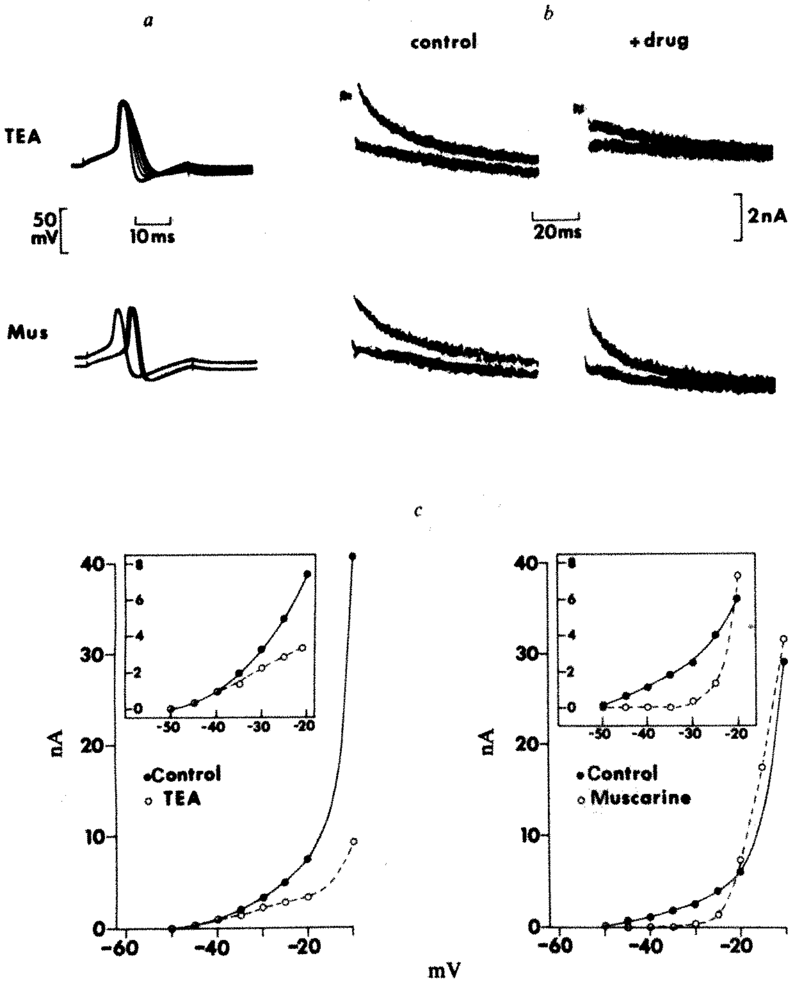

Fig. 4 Comparison of the actions of tetraethylammonium (TEA, 10 mM) and muscarine (Mus, 10μM) on *a*, unclamped action potentials, and *b* and *c*, repolarising current-tails and steady-state current–voltage curves respectively seen under voltage-clamp. The oscilloscope records in *a* show the action potentials evoked by injecting depolarising current through a single, bridge-balanced recording microelectrode, with control and drug-treated spikes superimposed. TEA prolonged spike-repolarisation without altering the membrane potential, whereas muscarine depolarised the cell without greatly affecting the spike. The records in *b* show the tail-currents seen on repolarising to the holding potential of −50 mV after depolarising commands to either −30 mV (lower trace) or −20 mV (upper trace). In the latter case, the tails showed two components, fast decaying and slow decaying, attributable to the closure of the delayed rectifier and M-channels respectively. TEA (upper records) suppressed the delayed rectifier tails; muscarine (lower records) did not affect the fast, delayed rectifier tail but reduced the amplitude of the slower M-current tail. (The apparent acceleration of the fast tail in muscarine solution is due to the loss of the slow tail.) The graphs in *c* show the steady state current–voltage curves from a single cell exposed first to TEA and then, after washing, to muscarine. The voltage-scale shows the pulse-potential from a holding potential of −50 mV. Current values (ordinates) are the steady currents attained at each pulse-potential minus the leak currents, extrapolated from the ohmic currents following step hyperpolarisations to −60 and −70 mV. The inset curves show the currents up to −20 mV on a larger scale. Note that TEA profoundly depressed the currents at membrane potentials more positive than −30 mV, whereas muscarine selectively depressed the currents below −20 mV.

Somatostatin (somatotropin release inhibiting factor, SRIF) is the 14-amino acid polypeptide found to be the active growth hormone-release inhibiting factor in extracts of sheep hypothalamus[1,2]. Although found in highest concentrations in the hypothalamus, it is widely distributed in the gastrointestinal tract and extra-hypothalamic nervous system. In fact, the cerebral cortex contains a larger total amount of somatostatin than any other brain region or visceral organ[3]. The source of somatostatin in extra-hypothalamic brain has been unclear. Initially, the hypothalamus was considered the only source, but elegant immunohistochemical demonstrations of positively staining neuronal perikarya in amygdala, hippocampus and neocortex suggested that these areas might be independent sources of somatostatin[4]. In addition, bilateral anterior hypothalamic periventricular lesions reduced somatostatin content in the median eminence to less than 10% of control levels, but did not affect its concentration in the preoptic area, amygdala or cortex[5]. Our laboratory has previously shown that dissociated rat cortical neurones in culture exhibit structural and electrophysiological properties similar to those of adult neurones *in situ*[6]. In conjunction with studies being carried out on the physiological effects of somatostatin on these neurones, we investigated the occurrence of endogeneous IR-somatostatin. We show here that dissociated cell cultures from rat cerebral hemispheres in the absence of any hypothalamic tissue produce immunoreactive (IR)-somatostatin. This IR-somatostatin is demonstrable histochemically in an exclusively neuronal population within the cultures.

Tissue was obtained by sterile removal of embryos from pregnant CD rats 15 d post-conception. The embryo skull was removed and slices were taken from antero-lateral cerebral cortex superficial to the lateral ventricles. The deeper portions of the cerebral hemisphere, including areas later giving rise to striatal structures, were discarded, as were the thalamus, hypothalamus, brainstem and cerebellum. The tissue was then minced, digested in trypsin, triturated, filtered for cell clumps, plated and grown in a medium consisting of Eagle's minimal essential medium, 5% heat-inactivated rat serum, 100 mg % glucose, 2 mM glutamine, 20 U ml^{-1} penicillin and streptomycin. The medium was changed three times per week and cells kept in a 5% CO_2 incubator at 36–37 °C. The details of the culturing procedures were as described previously[6], except that dishes in the present study were coated with collagen and polylysine instead of a layer of non-neuronal cells. Approximately 250,000 cells were initially plated in each culture dish.

For somatostatin assay, the medium (approximately 1.2 ml) was removed from the culture 3 d after the previous medium change, added to 1 ml 1 M acetic acid and frozen. The remaining cells were rinsed with physiological saline and extracted into 1.5 ml 1 M acetic acid and frozen. At the time of assay, samples were heated in boiling water, sonicated, centrifuged, lyophilised and resuspended in phosphate buffer (0.05 M with 0.1% bovine serum albumin (BSA), 0.1% sodium azide, *p*H 7.4). Radioimmunoassay was carried out with a well-characterised assay system[3].

No IR-somatostatin was detected in the initial cell suspension, in control media samples or in early cultures, but was detected in both cell extracts and media by day 7 of incubation (Fig. 1). Between 7 and 14 d the content in the cellular fraction increased dramatically. Concentrations of IR-somatostatin increased steadily to a maximum at approximately 3 weeks when the cellular fraction contained an average 3,033 ± 7.5 pg per dish and the media contained 326 ± 75.8 pg per ml media. The slightly decreased levels at points around 4 weeks in culture were thought to correspond to declining neuronal survival.

Chromatographic characteristics of the IR-somatostatin of both the cell extracts and the media were determined using a Biogel P-4 column with an ammonium acetate buffer (*p*H 4.7). The IR-somatostatin from both the cell extracts and the media eluted identically with the synthetic cyclic somatostatin standard. In addition, 8% of the IR-somatostatin in the cell extract migrated more slowly in a separate peak corresponding to a larger form of IR-somatostatin.

Immunofluorescent staining was carried out on cells cultured for 17–33 d on collagen–polylysine-covered glass coverslips. The coverslips were rinsed in a phosphate-buffered saline (PBS) and fixed in 3% formaldehyde in PBS and finally in cold acetone. The acetone step was added to increase the permeability of the fixed cell membranes and resulted in a marked increase in specific immunofluorescence over that obtained with formaldehyde alone, but with preservation of cellular morphology.

After fixation, a rabbit antibody prepared against BSA-conjugated somatostatin was applied at a 1:200 dilution with

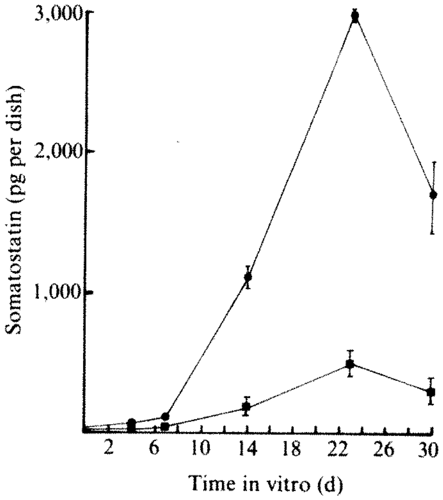

Fig. 1 Graph of IR-somatostatin in cell fraction (●) and in media fraction (■) per 35-mm dish containing dissociated cell culture of rat embryo cerebrum against days *in vitro* (mean ± 1 s.d. for determinations on three cultures). Total volume of cells is very small (<0.1 cm^3 per dish) compared with the volume of media (~1.2 cm^3 per dish), which emphasises the greater amount concentrated in cells. Levels of IR-somatostatin are undetectable until approximately day 7. Between days 7 and 23 the levels increase dramatically. The late fall-off probably indicates some deterioration in the cultures rather than a specific decline in somatostatin production.

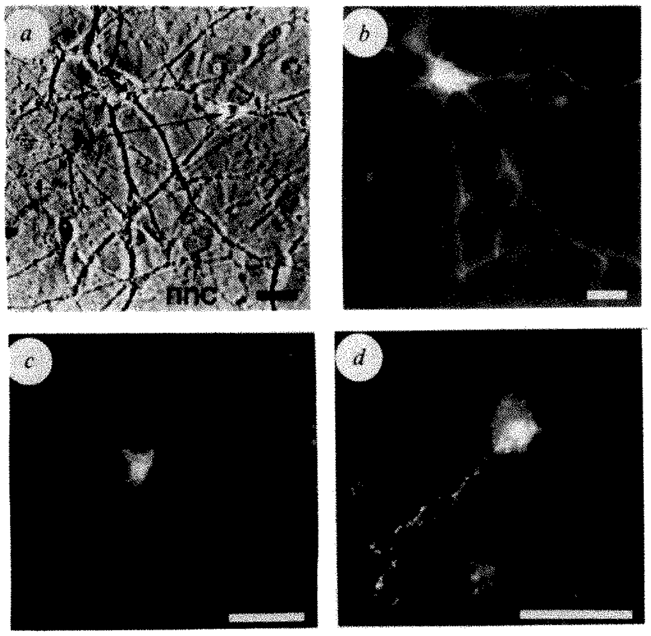

Fig. 2 Phase-contrast and indirect immunofluorescent microscopy of neurones in the dissociated cell cultures. *a*, Dispersed cerebral cell culture at 32 d seen under phase-contrast microscopy. Note flat non-neuronal cells (nnc) as well as neurone cell bodies (N) and neuronal processes. *b*, *c*, *d*, Fluorescence photomicrographs showing cultures stained with anti-somatostatin using indirect immunofluorescent technique. *b*, Same field as *a*, showing positive staining of the perikaryon and its neuronal processes. Note the selective staining of this neurone as distinguished from the several unstained neurone cell bodies and many unstained neuronal processes, prominently seen in *a* by phase contrast. *c*, Pyramidal-shaped neurone positively stained by anti-somatostatin in the presence of more dimly seen negatively staining neurones of roughly the same size in culture at 18 d. Staining in perikaryon of neurones often seemed to be continuous with staining in the proximal part of cell processes. *d*, Neurone positively stained by anti-somatostatin with smaller collections of staining trailing out a neuronal process in an 18-d culture. Scale bars, 25 μm.

incubation at 37 °C for 1 h. Next, fluorescein-conjugated goat anti-rabbit IgG (Meloy Laboratories) was applied at a 1:35 dilution with incubation at 37 °C for 1 h. Coverslips were mounted in glycerol at *p*H 8.5, and viewed and photographed under a Zeiss fluorescence and phase-contrast microscope. Specificity was demonstrated by absence of specific staining when the rabbit anti-somatostatin at 1:100 dilution was adsorbed with an equal volume of 10^{-3} M somatostatin before use. Staining was unaffected by adsorption with gonadotropin releasing hormone, vasopressin or ACTH.

Dichter has previously reported that by using a variety of confirmatory techniques (including silver staining and intracellular recordings), neurones can be recognised in the cultures by their appearance under phase-contrast[6]. All the cells shown by the indirect immunofluorescent technique to contain IR-somatostatin in these cultures were morphologically indistinguishable from neurones identified by these other criteria.

An estimated 3–5% of the neuronal population stained unequivocally in each culture. Most somatostatin-positive cells had two or more large dendritic processes, but by phase-contrast microscopy these positively staining cells could not be distinguished from non-somatostatin-containing neurones. Within cell bodies, IR-somatostatin was predominantly located in a perinuclear distribution which often seemed continuous with staining in the proximal portions of cell processes (see Fig. 2). In axonal processes the staining was most frequently seen in varicosites, and a densely stained collection was often seen at the most distal portion of the process.

These results suggest that neurones of the mammalian cerebral hemispheres can produce somatostatin completely independently of the hypothalamus. The finding of a larger form of IR-somatostatin corresponds with similar findings in many other nervous and gastrointestinal tissue homogenates, including extra-hypothalamic brain[3,7]. The presence of this larger form in the cellular fraction, and not in the media, suggests a prohormone which is not secreted as such, but pulse-chase studies must be made before the presence of such a precursor can be confirmed.

Many studies have reported neurophysiological effects of somatostatin; it depresses the firing of neurones in hypothalamus, cerebellar cortex and cerebral cortex[8], and in brainstem, reticular formation and dorsal hippocampus[9]. By contrast, somatostatin has been shown to excite cortical neurones in conscious rabbits[10] and in a rat hippocampal slice preparation[11]. Its release by calcium-dependent depolarisation has been demonstrated in several neural structures, including hypothalamus[12,13], neurohypophysis[14] and dorsal root ganglia[15]. Our findings support the view that somatostatin may have a role as an extra-hypothalamic central nervous system neurotransmitter or neuromodulator.

We thank Bernard Biales and Sara Vasquez for help with the tissue cultures, Bonnie Asch for guidance in developing the immunohistochemical techniques, and Judy Bollinger for assistance with the radioimmunoassay and chromatography.

Cholesterol levels inversely reflect the thermal sensitivity of mammalian cells in culture

Anne E. Cress & Eugene W. Gerner

The University of Arizona Health Science Center, Departments of Biochemistry and Radiology/Radiation Oncology Division, Tucson, Arizona 85724

Cholesterol is a primary component of the mammalian cell plasma membrane. Although its function is unknown, it may be of major importance in maintaining membrane fluidity and rigidity[1]. In artificial membrane systems, the addition of cholesterol results in a condensing effect—thickening the bilayer and inducing higher order in the acyl chains of the phospholipids[2]. Permeability profiles indicate that the addition of cholesterol into egg-lecithin bilayers increases the half-time of solute transport[3]. In addition, decreased amounts of sterol in the membrane increase glucose permeability, and, in L cells, increase the transport of rubidium[4,5]. These studies suggest a role for cholesterol in changing the physical characteristics of the membrane resulting in the alteration of membrane permeability. We now provide evidence that cholesterol may act, presumably via changes in physical membrane properties, with yet another biological consequence; regulating the survival sensitivity of mammalian cells to hyperthermic temperatures.

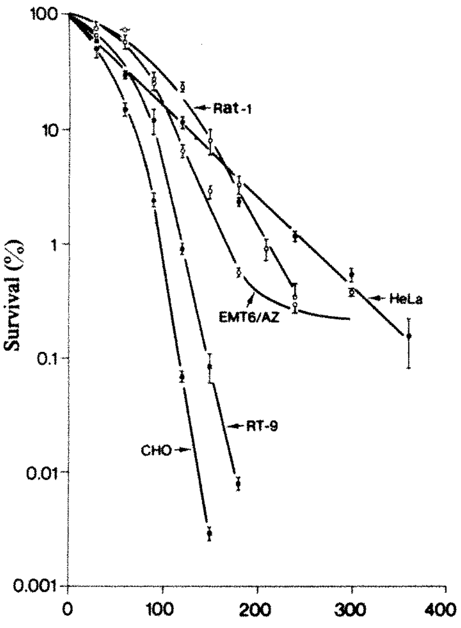

Fig. 1 Thermal survival response of exponentially growing cells in culture. (●), HeLa; (○), EMT6/AZ; (■), RT-9; (□), Rat-1; (×), CHO. After exposure of the cells to 43 °C for the indicated times, cells were collected and plated for colony formation. Standard errors of survival determinations are shown.

Elevated temperatures are known to result in the modification of physical membrane properties in prokaryotic cells, principally by alteration of the amounts of saturated and unsaturated fatty acids[6]. Yatvin[7] has shown that dietary manipulation of the proportion of saturated and unsaturated fatty acids in *Escherichia coli* membranes acts to modify the thermal sensitivity of these organisms. Prokaryotic membranes contain essentially no sterol and the membrane composition in general is quite different from eukaryotes[8]. However, the physical changes of the prokaryotic membrane during the acclimation to elevated temperatures are remarkably similar to the changes in the mammalian cell membrane when cholesterol is introduced. In both cases, the membranes become more ordered and less permeable.

We have previously shown that one immediate response to exposure to elevated temperatures is an increase in plasma membrane permeability[9]. Recently, we have demonstrated that modification of membrane permeability can also lead to modification of cellular viability at hyperthermic temperatures[10].

Guided by these observations, we added whether the known different heat sensitivites of various mammalian cell lines in culture[11] would reflect differences in the amount of cholesterol in the unheated cells. One would expect that elevated levels of cholesterol in untreated cells might be expressed as a higher survival rate following hyperthermia treatments. Hyperthermia in this study represents an elevation of temperature from 37 °C to 43 °C.

Cultures of HeLa, EMT6/AZ, Rat-1, RT-9, and CHO cell lines (see Table 1 for identification of cells lines) were maintained and treated in log phase growth in McCoy's 5A medium supplemented with 20% fetal calf serum, 100 units ml^{-1} penicillin and 100 μg ml^{-1} streptomycin (all from GIBCO). All lines were grown in a 5% CO$_2$–95% air atmosphere at 37 °C. Doubling times, under these conditions for the HeLa, EMT6/AZ, Rat-1, RT-9, and CHO cells, were 20–22, 15–16, 15–17, 14–15, and 13–15 h, respectively. Colony-forming efficiencies for untreated cells growing at 37 °C, for these same lines were 60–80%, 60–80%, 50–70%, 60–80%, and 80–95% respectively.

Cell survival, determined by the colony-forming ability of single cells, was used as the index of the thermal sensitivity of the various cell lines studied. The procedure we used, and the hyperthermic treatment conditions in our temperature-controlled water bath (temperature uniform and constant to ±0.1 °C), have previously been described in detail[12,13].

For cholesterol determination, 2.5×10^7 cells per sample were collected by scraping with a 'rubber policeman', washed in Puck's saline A (GIBCO), and sonicated into 0.01 M Tris buffer, *p*H 7.2 and centrifuged for 20 min. at 20,000 r.p.m. The particulate fraction was extracted with chloroform : methanol : water (2 : 2 : 1) and the amount of cholesterol determined spectrophotometrically by the method of Glick *et al.*[14]. Cholesterol (Sigma) was used as the standard and the extraction procedure was checked by thin layer chromatography using a chloroform : methanol : acetic acid (90 : 10 : 1) solvent. Protein determinations were done according to the Bradford method[15]. Phospholipid concentrations were measured from the extract of the particulate fraction by the colorimetric method of Raheja *et al.*[16]. A chromatographically pure reference standard of phosphatidyl choline (Sigma) was used.

The molar ratios of saturated to unsaturated fatty acid represents 18 : 0/18 : 1. Approximately 1.0×10^6 cells were used for this particular assay. After the particulate fraction was isolated (as previously described) 1 ml of 2.5 M KOH in methanol and 40 μg of heptadecanoic acid (an internal standard) were added and this mixture was heated for 30 min at 70 °C. After cooling, 1.5 ml of 1 M phosphoric acid was added and mixed well. Then 1 ml of hexane was added to the hydrolysate, mixed well, and centrifuged at 3,000 r.p.m. for 3 min. Two additional 0.5 ml hexane extractions were carried out and all the hexane solutions were combined. To the hexane solution, 200 μl of 0.5 M aqueous trimethyltrifluorotolylammonium hydroxide[17] were added. Fatty acid methylesters were formed on the gas chromatograpic column (2 mm × 0.5 M, 3% Silar 10C on Gas Chrom Q 100/120) which was interfaced with a mass spectrometer (Finnigan 3300). The fatty acid methylesters were quantified by their relative weight response to the internal standard using the total ion current of the selected ions.

Figure 1 shows the per cent survival of each cell line as a function of time at 43 °C. Note that all cell lines were grown in identical medium since it is known that exogenous cholesterol affects the cellular biosynthesis of the sterol[18]. Under these conditions, cellular sensitivity to a heat challenge is different for each cell line studied. HeLa cells appear to be the most thermal resistant cell line and CHO the most thermal sensitive of the lines tested. Also, most lines display a non-exponential survival response ('shoulder region') which precedes the exponential decrease in cell survival as time at 43 °C increases. The HeLa cells are an exception to this case, while the EMT6/AZ cells deviate from strictly exponential cell killing at longer treatment times. The plateau in the survival response for EMT6/AZ cells, after 200 min of hyperthermic exposure, represents the development of heat resistance and has been studied in detail for this line[19].

Comparisons of the differences in thermal sensitivity between these lines can be made by determining the D_0, a common

Table 1 Cholesterol content in the particulate fraction of untreated cells growing at 37 °C and the sensitivity of these cells to 43 °C

Cell line	Source	Cholesterol (μg per mg protein)	D_0 (43 °C) (min)
HeLa	Human cervix carcinoma	54.06 ± 1.50	54
Rat-1	Rat embryo fibroblast	33.90 ± 0.15	28
EMT6/AZ	Mouse mammary sarcoma	33.74 ± 0.98	24
RT-9	Rat astrocytoma	20.66 ± 2.86	12
CHO	Chinese hamster ovary	18.63 ± 0.41	10

parameter in the radiobiological literature, for each survival response. The D_0 value is simply the reciprocal slope of the exponential portion of the survival curve, and in this case, has units of time for a specific temperature. Thus, a survival curve with a higher D_0 than that of another indicates relative resistance to the particular treatment.

Table 1 lists the sources of the cell lines tested, the respective D_0 value for each cell line, which was calculated from Fig. 1, and the amount of cholesterol found in untreated cells. The quantity of cholesterol is expressed in terms of protein amounts found in the cell particulate fraction. There appears to be a remarkable correlation between D_0 and the cholesterol content. This correlation is still valid when the cholesterol content is related to cell number (data not shown). Since D_0 is inversely related to the survival sensitivity of treated cells, these data show that cholesterol content is inversely correlated with hyperthermic sensitivity. In addition, we investigated whether D_0 would also correlate with the cholesterol-to-phospholipid molar ratio or the degree of saturated to unsaturated fatty acid found in the particulate fractions of the cell lines under study. This is important since these various membrane parameters are also known to affect the physical state of the membrane and might just as easily correlate with the respective D_0 value. Table 2 gives the cholesterol-to-phospholipid molar ratio and the molar ratio of 18:0 to 18:1 observed in four of the nine cell lines tested. It is important to note that the ratio of saturated to unsaturated fatty acids does not follow any significant pattern with the amount of cholesterol present in each cell line. Our interpretation is that the best correlate with the survival response to hyperthermia (D_0) is still the amount of cholesterol in the particulate fraction.

Table 2 Relationship between heat sensitivity at 43 °C, cholesterol : phospholipid molar ratio, and the ratio of saturated to unsaturated fatty acid (18 : 0/18 : 1)

Cell line	Heat sensitivity at 43 °C (D_0) (min)	Cholesterol : phospholipid molar ratio	Saturated: unsaturated fatty acid molar ratio
Rat-1	28	0.264	1.4
EMT6/AZ	24	0.657	0.86
RT-9	12	0.470	1.0
CHO	10	0.502	1.4

As described in Fig. 2, this correlation is expressed as a nearly linear relationship between the respective D_0 value for each cell line and the measurable cholesterol present in the cell particulate fraction. This linear relationship is impressive, since the thermal survival sensitivity does not correlate with any other obvious parameters of the lines tested, such as species, doubling time or colony-forming abilities, as mentioned earlier, of the untreated cells. Nor does survival sensitivity correlate directly with the tumorogenicity of the cell lines tested, since the Rat-1 and CHO cell lines are of normal tissue origins, while the HeLa, RT-9, and EMT6/AZ cell lines are of tumour origins. The RT-9 and EMT6/AZ cell lines are normally maintained by sequential *in vivo*/*in vitro* passage and form solid tumours when grown in F344 rats and BALB/c mice, respectively. It should be noted here that Green estimates that 95% of the cellular cholesterol is located in the plasma membrane[20]. Therefore, it is reasonable to presume that the cholesterol content measured here represents plasma membrane cholesterol.

The demonstration of increased cholesterol content in cells that are relatively resistant to elevated temperatures (HeLa compared to CHO) is interesting because it suggests that the sterol provides a similar function to the saturation of fatty acids in prokaryotes. In addition, since hyperthermia is presently used as an anticancer agent, this finding offers the possibility of a predictive tool for determining individual tumour susceptibility to subsequent hyperthermia therapy.

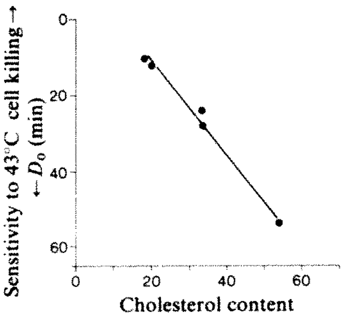

Fig. 2 Relationship between cholesterol content in untreated cells and 43 °C survival sensitivity. The values for the respective D_0 and cholesterol content of each cell line were taken from Table 1. This emphasises in graphical form the apparent linear relationship between cellular sensitivity to 43 °C and the cholesterol content in untreated cells.

In either case, it is important to test further the correlation of cholesterol, and other factors affecting membrane structure and permeability, and heat resistance. In this regard, it is of interest that the cholesterol : phospholipid molar ratios and the saturated : unsaturated fatty acid molar ratios do not correlate with various heat sensitivities of the cell lines tested. Studies to be published elsewhere do, however, show that the saturated : unsaturated fatty acid molar ratio does correlate with cell survival sensitivity at 43 °C, within one cell line, when the normal growth temperature is either increased or decreased from 37 °C. These studies emphasise that a number of factors affecting membrane structure and function may be involved in cellular responses to hyperthermia and that the normal growth temperature may be important in determining which of these factors are limiting. We are also extending the studies in this report by asking if cholesterol content is also elevated under conditions of induced thermal resistance[12]. Preliminary experiments demonstrate that this is the case[10], which in turn suggests that the activity of HMG-CoA reductase, the rate-limiting enzyme in cholesterol biosynthesis, should also be increased in thermal-resistant cells.

We thank Mr Patrick S. Culver for technical assistance and Dr Sai Y. Chang for saturated and unsaturated fatty acid measurements. This research was supported by USPHS grants CA-18273, CA-17343, and GM-07239.

The position of tropomyosin in muscle thin filaments

J. Seymour & E. J. O'Brien

Medical Research Council Cell Biophysics Unit, Department of
Biophysics, King's College, 26–29 Drury Lane, London WC2, UK

The contraction of vertebrate skeletal muscle is controlled by the action of Ca^{2+} on muscle thin filaments. At low Ca^{2+} concentrations ($<10^{-6}$ M) the regulatory proteins of the thin filament, tropomyosin and troponin, relax muscle by preventing the interaction of myosin and actin. At higher Ca^{2+} levels this inhibition is removed, when Ca^{2+} binds to troponin. Tropomyosin, a long coiled-coil α-helical molecule, is located in each of the two long-pitch helical grooves of actin, but troponin, a globular molecule, is attached at intervals of 38 nm (refs 1, 2). By combining evidence from X-ray diffraction studies of muscle and from electron microscopy, several authors have proposed that tropomyosin moves to block or allow attachment of myosin heads to actin[3–5]. We investigate here an alternative way of combining the data, which if valid may have important consequences for our understanding of the regulation of muscle contraction[6].

Figure 1 illustrates the problem. The shape and attachment site of myosin subfragment-1 (S-1) are based on a three-dimensional reconstruction of electron micrographs of the S-1–thin filament complex calculated by Moore *et al.*[7]. This reconstruction does not have sufficient resolution to reveal tropomyosin, but its position may be derived from analysis of X-ray diffraction patterns of muscle[3–5], or image analysis of electron micrographs of reconstituted thin filaments[8,9]. However, as pointed out by previous authors[3,8], these studies have not shown on which side of the actin groove tropomyosin is located relative to the S-1 attachment site. To remove this ambiguity, it is necessary to superimpose, with the correct relative orientation, reconstructions of decorated and undecorated thin filaments, the latter showing tropomyosin well resolved. If reconstructions are carried out on micrographs of I-segments, the assemblies of thin filaments still attached to the Z-line, the correct orientation is known, because the characteristic arrowhead appearance obtained by adding S-1 to thin filaments always points away from the Z-line[10].

An I-segment from a crude muscle homogenate obtained at a low Ca^{2+} concentration is shown in Fig. 2*a*. Some homogenates at a high Ca^{2+} level were studied, but acto-myosin precipitation made these experiments difficult. At low Ca^{2+} concentrations, all preparations produced up to 80% inhibition of the acto-myosin ATPase rate, confirming the presence of regulatory proteins. Furthermore, troponin gave rise to strong meridional reflections at 1/38.5 nm^{-1} in the Fourier transforms of many micrographs and also gave rise to corresponding periodic stripes visible in large I-segments. Side-by-side aggregation of filaments into paracrystals was induced by raising the Mg^{2+} concentration, but single-layered paracrystals of more than two or three filaments were rare because movement of the filaments was restricted by their Z-line attachment and tangling readily occurred. Filaments within paracrystals are usually better for image analysis studies because they are straighter, more evenly stained and less flattened[11].

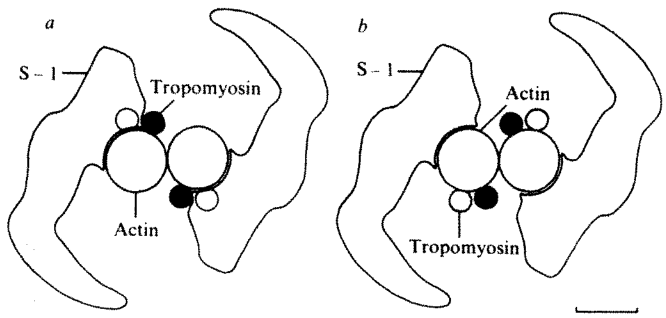

Fig. 1 The two ways of superimposing reconstructions from decorated (that is, complexed with S-1) and undecorated thin filaments. *a*, Based on Huxley[3]. *b*, As *a* except that the thin filament has the opposite orientation. The arrowheads are pointing out of the plane of the paper away from the Z-line. Tropomyosin in contracting muscle is represented by filled circles and in relaxed muscle by open circles. Scale bar, 5 nm.

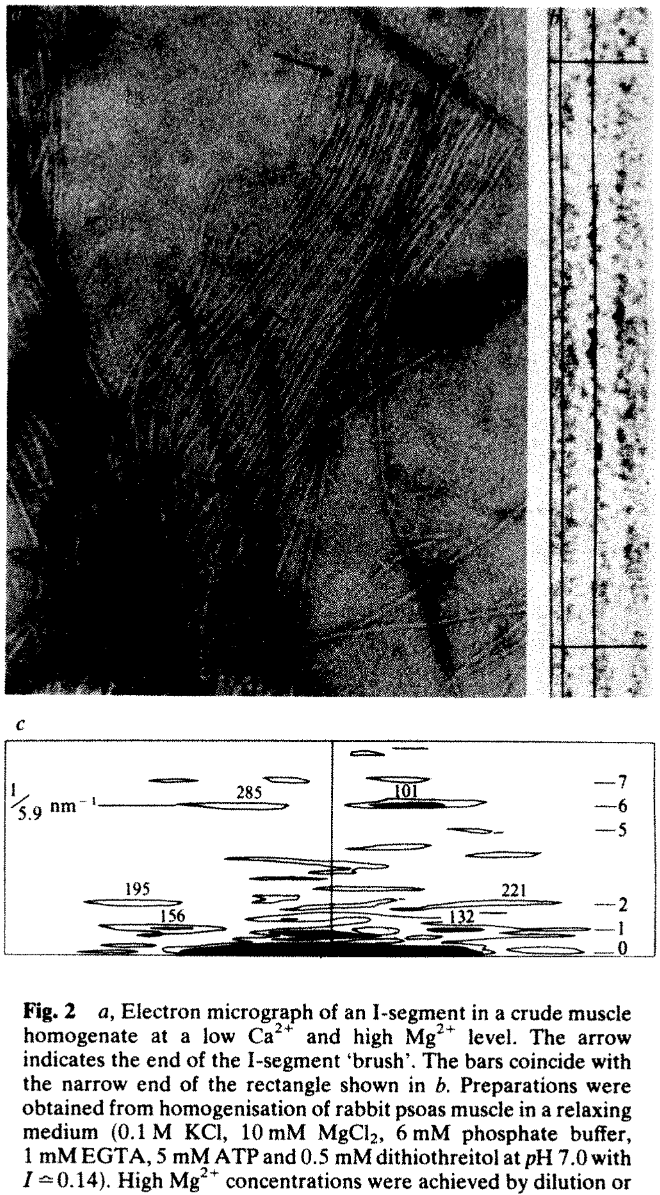

Fig. 2 *a*, Electron micrograph of an I-segment in a crude muscle homogenate at a low Ca^{2+} and high Mg^{2+} level. The arrow indicates the end of the I-segment 'brush'. The bars coincide with the narrow end of the rectangle shown in *b*. Preparations were obtained from homogenisation of rabbit psoas muscle in a relaxing medium (0.1 M KCl, 10 mM $MgCl_2$, 6 mM phosphate buffer, 1 mM EGTA, 5 mM ATP and 0.5 mM dithiothreitol at *p*H 7.0 with $I \simeq 0.14$). High Mg^{2+} concentrations were achieved by dilution or dialysis into the above relaxing medium, except KCl was replaced by $MgCl_2$ to give an overall $I \simeq 0.15$. Some preparations were diluted or dialysed into a high Ca^{2+} concentration medium (0.1 M KCl, 6 mM $MgCl_2$, 4 mM ATP, 2 mM $CaCl_2$ and 10 mM ImCl at *p*H 7.3 and $I \simeq 0.13$). Specimens were mounted on carbon-coated copper grids and negatively stained with 1% uranyl acetate. Magnification ×88,000. *b*, Display of densitometered region of *a*. The marked rectangle encloses the area Fourier transformed in *c*. *c*, Fourier transform of single filament shown in *b*. Amplitude peaks are contoured and numbers above layer-line peaks indicate phases. Layer-line numbers shown on right hand side are those arising from an actin filament with 13 subunits in 6 turns of the genetic helix[7].

0028-0836/80/070680—03$01.00

Only filaments that seemed to be connected to a Z-line and terminated at the end of the I-segment 'brush' were considered for analysis. Optical diffraction patterns of electron micrographs of many hundreds of such filaments were examined, but only 20 patterns clearly showed at least three actin layer lines. The density distribution of these micrographs was converted into digital form and their Fourier transforms calculated[11] (Fig. 2*b*, *c*). The quality of the phase and amplitude information justified three-dimensional reconstruction in eight cases, where for example, the phase residual was always less than 37° and had an average value of 28°. The phase residual (see Table 1) is a measure of the amount by which the helical symmetry deviates from that expected for actin[7], and was calculated for all non-equatorial layer-line data of medium or strong intensity. A high phase residual was associated with asymmetries between the upper and lower sides of the filaments and the relatively poor signal:noise ratio, arising from additional proteins in the homogenate and filament curvature restricting the length of filaments processed. Straight filaments not in paracrystals sometimes gave low phase residuals, but in most cases it was better to mask off a filament within a paracrystal or to deconvolute the Fourier transform of the paracrystal to give the transform of an average filament. Six reconstructions clearly resolved the relative positions of actin and tropomyosin, in one case the Ca^{2+} level was high. By orientating each reconstruction with respect to the Z-line, tropomyosin was consistently found to occupy positions shown in Fig. 1*b*, that is, on the opposite side of the actin groove to that of the postulated S-1 binding site.

Two reconstructions can be calculated from any set of Fourier transform data, using layer-line information arising from either the upper or lower sides of the filament[12]. In Table 1 the discrepancies between the peak amplitudes measured on the left and right hand sides of the meridian and the sometimes large value of $(\Delta\theta \mp \pi n)$ indicate a difference in the stain distribution on the two sides of the filament. The data corresponding to each side were therefore used independently to calculate three-dimensional reconstructions, and in each case the assignment of the actin and tropomyosin positions was the same. Additionally, model calculations indicated that phase changes on the first and second layer lines of two to three times the average phase residual would be required to move the tropomyosin from one side of the actin groove to the other.

Table 1 Peak amplitude and phase data

Filament reference no.	Actin layer-line no.[7]	Peak amplitudes (arbitrary scale, not normalised)		$\Delta\theta$ $\mp\pi n$	Phase residual
		LHS	RHS		
	1	115	217	36°	
1	2	108	52	32°	28°
	6	172	165	9°	
	1	164	245	4°	
2	2	76	151	28°	20°
	6	172	137	1°	
	1	143	162	4°	
3	2	85	125	88°	25°
	6	117	141	8°	
	1	129	201	14°	
4	2	83	94	11°	37°
	6	141	147	27°	
	1	187	167	18°	
5	2	119	127	29°	24°
	6	203	118	11°	
	1	98	96	56°	
6	2	75	79	1°	31°
	6	73	124	46°	

The data for filament 2 were obtained from the deconvoluted Fourier transform of a paracrystal. In other cases, the data shown are from the transform of masked-off filaments. For filaments 4 and 5, the deconvolution analysis was also carried out and gave results not significantly different from those shown. $\Delta\theta$ Is the phase difference between Fourier coefficients along a layer line on opposite sides of the meridian and at a radial spacing equal to the average radial spacing of the peak amplitude on each side of the meridian. n Is the principal Bessel order expected on the layer line in question. The phase residual is normalised, amplitude weighted $(\Delta\theta \pm \pi n)$ using all Fourier coefficients whose amplitudes are significantly above the background noise level, as described by Wakabayashi *et al.*[8] (where it is termed a 'self residual' Q). The full amplitude contour map for filament 5 is shown in Fig. 2*c*.

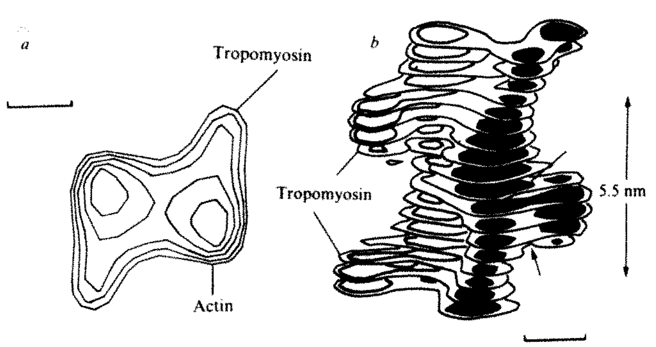

Fig. 3 *a*, Contour map of the helical projection derived from averaged layer-line data. The helical projection is formed by projecting the structure down the long-pitch (72 nm) actin helices looking towards the Z-line. *b*, Three-dimensional reconstruction from averaged layer-line data, with the Z-line at the bottom. The different shadings indicate the long-pitch actin and tropomyosin strands on opposite sides of the helical axis. Actin layer lines[7] used in these reconstructions included $l = 0, 1, 2, 3, 5, 6, 7$ and 8. The equator was used at full weight and meridional reflections on the first layer line were weighted down[8]. Data were derived from three transforms originating from filaments at low Ca^{2+} concentrations. Scale bars, 2 nm.

Five sets of data from three filaments (2, 3 and 5 of Table 1) were averaged by the methods of Amos and Klug[13], and Fig. 3*a* shows the resulting helical projection. The averaging produced an improvement in the signal:noise ratio of the data, particularly on weaker layer lines. Great care was taken to preserve the known orientation of each filament and the effect of each mathematical operation was monitored on a test object, which was an S-1-decorated thin filament having an obvious polarity. The helical projection shows on each side a well resolved actin peak with, extending to higher radius, a smaller region of lower density attributable to tropomyosin. This assignment is confirmed by the three-dimensional analysis (Fig. 3*b*), where the size and shape of the actin subunit are consistent with that observed in other reconstructions[8]. In common with earlier reconstructions[14], tropomyosin seems to be discontinuous, which may be due to inadequate resolution and the periodic merging of tropomyosin with part of the actin subunit. Where tropomyosin diverges from one end of the actin subunit a V-shaped cleft is formed (arrow, Fig. 3*b*). Furthermore, each actin subunit makes a connection to each of the two adjacent subunits in the other long-pitch strand and these are asymmetrically disposed with respect to the subunit's centre of mass. These features are present in the reconstructions of Wakabayashi *et al.*[8] and assist in assigning filament polarity.

These reconstructions remove an important ambiguity present in all previous structural work as to which side of the actin groove tropomyosin occupies. It is not known whether the azimuthal movement of tropomyosin regulates contraction by sterically blocking incoming myosin heads, or by changing the conformation of actin subunits so that they cannot bind myosin. The steric blocking model was formulated on the assumption that tropomyosin occupies positions shown in Fig. 1*a*, which we have found to be erroneous. In Fig. 1*b* there is no obvious way in which tropomyosin can sterically block myosin, unless the shape of S-1 or its position of attachment to actin is revised. We understand that K. Taylor and L. A. Amos (personal communication) are now re-examining the structure of decorated thin filaments and their results will be of particular interest.

We thank J. Trinick for assistance with the initial I-segment preparations and G. Offer, P. M. Bennett and M. J. Dickens for their criticisms of the manuscript. J.S. acknowledges a research studentship from the SRC.

Electron transfer reagent binding sites on plastocyanin

David J. Cookson, Mark T. Hayes & Peter E. Wright

Department of Inorganic Chemistry, University of Sydney, Sydney, NSW 2006, Australia

Electron transfer is an essential process in all biological systems. The kinetics of electron transfer reactions between small inorganic complexes and a variety of metalloproteins have been extensively studied[1–5]. Recent studies on the electron transfer reactions of plastocyanin, an essential component of the photosynthetic electron transport chain, have shown[6–9] that inorganic redox reagents such as the hexacyanoferrate(III) ion ($Fe(CN)_6^{3-}$) and the tris(1,10-phenanthroline)cobalt(III) ion ($Co(1,10\text{-phen})_3^{3+}$) form discrete complexes with the protein before the electron transfer step. Here, we have used high resolution nuclear magnetic resonance spectroscopy (NMR) to study the interaction of plastocyanins from French bean (*Phaseolus vulgaris*) and cucumber (*Cucumis sativus*) with the chromium(III) analogues of these redox reagents, $K_3Cr(CN)_6$ and $Cr(1,10\text{-phen})_3(ClO_4)_3$. The binding of these complexes to plastocyanin is highly specific and we identify two binding sites, separated by about 15 Å, which are apparently determined primarily by electrostatic interactions. Two distinct electron transfer pathways to and from the copper atom are indicated.

Plastocyanin is a type 1 or 'blue' copper protein of molecular weight 10,500. It contains one copper atom, in a distorted tetrahedral environment, which is coordinated by the thiol group of Cys 84, the thioether group of Met 92 and the imidazole groups of His 37 and His 87 (ref. 10). Its low molecular weight makes it ideally suited to study by high resolution NMR spectroscopy and to date the resonances of many amino acids near the copper atom have been identified[11–14]. These resonances, which are readily detected in the spectrum of the copper(I) protein, are broadened beyond detection when the protein is in the copper(II) state. The aromatic region of the proton NMR spectrum of reduced French bean plastocyanin is shown in Fig. 1*a*. The resonances of both histidine residues, all three tyrosine and two phenylalanine residues have been identified previously[13]. With the help of the X-ray crystal structure[10], assignments to specific amino acids can now be made. Full details will be published separately but we note here that coupled doublets at 6.51 and 6.64 p.p.m., which arise from the tyrosine residue closest to the copper atom[13], can, from the X-ray structure[10], be assigned to Tyr 83. Specific assignments of the histidine resonances have also been made. On the basis of their pronounced *p*H dependence (ref. 11 and our own unpublished observations), resonances at 7.66 and 6.97 p.p.m. are assigned to the C-2 and C-4 protons[13], respectively, of His 87 which is exposed to the solvent at one end of the molecule[10]. The other, more deeply buried histidine (His 37) must thus give rise to the resonances[13] at 7.57 and 7.16 p.p.m. which show only slight dependence on *p*H. The spectrum of the French bean protein has many features in common with those of other plastocyanins and the protein structure, particularly in the vicinity of the copper atom, is expected to be conserved in plastocyanins from all higher plant species[13].

The effect of addition of $Cr(CN)_6^{3-}$ to a solution of reduced French bean plastocyanin is shown in Fig. 1*b*. Significant changes in the NMR spectrum occur and are best seen in the difference spectrum shown in Fig. 1*c*. At low concentrations of $Cr(CN)_6^{3-}$, the resonances of His 87 broaden. As the concentration of $Cr(CN)_6^{3-}$ is increased, the resonances of His 37 also begin to broaden. In the aliphatic region of the spectrum (not shown), the resonance of Met 92 (a copper ligand) at 0.57 p.p.m. is broadened slightly.

Perturbations are also observed in the NMR spectrum of reduced plastocyanin when the protein is titrated with $Cr(1,10\text{-phen})_3^{3+}$ (Fig. 2). However, these perturbations differ from those observed with $Cr(CN)_6^{3-}$. The resonances of Tyr 83 are broadened dramatically, the effect being most noticeable at a $Cr(1,10\text{-phen})_3^{3+}$ concentration of 0.4 mM (3.5 mM plastocyanin). In the aliphatic region of the spectrum, the methyl group proton resonances of two or three (as yet unidentified) amino acid residues are broadened. These resonances are not broadened by $Cr(CN)_6^{3-}$.

The different perturbations of the NMR spectrum induced by $Cr(CN)_6^{3-}$ and $Cr(1,10\text{-phen})_3^{3+}$ indicate that these reagents bind to plastocyanin at two different sites. The broadening of resonances results from an enhancement of nuclear relaxation brought about by dipolar coupling with the relatively slowly relaxing electron spin of the Cr(III) ion. The broadening is dependent on the inverse 6th power of the distance of the amino

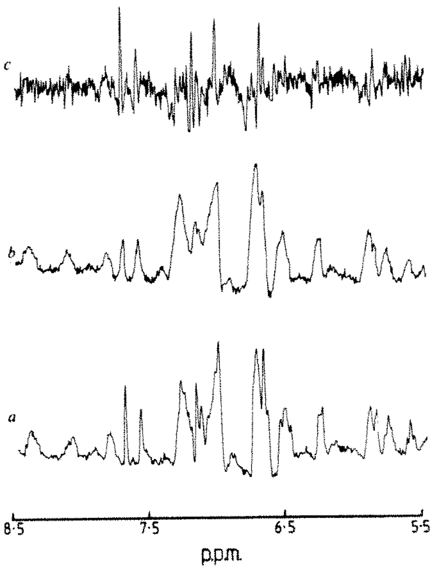

Fig. 1 Aromatic region of the resolution-enhanced NMR spectrum of French bean plastocyanin (3.5 mM, *p*H 6.3, 50 mM phosphate buffer in D_2O) in the presence of no $Cr(CN)_6^{3-}$ (*a*) and 0.4 mM $Cr(CN)_6^{3-}$ (*b*). *c*, Difference spectrum (*a* − *b*). In *a* and *b* the resolution has been enhanced by means of the convolution difference technique[16]. The residual HOD peak was suppressed by selective gated irradiation. Dioxan was used as an internal standard but all peaks are referred to TSS (trimethylsilylpropanesulphonic acid). The *p*H values quoted are uncorrected meter readings. Plastocyanins were prepared by a modification of the method of Ramshaw *et al.*[17].

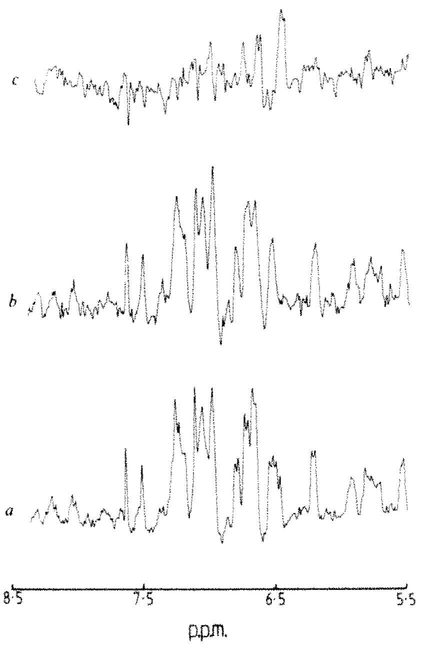

Fig. 2 Aromatic region of the resolution-enhanced NMR spectrum of cucumber plastocyanin (3.5 mM, *p*H 7.0, 50 mM phosphate buffer in D_2O) in the presence of no Cr(1,10-phen)$_3^{3+}$ (*a*) and 0.4 mM Cr(1,10-phen)$_3^{3+}$ (*b*). *c*, Difference of direct spectra obtained before and after addition of 0.4 mM Cr(1,10-phen)$_3^{3+}$.

acid residue(s) from the paramagnetic centre. Consequently, any resonances broadened by the addition of the Cr(III) complexes must arise from amino acid residues close to the sites of binding to the protein. One site, to which Cr(CN)$_6^{3-}$ binds, must lie close to the copper atom itself, as the resonances of three of the copper ligands are broadened. The resonances of His 87 are observed to broaden first. The copper atom lies at one end of the protein molecule in a depression lined by conserved hydrophobic residues and is protected from solvent by the imidazole group of this histidine residue[10]. It is conceivable that positive charge from the copper atom is delocalised over this imidazole ring which would be sufficient to bring about an electrostatic interaction with Cr(CN)$_6^{3-}$.

The second site must lie in the vicinity of Tyr 83 because the resonances of this residue are broadened by the binding of Cr(1,10-phen)$_3^{3+}$. The side chain of Tyr 83 lies close to the surface of the protein about 10 Å from the copper atom and is adjacent to a cluster of carboxylate groups[10] belonging to conserved acidic residues. This 'pocket' of negative charge is unique in plastocyanin and clearly provides a favourable binding site for positively charged reagents. Our NMR studies show that Cr(NH$_3$)$_6^{3+}$ also binds at this site (D.J.C., M.T.H. and P.E.W., unpublished observations).

Our results suggest that the charge on the inorganic reagent has a dominant role in determining the site of interaction on the protein. Sykes and coworkers[9] have shown that oxidation reactions involving Co(1,10-phen)$_3^{3+}$ are blocked by Cr(1,10-phen)$_3^{3+}$, indicating conclusively that these reagents compete for a single binding site on the protein from which electron transfer occurs. Furthermore, we expect Cr(CN)$_6^{3-}$ to bind at the same site as Fe(CN)$_6^{3-}$ in view of their similar size and identical charge and ligands. The existence of two binding sites for redox reagents on plastocyanin is not unexpected in view of the electron transport function of the protein[15].

The rate constants for the reactions of parsley plastocyanin with Fe(CN)$_6^{3-}$ and Co(1,10-phen)$_3^{3+}$ are both *p*H dependent but have different pK_a values (5.7 and 6.1, respectively)[7,9]. In addition, the reciprocal of the first order rate constant, k_{obs}, is inversely proportional to the oxidant concentration[7]. These observations led Sykes and coworkers to conclude that productive complexes are formed before electron transfer and that at least two binding sites are involved which they supposed to be in the same locality of the protein[9]. In our present NMR studies we have identified these two binding sites on plastocyanin. One is close to the copper atom and the other is at least 10–15 Å away. This observation confirms earlier suggestions based on the X-ray crystal structure[10] that two electron transfer pathways to and from the copper atom are used in the redox reactions of plastocyanin and that possibly two mechanisms of electron transfer are involved.

We thank the Australian Research Grants Committee for financial support (grant C74/15398 to H. C. Freeman) and the use of facilities at the National NMR Centre, and Professor H. C. Freeman for helpful discussions and for providing the structural information, based on the results of the crystallographic refinement at 1.6 Å resolution (Guss, J. M. and Freeman, H. C., unpublished), which has been cited in this paper. D.J.C. acknowledges the award of a Henri Berti and Florence Mabel Gritton Research Fellowship by the University of Sydney.

The β-globin gene is on the short arm of human chromosome 11

Linda Sanders-Haigh, W. French Anderson & Uta Francke*

Laboratory of Molecular Hematology, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, Maryland 20205
*Department of Human Genetics, Yale University School of Medicine, New Haven, Connecticut

Investigations on the regulation of human globin gene expression are assisted by a knowledge of the chromosomal location of the globin genes. Previous studies[1] have mapped the α-globin locus to human chromosome (HC) 16, and have shown that the human globin gene complex γ-δ-β co-segregates with lactate dehydrogenase A (LDH-A) and the presence of HC 11 in somatic cell hybrids[2,3]. Radioactively labelled globin complementary DNA (cDNA) probes were used in molecular hybridisation experiments to determine the chromosomal locations of the α- and β-globin genes. When human × rodent somatic cell hybrids are used which contain well-defined parts of human chromosomes, direct mapping of genes of chromosomal regions or single bands is possible[4,5]. We have regionally localised the human β-globin gene using two sets of hybrid cell lines: (1) Chinese hamster × human hybrid cells containing the HC 11 long arm or both the short and long arms and (2) mouse × human hybrids containing only the HC 11 short arm. The techniques of liquid molecular hybridisation[3] and Southern blotting[6] with ^{32}P-labelled human β–globin cDNA (from plasmid JW102)[7] have been used to localise the β-globin gene sequence to region 11p11 → 11p15. Similar results were reported recently by Jeffreys *et al.*[8].

0028-0836/80/070683—04$01.00

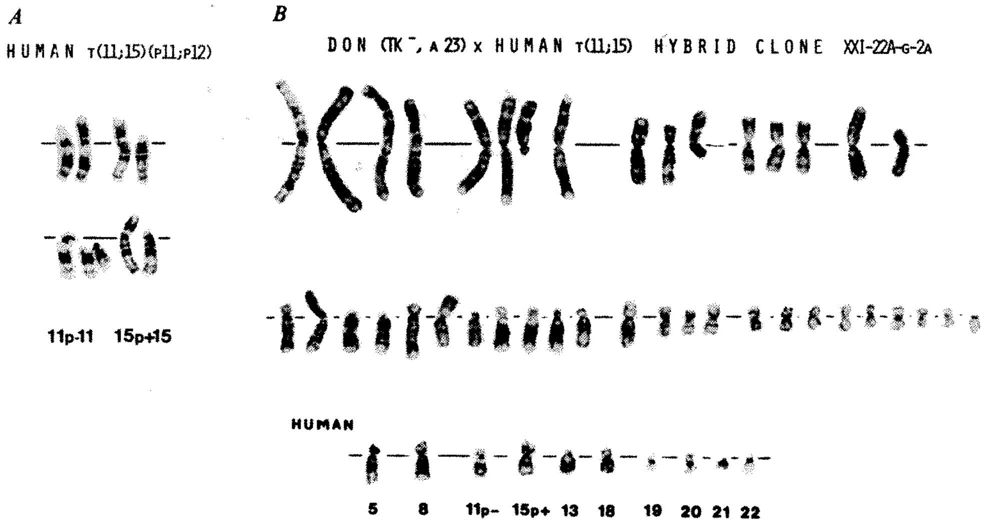

Fig. 1 *A*, Chromosome pairs 11 and 15 showing balanced reciprocal translocation t(11; 15) (p11; 12). The rearranged chromosomes der(11), or 11p-, and der(15), or 15p+, are placed to the left and the normal homologues 11 and 15 to the right of each pair. Trypsin–Giemsa banding was carried out according to Francke and Oliver[12]. *B*, Karyotype of Chinese hamster (Don, TK⁻) × human t(11; 15) hybrid clone with trypsin–Giemsa banding. The human chromosomes are arranged in the bottom line. Both translocation chromosomes are present but the normal chromosome 11 has been lost.

Chinese hamster × human cell hybrids containing the long arm of HC 11 were obtained when skin fibroblasts from a balanced carrier of a 46, XY, t(11; 15) (p11; p12) translocation (Fig. 1*A*) were fused to Chinese hamster Don cells (a23; TK⁻) using polyethylene glycol as a fusogen[9]. Cell hybrids were selected in hypoxanthine/aminopterine/thymidine (HAT) medium. The translocation chromosomes der(11) or 11p- (region 11p11 → qter) and der(15) or 15p+ (region 11pter → p11) and the normal HC 11 segregated randomly. After screening many primary hybrid clones for their content of chromosomes containing HC 11 material, and after two rounds of subcloning, we have isolated a number of independent primary and secondary hybrid cell lines which have retained the der(11) chromosome at high frequency and have lost the normal HC 11 and the der(15) translocation product. These clones do not express human LDH-A, while others containing both translocation chromosomes after loss of the normal HC 11 (Fig. 1*B*), are positive for LDH-A expression. These results are consistent with the previous localisation of LDH-A to band 11p12 (ref. 10).

Mouse × human somatic cell hybrids containing the short arm of HC 11 were obtained when BALB 3T3 cells deficient in thymidine kinase (TK) were fused to human fibroblasts with a t(11; 17) (p15; q21) balanced translocation. In subclones a secondary rearrangement was identified and characterised as 11cen → 11p15 :: 17q21 → 17qtr (mar-1). This telocentric marker chromosome carries the human gene for TK (in region 17q21 → 17qtr) and the gene for LDH-A (in region 11cen → 11p15)[4]. This chromosome is selectively retained in cell hybrids grown in HAT medium because it carries the human TK gene, complementing the enzyme defect in the murine parental cell line. In fact, mar-1 was the only human chromosome retained in hybrid clones VII-2,3 and 4 HAT, as demonstrated by Hoechst 33258 and Giemsa 11 staining. (A cell line derived from one of these hybrid clones has been designated LBP-2 in the laboratory of Dr Walter Bodmer and has been used by Jeffreys *et al.* in similar experiments to those described here[8].) After counter selection in 5-bromodeoxyuridine (BUdR)-containing medium, derivative clones lacking mar-1 have been obtained (VII-2 and 4, BUdR)[11]. These back-selected clones no longer express LDH-A.

Hybrid clones from both sets of experiments were characterised cytologically by trypsin–Giemsa banding and karyotyping (Fig. 1*A*, *B*), and biochemically by LDH electrophoresis

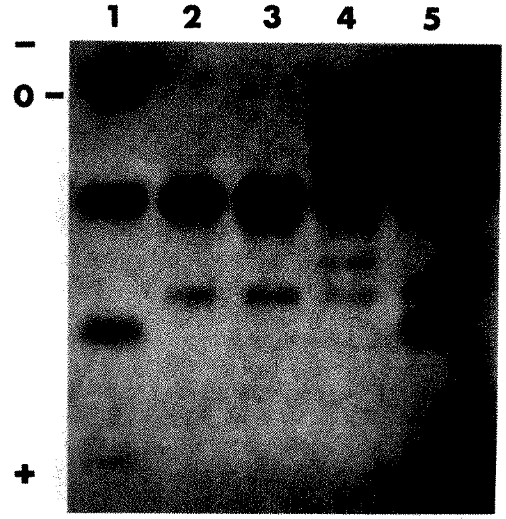

Fig. 2 Lactate dehydrogenase electrophoresis on Cellogel[13]. Cell extracts: 1, Human fibroblast; 2, mouse 3T3/TK- parental cells; 3, hybrid clone VII-2 BUdR; 4, hybrid clone VII-2 HAT; 5, mixture of extracts (1) and (2). The hybrid in channel 3 is negative and the one in channel 4 is positive for human LDH-A.

*Between 15 and 30 metaphase cells per clone were analysed. Results are presented as average frequency of respective chromosome per cell.

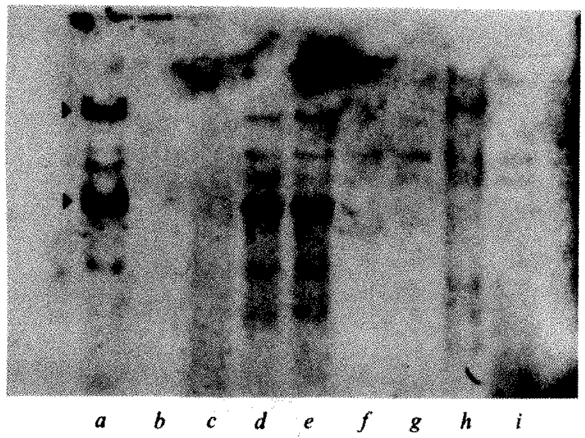

Fig. 3 Southern DNA blotting of hybrid clones and controls. Hybrid cells were collected for karyotyping, LDH-A analysis, and DNA extraction all from the same (or from a very close) passage. The cells were pelleted, and resuspended in 50 mM EDTA, 0.5% SDS, and 100 μg ml^{-1} proteinase K (Beckman). DNA extraction proceeded by addition of an equal volume of 1:1 chloroform:phenol, separation of the phases, addition of an equal volume of chloroform:isoamyl alcohol (24:1) to the aqueous phase, separation of the phases, and two ethanol precipitations. The nucleic acid was pelleted at 10,000 r.p.m. for 45 min, and resuspended in SSC (0.15M NaCl + 0.015 M Na citrate, *p*H 7.0). RNase (previously boiled for 10 min to inactivate residual DNase) was added to a concentration of 100 μg ml^{-1} and incubated at 37 °C for 1 h. Extraction with phenol:chloroform was performed, followed by a second ethanol precipitation. The DNA pellet was resuspended in deionised water and dialysed for 2 d in Tris-EDTA (100 mM Tris-HCl, *p*H 7.2, 0.5 mM EDTA). 100-μg samples of each hybrid DNA were digested for 2 h at 37 °C with *Eco*RI (Boehringer Mannheim) 2 units per μg, and electrophoresed in 1% agarose. The DNA was blotted on to nitrocellulose filters in 6 × SSC. The blots were prehybridised in 0.02% Ficoll, 0.02% polyvinylpyrollidone, 50 μg ml^{-1} denatured salmon sperm DNA, 10 μg ml^{-1} poly(A) and 0.1% SDS to prevent nonspecific hybridisation of the β-globin probe. The cDNA probe was prepared from plasmid JW102[7] which was digested with *Hha*I and separated by size on an alkaline sucrose gradient (5–20% sucrose in 10 mM Tris-HCl, *p*H 7.5, 100 mM NaCl, 1 mM EDTA). The largest fragment, which contains the β-globin insert was collected by ethanol precipitation. This fragment was then incubated in the presence of ^{32}P-dCTP, DNase and *E. coli Pol*I for nick translation[3,14]. The DNA was extracted with phenol, collected in the void volume peak on a Sephadex G-50 column, and precipitated with ethanol. The resulting double-stranded probe had a specific activity of approximately 2–4 × 10^8 c.p.m. μg and was used for the Southern blotting procedure[6]. The lyophilised cDNA probe was resuspended in the prehybridisation solution described above, boiled to denature it, and added to the nitrocellulose filters in a Scotchpak bag. Hybridisation was carried out at 65 °C for 72 h. After hybridisation, the blots were washed in several changes of prewarmed SSC, and autoradiographed with intensifying screens at −80 °C for 48 h. Upper and lower arrows indicate *Eco*RI human β-globin fragments of 6.2 and 4.0 kilobases, respectively. These correspond to the 5.2 and 3.2 kilobase fragments reported by Lawn *et al.*[15]. The large amount of DNA loaded on the gel causes these fragments to migrate more slowly. *a*, Human spleen DNA; *b*, XXI 61A; *c*, XXI 23A-2d; *d*, VII-2 HAT; *e*, VII-3 HAT; *f*, VII-2 BrdU; g, VII-4 BrdU; *h*, Don cell DNA; and *i*, mouse liver DNA.

(Fig. 2). DNA was extracted from each cell for liquid molecular hybridisation or Southern blotting to detect human β-globin gene sequences.

All hybrid cell clones were expanded to 5 × 10^8 cells, and an aliquot of each was examined for LDH-A. The LDH-A analysis was used as a marker to monitor the presence of the short arm of HC 11. The remainder of the cell pellet was extracted for DNA as described in the legend to Fig. 3.

For Southern blotting, a 100-μg sample of each hybrid DNA was digested with *Eco*RI, electrophoresed in 1% agarose, blotted on to nitrocellulose filters and annealed in stringent conditions to ^{32}P-labelled pure human β-globin cDNA (obtained from the recombinant cDNA plasmid JW102). Thirteen hybrid clones were analysed (Fig. 3; Table 1). Two bands which hybridised strongly to human β-globin cDNA were present in the human spleen control DNA (Fig. 3, lane *a*). Several lighter bands were present in all DNA samples including the Chinese hamster (Fig. 3, lane *h*) and mouse liver (Fig. 3, lane *i*) control DNA, and probably represent cross-reactivity of the human β-globin cDNA with other sequences. The five clones positive for LDH-A were also positive for the human β-globin gene (Fig. 3, lanes *d*, *e*; Table 1); the eight clones negative for LDH-A were also negative for the human β-globin gene (Fig. 3, lanes *b*, *c*, *f*, *g*; Table 1).

Liquid molecular hybridisation was carried out, as described previously[3], on six hybrid clones (Table 1, Fig. 4). Two were positive for LDH-A and the human β-globin gene; four were negative for both.

Thus, in both the Southern blot and the liquid molecular hybridisation assays, those hybrids containing the short arm of HC 11 and expressing human LDH-A were positive for the presence of the human β-globin gene, while those clones containing only the long arm of HC 11 were negative for the β-globin gene. Since p15 is the breakage point of mar-1, and 11p11 the breakpoint in the t(11; 15) translocation, the β-globin gene complex can be limited to region 11p11 → 11p15 of the human chromosome.

These mapping studies may be of significance in the study of regulatory phenomena involving the γ-δ-β globin loci. Since in mar-1 the short arm of HC 11 (containing the β-globin gene region) is attached to HC 17 (containing thymidine kinase) this

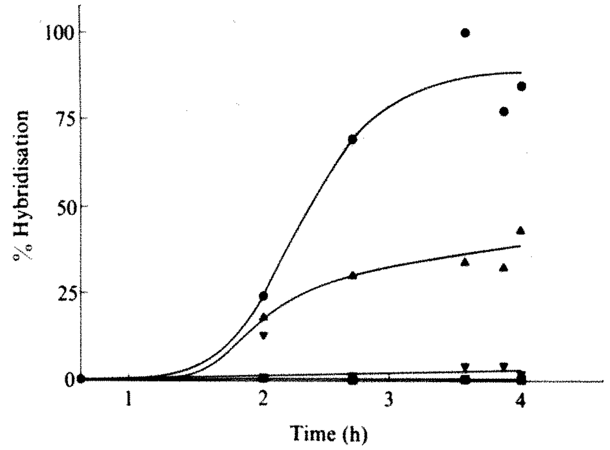

Fig. 4 Liquid molecular hybridisation of hybrid cell DNA to ^{32}P-labelled human β-globin cDNA. Hybrid cells were pelleted and extracted for DNA as described previously[3]. The double-stranded ^{32}P-labelled β-globin cDNA probe, prepared as described in the legend to Fig. 3, was further purified by hybridisation to adult human reticulocyte mRNA in 50% formamide and 3 × SSC at 66.5 °C. This temperature prohibits DNA duplex formation but allows DNA·mRNA hybridisation, which then protects the antimessage strand from subsequent digestion with S$_1$ nuclease. After addition of *E. coli* carrier DNA and alkaline buffer, the duplex was separated on a 5–30% alkaline sucrose gradient. The hot peak of 500–800 nucleotide material was pooled, neutralised, and precipitated in ethanol. The precipitate was dissolved in deionised water and desalted over a Sephadex G-25 column. The purity of the ^{32}P-labelled, single-stranded β-globin specific cDNA was tested by annealing to probe at increasing concentrations of adult human reticulocyte mRNA. For detection of the human β-globin gene in hybrid DNA, the sonicated DNA of each cell line was lyophilised in 3-mg aliquots and mixed with a cocktail of 50% formamide, 3 × SSC, and ^{32}P-labelled probe. The reaction was divided into 20-μl aliquots and sealed in glass capillary tubes coated with *E. coli* DNA to minimise sticking. All reactions were boiled for 15 min to denature the DNA and allowed to reanneal at 52.5 °C. Time points were taken from 10 min to 100 h to generate the C_0t curve. All time point samples were divided, and one-half of each digested with S_1 nuclease to determine the per cent hybridisation of each sample. (●) Human spleen DNA; (▲) XXI 22A-g; (▼) XXI 22A-g-2b; (■) Don cell DNA.

translocation product may be selectively retained in cell hybrids maintained in HAT medium. Fusion of VII-2 HAT with TK⁻ 2S mouse erythroleukaemia cells[3] should result in cell hybrids in which the human β-globin gene is maintained in an established mouse erythroid tissue culture cell line. Studies are now underway to obtain this proposed hybrid line.

We thank Kathy Li for preparing cDNA probes, Mary Grace West and Amy Davidoff for assistance with the cell cultures, and Dr Bernard Forget for the recombinant cDNA plasmid JW102. This work was supported in part by USPHS research grants GM-21110 and GM-26105 (to U.F.); and was in partial fulfillment of the requirements for a PhD in Genetics at the George Washington University (for L. S.-H.).

Satellite DNA is transcribed on lampbrush chromosomes

Jennifer M. Varley, Herbert C. Macgregor & Harry P. Erba

Department of Zoology, University of Leicester,
Leicester LE1 7RH, UK

During the lampbrush stage of oogenesis there is widespread transcription, and it has been estimated that the total amount of DNA transcribed may be an order of magnitude greater than that required to produce the necessary functional RNA for the oocyte[1]. We therefore considered it likely that some of the transcribed sequences have little, if any, translational significance, and may include both middle repetitive[2] and highly repeated, or satellite, sequences. Satellite DNA is generally defined as rapidly reannealing DNA which has a short basic sequence that is repeated millions of times in the genome, usually in tandem arrays[3,4]. The short repeated length, coupled with the organisation of satellite sequences in high order molecular weight tandem arrays in heterochromatic regions, have been put forward as reasons for supposing that this type of DNA is not normally transcribed[5]. We report here that we have looked for and found evidence of transcription of satellite DNA on lampbrush loops in oocytes of the crested newt, *Triturus cristatus carnifex*.

The technique that we have used to detect transcription is that of DNA/RNA-transcript hybridisation[6], where a radioactively labelled DNA probe is hybridised to nascent RNA transcripts on the lampbrush loop. Preliminary studies using this approach[7] indicated that highly repeated DNA sequences are transcribed around some lampbrush loops during oogenesis in *T.c. carnifex*. However, the probe used in these experiments undoubtedly

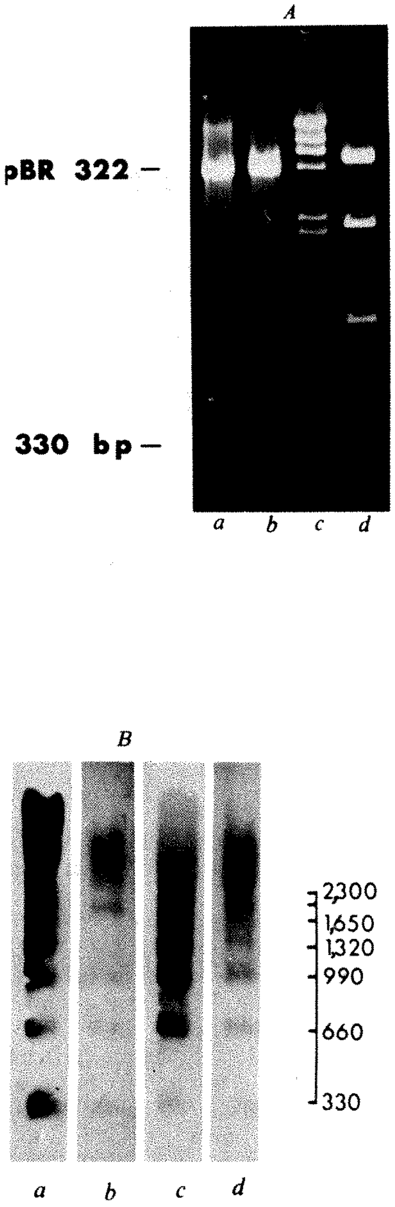

Fig. 1 *A*, Analysis of recombinant plasmids pTcS1 and pTcS2 by restriction endonuclease cleavage and electrophoresis on a 1% agarose gel. pTcS1 and pTcS2 were digested with *Bam*HI (tracks *a*, *b*). Linear pBR322 and a 330-base pair fragment are resolved as indicated. Tracks *c* and *d* show *Hin*dIII digests of λ and PM2, respectively. pTcS1 and pTcS2 had been produced by ligating pBR322 cleaved with *Bam*HI and the partially purified *Bam*HI 330-base pair satellite sequence. Clones containing plasmids that failed to confer tetracycline resistance were grown in M9 medium containing 100 μg ml^{-1} ampicillin at 37 °C. The plasmids were amplified using chloramphenicol (250 μg ml^{-1})[18] and covalently closed circular plasmid DNA was isolated as supercoils by lysozyme-Brij 58-Na deoxycholate lysis of the cells[19] followed by centrifugation in caesium chloride–ethidium bromide. Plasmids containing *T.c. carnifex* DNA were propagated under P2 containment as defined by the NIH. *B*, Autoradiographs of nitrocellulose filters which have been hybridised to pTcS1 and pTcS2 nick translated with [α-^{32}P]dCTP (Radiochemical Centre; Code no. PB 205; specific activity 2–3,000 Ci mmol^{-1}). Tracks *a* and *c* represent transfers of total *T.c. carnifex* DNA digested with *Bam*HI, tracks *b* and *d* represent total *T.c. carnifex* DNA digested with *Kpn*I, which also cleaves once within this 330-base pair repeat. Tracks *a* and *b* have been hybridised with pTcS1, tracks *c* and *d* with pTcS2. In each case, a ladder of sequences representing multimers of the 330-base pair repeat hybridise to the cloned fragments, showing that the cloned fragment represents a tandemly repeated satellite sequence. Autoradiography was carried out for 2–5 days at −20 °C using an Ilford fast tungstate intensifying screen.

0028-0836/80/070686—03$01.00

contained some middle repetitive and unique DNA sequences, which could have been responsible for the results obtained. To determine whether satellite DNA is transcribed during oogenesis, we have isolated a 330-base pair satellite sequence from total *T.c. carnifex* DNA by digestion with the restriction endonuclease *Bam*HI. This restriction fragment was inserted into the *Bam*HI site in the tetracycline resistance gene in pBR322 (ref. 8). Plasmid DNA was purified from cultures of *Escherichia coli* K12 strain HB101 (ref. 9) containing the recombinant plasmid, and digested with *Bam*HI. After agarose gel electrophoresis, bands corresponding to linear pBR322 and to a sequence 330 base pairs long (Fig. 1*A*) were visible. To confirm that the 330-base pair sequence was a monomer of a tandemly repeated satellite, two of the recombinant clones, pTcS1 and pTcS2, were labelled *in vitro* with $[\alpha^{32}P]$dCTP. These probes were then hybridised to total *T.c. carnifex* DNA that had been digested with *Bam*HI, electrophoresed on agarose and transferred to nitrocellulose filters[10]. Both clones hybridised to a ladder of sequences corresponding to monomers and multimers of a 330-base pair sequence (Fig. 1*B*), confirming that we had cloned a tandemly repeated sequence.

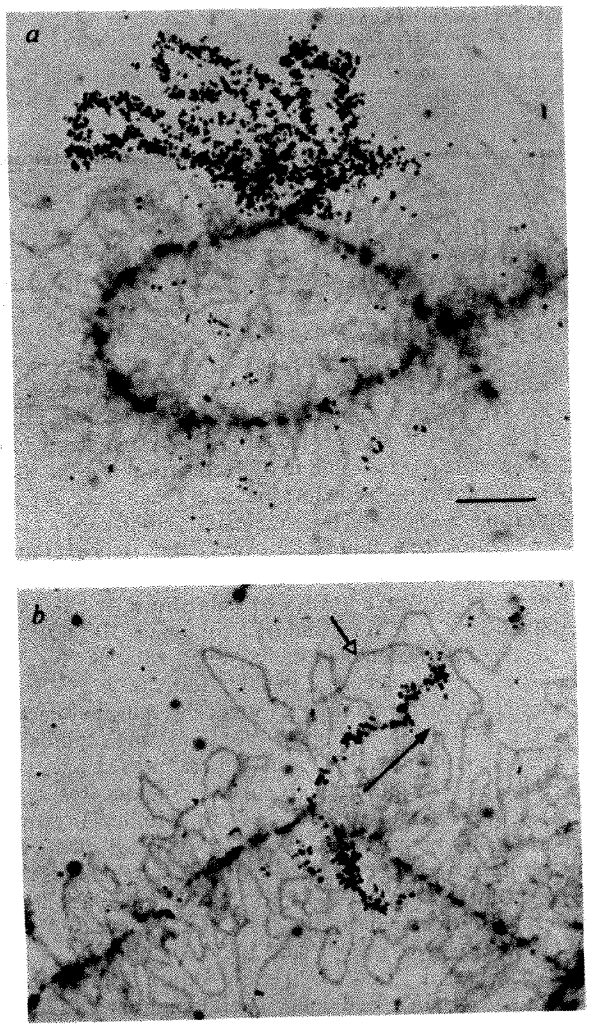

Fig. 2 Light micrographs of DNA/RNA-transcript hybrids of ^{3}H-labelled pTcS1 DNA onto lampbrush loops of *T.c. carnifex*. Lampbrush chromosomes were isolated as described previously[12], but were fixed in 70% ethanol only. Hybridisation was carried out in 50% formamide, 4 × SSC at 37 °C for 12 h (ref. 2). The specific activity of the probe was 2×10^6 c.p.m. per μg and 1–2×10^5 c.p.m. were used per preparation. The autoradiographic exposure time was 2–4 days. Scale bar, 10 μm. *a*, Heavily labelled multiple loops at 8 units (ref. 16) on the heteromorphic long arm (HTA) of chromosome I. The level of labelling is very high over the whole length of the loop. *b*, Partially labelled loop pair at 54 units (ref. 16) on the HTA of chromosome I. There is a distinct gradient in the amount of silver grains, indicating that transcription proceeds in the direction shown (arrow). The unlabelled region can also be seen (open arrow).

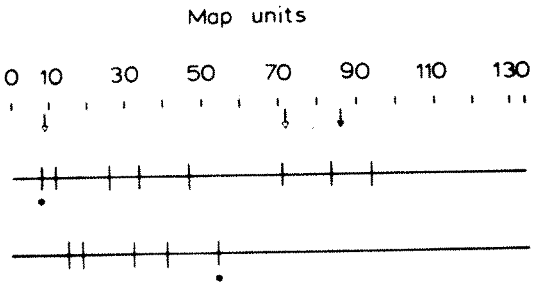

Fig. 3 Diagrammatic representation of the loops labelling on chromosome I of *T.c. carnifex* using pTcS1 to hybridise to the nascent RNA transcripts. The numbers associated with each loop give the distance from the left end of the chromosome in terms of units described by Callan and Lloyd[16]. The labelled loop pairs are drawn as bars on a line that represents the entire length of chromosome I. The centromere is at 86 units (arrow), and the heteromorphic region (HTA) lies between 9 and 72 units (open arrows). The top line represents the longer HTA, the bottom line the shorter HTA. The two loop pairs marked with asterisks are those at 8 units on the long HTA and at 54 units on the shorter HTA that are shown in Fig. 2. Conditions of hybridisation were as described in Fig. 2 legend.

DNA from clone pTcS1 was then nick translated with ^{3}H-labelled triphosphates[11] and used as a probe in DNA/RNA transcript hybrids onto lampbrush loops from *T.c. carnifex*[12]. After a 72-h autoradiographic exposure, several loops were heavily and specifically labelled. Most of these loops were situated on the long arm of chromosome I (Figs 2, 3). Results using the cloned satellite sequence confirm and extend results obtained using highly repeated DNA isolated by renaturation kinetics, by caesium salt centrifugation and by isolation of restriction fragments from agarose gels[13]. The level of labelling over some of the loops, and the short autoradiographic exposure needed, indicate that in some cases, the loop RNA consists almost exclusively of satellite DNA transcripts (Fig. 2*a*).

Ribonuclease treatment of lampbrush chromosome preparations (2 h at 37 °C in a solution of 100 μg ml^{-1} ribonuclease A and 1,000 units ml^{-1} ribonuclease T1 in 1 × SSC) before incubation with labelled pTcS1 completely eliminated *in situ* hybridisation. No part of any lampbrush chromosome or any other structure became labelled in our autoradiographs, even after exposures of several weeks. Pretreatment of preparations with deoxyribonuclease 1 left the level of *in situ* hybridisation with pTcS1 unimpaired. Labelled, alkali-denatured pBR322 DNA was also used as a control, using precisely the *in situ* hybridisation and washing conditions as for pTcS1. Autoradiographs of pBR322 preparations were completely negative.

There are two important aspects to this study. The first is that we consider that our data provide the first clear evidence that DNA belonging to the satellite class is transcribed during the lampbrush stage of oogenesis in *T.c. carnifex*. The second is related to the unusual structure of the long arm of chromosome I in this species, and will be discussed later.

We consider it unlikely that the RNA transcribed from a satellite sequence will be translated. If it were, then any polypeptide produced would be very unusual. However, the question that remains is why satellites should be transcribed at all during the lampbrush stage of oogenesis. One possibility is that the RNA transcripts of satellite sequences in some way regulate the expression of other, possibly translatable, sequences in the germinal vesicle. Such control would be stage specific, and studies on this problem are in progress in our laboratory. A second explanation might be that transcription of satellite sequences in the germinal vesicle is incidental, and that on a lampbrush loop the RNA polymerases overrun normal termination signals and read right through stretches of satellite DNA. The majority of the highly repeated DNA in *T.c. carnifex* is clustered in pericentric regions, and on the long arm of chromosome I (refs 7, 13, 14). If transcription does overrun normal termination signals, satellite DNA is more likely to be transcribed on chromosome I simply because there is so much of it in this region.

The presence of highly repeated DNA on the long arm of chromosome I correlates in an unknown way with structural heteromorphism and a lack of chiasma formation in this chromosome arm in *Triturus cristatus*[14–17]. We have evidence that the distribution of the satellite sequences on the two long arms of chromosome I may be different[13]. We do not know why such a situation should exist, what evolutionary significance it may have, or why satellite DNA should be transcribed on this unusual chromosome.

This work was supported by SRC grant no. GR/A86466. We thank Dr Joseph Gall for providing us with the facilities for cloning the satellite DNA in the Department of Biology, Yale University. H.P.E. is a Fulbright Scholar in the University of Leicester, but his contribution to this work was largely carried out in Dr Gall's laboratory with the support of NIH grant no. GM 12427.

Oocytes in the testis

Anne McLaren

MRC Mammalian Development Unit, Wolfson House,
4 Stephenson Way, London NW1 2HE, UK

In normal sexual differentiation, XX germ cells develop into oocytes in an ovary, and XY germ cells undergo spermatogenesis in a testis. In some genetic abnormalities of sexual differentiation, and other abnormal situations such as experimental mouse chimaeras, XX germ cells may be present in a male embryo[1,2]. They will still migrate into the genital ridges, but in the environment of a testis they usually degenerate at or before the onset of meiosis. Whether they pursue a male or a female pathway of development before degeneration is not yet established. Very occasionally growing oocytes have been observed within seminiferous tubules, for example in a 16-yr-old hermaphrodite who was brought up as a girl and only came to medical attention because he wished to be recognised as a boy[3]. Such tubules usually form part of an ovotestis (refs 3–5 and P. S. Burgoyne, personal communication), though large numbers of primary and growing oocytes have also been observed in apparently normal testes of two mouse chimaeras, one an 8-d-old bilateral hermaphrodite (M. Spiegelman, personal communication) and the other a 5-d-old male[6]. The phenomenon is usually confined to very young animals, apart from one adult mouse chimaera (P. S. Burgoyne, personal communication) in which the tubules were disorganised and the oocytes that they contained were hyalinised, as though they had undergone atresia. In most cases (refs 3, 5, 6 and P. S. Burgoyne and M. Spiegelman, personal communications) the individuals were known to possess both an XX and an XY cell population, and the chromosomal sex of the oocytes was not established. In contrast, I report here that a substantial proportion of genetically sex-reversed male mice, in which all cells are initially XX in chromosome constitution, contained healthy growing oocytes within their testes up to at least 15 days of age.

The autosomal gene *Sex-reversed* (*Sxr*)[7] causes genetically female (XX) mice to develop as phenotypic males. Such *Sxr*/+ XX males are sterile, as the XX germ cells are unable to undergo spermatogenesis. Apart from the absence of germ cells, the testes are grossly normal in morphology. Cattanach *et al.*[7] examined some testes of sex-reversed mice in the prenatal and early postnatal period, and concluded that the XX germ cells, although present initially, are lost by 10 days of age.

During a further study of the testes of prepubertal *Sxr*/+ XX mice, I examined serial sections of 21 testes from sex-reversed mice, heterozygous for X-linked coat-colour markers and killed between 8 and 18 days of age. Six proved to contain growing oocytes. No oocytes were found in 30 testes from normal male sibs in the same age range. The fact that Cattanach *et al.*[7] did not detect any growing oocytes in their material is not in conflict with the present finding, for within this age range they only examined two animals (at 10 days of age).

Three of the sex-reversed testes contained one oocyte each, one contained two, one nine, and one contained 100 oocytes. The oocytes were located within the testis tubules (Fig. 1), usually in the neighbourhood of the rete testis (Fig. 1*c*). Each was surrounded by an incomplete layer of cells, morphologically similar to the Sertoli cells lining the tubules, though somewhat more flattened, and resembling in general appearance the incomplete layer of granulosa cells surrounding oocytes in the mouse ovary at birth. No sign was seen of the follicular growth that begins in the mouse ovary about 3 days after birth. The oocytes themselves, on the other hand, had enlarged considerably since birth, measuring 30–50 μm in diameter, about the same size as ovarian oocytes of the same age. Thus at this stage of development, oocyte growth and follicular growth are not necessarily associated. The state of preservation of the oocytes varied from good, with a well defined cell membrane, an intact nuclear membrane, and a distinct nucleolus, to very degenerate. In one case the nuclear material was represented by a large number (more than 100) of very small chromosome-like bodies (Fig. 1*d*), reminiscent of the highly condensed chromosomes seen in cells blocked in metaphase (see, for example, Paterson's illustration of air-dried preparations of dying embryos homozygous for the gene *oligosyndactyly*[8]).

Twelve adult (6–9 weeks) *Sxr*/+ XX testes were also serially sectioned, but none contained oocytes (0/12 compared with 6/21; $P < 0.05$, by Fisher's exact test). This suggests that all the oocytes would have degenerated before sexual maturity was reached. Perhaps such oocytes are unable to survive the changes in the testicular environment that must occur between 1 and 2 weeks after birth in the normal male mouse, to induce the entry of XY germ cells into meiosis.

0028-0836/80/070688—02$01.00

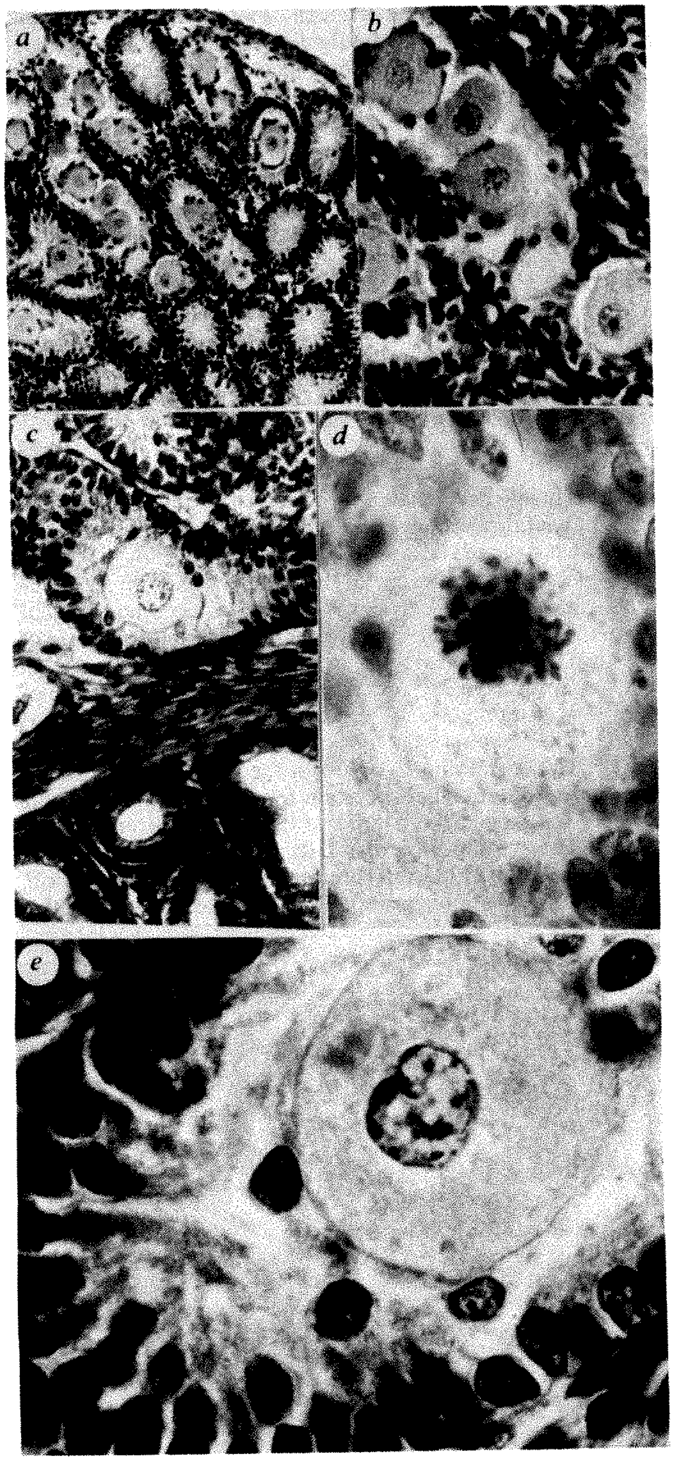

Fig. 1 *a*, Testis of 11-d-old XX *Sxr*/+ male, showing numerous growing oocytes within the intact seminiferous tubules. *b*, Higher power view of some of the tubules shown in (*a*). The oocytes are surrounded by an incomplete layer of flattened follicle-like cells. *c*, Single oocyte in tubule of 10-d-old XX *Sxr*/+ male, adjacent to rete testis. *d*, Degenerate oocyte, from 11-d-old XX *Sxr*/+ testis. Nucleus appears to have broken down into numerous small chromosome-like bodies. *e*, Growing oocyte, with intact cell membrane and nucleus, from 15-d-old XX *Sxr*/+ testis.

Does the fact that the XX germ cells in the sex-reversed testes were undergoing oogenesis, as befits their chromosomal sex, imply that they were developing autonomously? The testes of XX/XY mouse chimaeras contain initially both XX and XY germ cells. A study of such testes during the prenatal period[9] suggested that XX but not XY germ cells entered meiotic prophase before birth, at the normal time for XX germ cells undergoing oogenesis in the ovary. XY germ cells can occasionally be induced to enter meiosis prematurely[10], but apparently only if their environment is altered, for example, by transplantation beneath the kidney capsule[11], or explantation *in vitro*[12]. In the rare case of an XX↔XY chimaera gonad differentiating as an ovary, XY germ cells have been reported to undergo oogenesis; one gave rise to a functional egg[13,14]. XO germ cells, which resemble XY germ cells in having only one X chromosome, are capable of undergoing spermatogenesis if they are located in a testis, for example in an *Sxr*/+ mouse, but the spermatozoa that they form are abnormal and show little or no motility[7,15]. The few spermatogonia reported by Cattanach *et al.*[7] in the 2-d, 5-d and 6-d-old *Sxr*/+ XX testes that they examined, might therefore have been XO in chromosome constitution, as were the spermatogenic cells isolated from the occasional tubule seen to be supporting active spermatogenesis in adult *Sxr*/+XX males[15]. Alternatively, if the spermatogonia in the newborn testes were XX, it would suggest that some XX germ cells can take a male developmental pathway, others a female pathway.

If this were so, development cannot be autonomous, but must be under some environmental influence. H–Y antigen, thought to have a male-determining role in the differentiation of the testis[16,17], seems more likely to act on the somatic tissues, inducing the formation of the testis tubules, than on the germ cells. The location of the oocytes in *Sxr*/+ XX testes near the rete testis lends some support to the postulate of Byskov, that entry of germ cells into meiosis before birth is under the control of a diffusible meiosis-inducing substance (MIS)[12] produced by the mesonephric rete region in both female and male fetuses[18]. According to this postulate, germ cells in the testis would normally be protected from the effects of MIS by their location within the tubules, where a hypothetical meiosis-preventing substance, secreted perhaps by the Sertoli cells, would be present in high concentration[19]. The observations on *Sxr*/+XX germ cells reported here, as well as previous observations on XX↔XY chimaeras, would imply that germ cells with two X chromosomes are more susceptible to the meiosis-inducing influence of MIS than are germ cells with only one X chromosome, and hence are more likely to undergo oogenesis. Perhaps the germ cells that Cattanach *et al.*[7] described as spermatogonia in the newborn *Sxr*/+XX mice were those located further from the rete, that failed to come under the influence of MIS and hence started development along the male pathway.

I thank Dr B. M. Cattanach for *Sxr*/+mice.

Sequence-dependent variations in the backbone geometry of a synthetic DNA fibre

Heisaburo Shindo & Steven B. Zimmerman

National Institute of Arthritis, Metabolism and Digestive Diseases,
National Institutes of Health, Bethesda, Maryland 20205

There are many examples of proteins which interact with specific DNA sequences (see references cited in refs 1 and 2). It is not clear whether specificity is derived from proteins sensing directly the base sequence of the DNA or is a result of unique secondary or tertiary structural features induced by certain DNA sequences. Recent studies have indicated the occurrence of several types of symmetries and sequence irregularities in DNA regions which interact with regulatory proteins, but they do not provide information on three-dimensional structure[3]. The Watson–Crick base-paired double helix can be observed in different conformations[4–6], depending on humidity and salt concentration. Within the limited resolution of X-ray fibre diffraction at high relative humidity and in the appropriate salt conditions, studies indicate that natural DNA as well as synthetic repeating polynucleotide duplexes adopt essentially the same average secondary structure, namely the B conformation[7]. This implies that all residues adopt a single backbone conformation. Recently, however, a high-resolution proton NMR study[8] has demonstrated that a change from a regular conformation may occur at the junction region of block copolymers. ^{31}P NMR studies strongly suggest that alternating polynucleotides can have alternating backbone conformations in solution[9,10]. Klug *et al.*[11] have proposed an alternating structure for poly(dAdT)·poly(dAdT), based on a single crystal X-ray diffraction study of the tetranucleotide, dA-dT-dA-dT (ref. 12). We report here structural ^{31}P NMR studies which show the existence of such variation in the fibre form of a synthetic DNA, poly(dAdT)·poly(dAdT). This confirms our earlier conclusion[13] that natural DNA has a non-uniform backbone conformation.

Figure 1 shows an X-ray diffraction image from a poly(dAdT)·poly(dAdT) fibre at high relative humidity; the pattern is similar to the B form patterns reported by Davies and Baldwin[14]. From this image, the pitch and the rise per residue were found to be 32.3 and 3.3 Å, respectively, corresponding to 9.8 residues per turn. This implies that the alternating copolymer is in the B conformation in these conditions.

Figure 2 compares the ^{31}P NMR spectra at 24.3 MHz from natural DNA fibres and poly(dAdT)·poly(dAdT) fibres at two different fibre orientations relative to the magnetic field, H_0. Observed NMR parameters are shown in Table 1. Strikingly, poly(dAdT)·poly(dAdT) fibres when orientated parallel to the magnetic field exhibit two well defined resonances, whereas natural DNA exhibits a single broad resonance in the same conditions (Fig. 2). The former result is consistent with the observation of a doublet in the ^{31}P spectrum for a 145 base-pair poly(dAdT)·poly(dAdT) fragment in solution[10]. As the two resonances occur in nearly equal intensity, these results strongly imply an alternating conformation of the phosphodiester groups of DNA both in solution and in the solid state, stemming from the alternating base sequence of this polymer. As discussed previously[13], the line width of the parallel spectrum is partly a result of imperfect orientation of the molecules relative to the fibre axis. We observed two resonances with a separation of 21 p.p.m. in the parallel spectrum for poly(dAdT)·poly(dAdT). The total line width is 39 p.p.m., of which instrumental factors and magnetic susceptibility may account for ≤5 p.p.m. Thus, the individual line width can be estimated to be about 13 p.p.m. (that is, 39 − 5 − 21 p.p.m.). This estimated value corresponds to that calculated for a 4–6 degree deviation of the helical axis about the long axis of the fibre[13]. In other words, the observed individual line width for poly(dAdT)·poly(dAdT) can be explained by a small amount of molecular disorientation in the fibre. Applying similar reasoning to the natural DNA spectra, the distribution of chemical shifts extends over 24 p.p.m. (that is, 42 − 5 − 13 p.p.m.), which we take as a reflection of the limit of variation in the orientation of the phosphodiester group in DNA with heterogeneous sequences. The deviation in the orientation of the phosphodiester group in natural DNA was previously estimated to be of the order of ±20° from the average orientation about any of the individual orthogonal axes[13]. Note that the extremes of this range may be related to ribose ring puckering[12], but do not necessarily imply large changes either in base stacking conformations or in individual dihedral angles of the backbone. Thus, we conclude that irregularity in the backbone conformation is an ubiquitious phenomenon not restricted to a small region of DNA; presumably the irregularity is sequence-dependent. This irregularity of phosphodiester conformation is, of course, highly accentuated in poly(dAdT)·poly(dAdT). The high affinity of the *lac* repressor for this duplex[15–18] may depend on just such structural characteristics.

The average chemical shift of the parallel spectrum for natural DNA occurs between the two resonances of poly(dAdT)·poly(dAdT). This implies that the conformations of the phosphate group in ApT and TpA sequences deviate in opposite senses from its average conformation in the B form of DNA. It is of interest that the one resonance, which is shifted downfield by 12 p.p.m. from the peak of the parallel spectrum of natural DNA (see Table I), occurs at the position of the maximum peak of the parallel spectrum for the A form of natural DNA[13]. This may suggest that the orientation of one of the phosphodiester groups is similar to its orientation in the A form of DNA. One plausible interpretation for the chemical shift changes is that the ionic group, O=P—O⁻, of the one of the

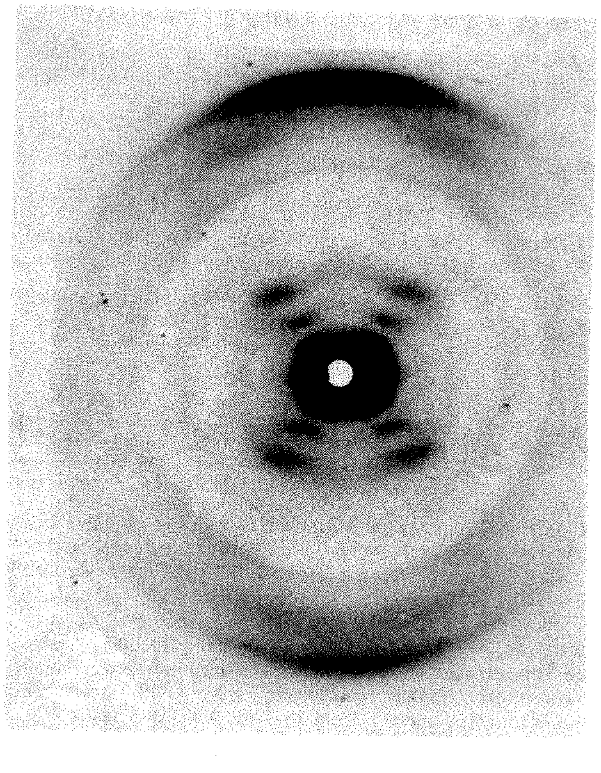

Fig. 1 X-ray diffraction photograph from a poly(dAdT)·poly(dAdT) fibre at room temperature and 98% relative humidity. The alternating copolymer (P. L. Biochemicals) was dissolved in a small amount of 10 mM NaCl, heated in a boiling water bath for about 1 min, and then cooled slowly to room temperature. The fibres were formed at 4 °C; otherwise their preparation and the collection of the diffraction pattern are as described previously[20].

0028-0836/80/070690—02$01.00

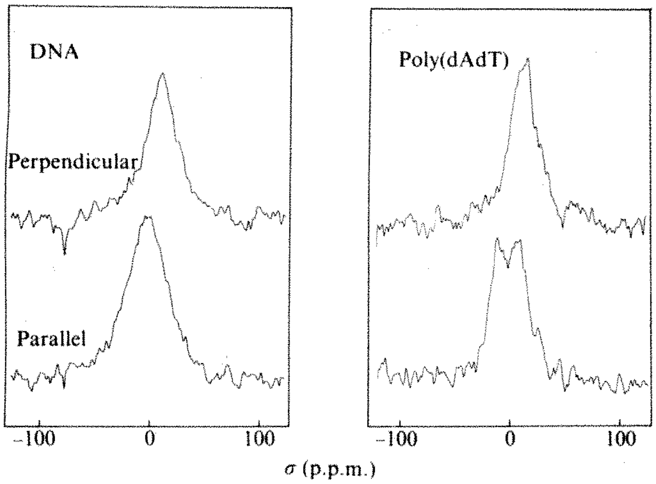

Fig. 2 The proton dipolar decoupled and cross-polarised ^{31}P NMR spectra (24.3 MHz) at 25 °C from poly(dAdT)·poly(dAdT) fibres (right) and salmon sperm DNA fibres (left). The top spectra for both DNAs were obtained from perpendicular-orientated fibres (relative to the magnetic field) and the bottom spectra from the parallel-orientated fibres. The method of controlling humidity and instrumentation were as described previously[13]. Measurement conditions; spectral window ± 20 kHz, data points 1,024 real, cross-polarisation time 1.5 ms, delay time 2 s, line broadening 50 Hz, scan numbers 21,000 for the DNA and 70,000–80,000 for the synthetic copolymer.

phosphates is pushed out on the surface of the duplex while the other is pushed into the major groove of the DNA, as judged from the general features shown by phosphate groups in the B and A form structures, respectively[4,6,7]. Therefore, the characteristic cleavage of the P—O(3′) bond of adenosine in poly(dAdT)·poly(dAdT) by pancreatic DNase I (ref. 19) may not actually be sequence-specific in a rigorous sense but rather the result of the difference in its accessibility to the enzyme. As a consequence, the upfield resonance is tentatively assigned to the phosphate of the ApT sequences and the downfield resonance to the phosphate in the TpA sequences.

Finally, we will consider the spectra obtained when fibres are orientated perpendicular to the applied magnetic field. To account for the perpendicular spectra, reorientational motion about the helical axis must be considered[13]. In principle, the perpendicular spectrum should display a doublet, assuming that the molecules are rigid and that all phosphodiester conformations are symmetrical with respect to the helical axis. The perpendicular spectrum for natural DNA exhibits a singlet (Fig. 2), which was interpreted previously in terms of rotational motion about the helical axis[13]. Furthermore, the line width of the parallel spectrum is broader by 10 p.p.m. than that of the perpendicular spectrum for this DNA as a result of the variation in phosphodiester orientation. The same considerations may be applied to the alternating polynucleotide. A rather asymmetrical singlet was observed (Fig. 2), whereas a doublet would be expected even with rapid rotational motion about the helical axis. By using the estimated individual line width (13 p.p.m.) the separation of the resonances, if any, for the perpendicular spectrum would be about 10 p.p.m. or less, so that the doublet appears as a broad singlet at the frequency used here, but would possibly be split at higher frequencies. The structural considerations from the NMR data on the phosphodiester group in this synthetic polynucleotide will be discussed in more detail elsewhere.

Table 1 ^{31}P NMR parameters obtained at 24.3 MHz from salmon sperm DNA and poly(dAdT)·poly(dAdT) fibres at different orientations to the magnetic field

	RH (%)	Rotation angle (deg)*	Chemical shift† σ (p.p.m.)	Line width (p.p.m.)
Na-poly(dAdT)·poly(dAdT)	98	0	−17.1 4.0	39
		90	5–13	29
Na-DNA‡	98	0	−5	42
		90	8	32

* Rotation angle of zero corresponds to a parallel orientation of the fibres to the magnetic field and 90° to a perpendicular orientation.

† Measured from trimethylphosphate as external reference; upfield is positive.

‡ Data from ref. 13.

X-ray structure of the ternary complex Zn(II)-ATP-2,2′-bipyridyl and possible model for ATP transport

P. Orioli*, R. Cini*, D. Donati† & S. Mangani*

* Istituto di Chimica Generale,
† Istituto di Chimica Organica dell'Università di Siena, Siena, Italy

Ternary complexes between metal ions, nucleotides and aromatic heterocyclic amines are being investigated by X-ray diffraction as possible models for enzyme–metal–substrate interactions[1,2]. Kennard and coworkers[3] have reported the crystal structure of the ATP disodium salt. Although more recently several crystal structures of binary and ternary complexes between metal ions and nucleoside monophosphates have been reported, no structure combining metal complexes with nucleoside di- or triphosphates has been reported. Most divalent metal ions catalyse the nonenzymatic transfer of phosphate from nucleoside polyphosphates to various acceptors[4]. Therefore, these compounds in water solution undergo extensive hydrolysis in the presence of metal ions, leading to the formation of the monophosphates; for instance, at *p*H 6.5, Cu^{2+} accelerates the hydrolysis of ATP by a factor of about 300 (ref. 5). We report here the crystal and molecular structure of the complex $[Zn(II)\text{-}H_2ATP\text{-}2,2'\text{-bipyridyl}]_2\cdot 4H_2O$, determined by single crystal X-ray analysis. The complex molecule provides a possible model for ATP transport and phosphate group transfer mechanism.

0028-0836/80/070691—03$01.00

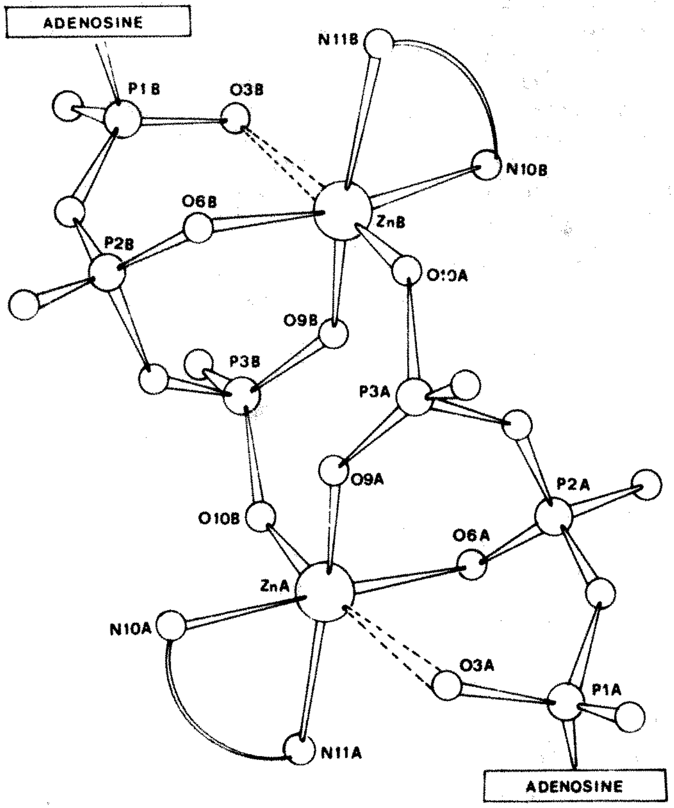

Fig. 1 Schematic drawing of the molecule, showing the mode of bonding of ATP.

Sigel and coworkers have shown that the presence of a second ligand possessing stacking capabilities (bipyridyl, phenantroline, tryptophan) greatly reduces the metal ion promoted dephosphorylation[6]. The inactivity towards hydrolysis is due to the formation of very stable ternary complexes between the nucleoside triphosphate, the metal ion and the second ligand. Stacking interactions between the heterocyclic base and the purine or pyrimidine moieties enhance the stability of the ternary complex[7].

We have been able to isolate microcrystalline compounds between ATP, 2,2′-bipyridyl and some 3d metal ions, such as Mn(II), Co(II), Cu(II), and Zn(II) in 1:1:1 ratio. These compounds are readily formed on mixing hydroalcoholic solution of Na_2H_2ATP and 2,2′-bipyridyl with an aqueous solution of the metal sulphates in equimolar ratio. On the basis of the analytical and X-ray results, the complexes can be formulated as $[M\text{-}H_2ATP\text{-}2,2'\text{-bipyridyl}]_2\cdot 4H_2O$. The solid compounds formed are essentially insoluble in most common solvents and only slightly soluble in water. Their X-ray powder patterns are very similar and only slightly soluble in water. Their X-ray powder patterns are very similar, minor differences being noted for the copper complex. Very small crystals, only for the zinc compound, were obtained on mixing dilute solutions of the reactants at *p*H 4. Trials to grow larger crystals failed, owing to the precipitation of hydrolysis products upon the crystals on standing.

X-ray diffractometer data were collected on one of these crystals with the following results: $a = 11.105(3)$, $b = 25.223(7)$, $c = 10.539(3)$ Å, $\beta = 91.34(4)°$, monoclinic, space group $P2_1$, with two dimeric units in the cell. Patterson and Fourier syntheses gave readily all the atomic positions, which were subsequently refined by least squares methods to an *R* factor of 9.8% over 1,617 reflections with intensity greater than twice their standard deviation.

The structure of the compound consists of dimeric molecules in which two zinc atoms are held together by two —OPO— bridges from the γ-phosphate groups of two ATP molecules, an arrangement which leads to the formation of an eight-membered puckered ring (Fig. 1). In the dimer both zinc atoms show a distorted octahedral coordination, formed by two oxygen atoms from different γ-phosphate groups, one oxygen atom from the β-phosphate group and the two nitrogen atoms of the bipyridyl ligand. The sixth position is completed by an α-phosphate oxygen atom which is only weakly bound, the ZnA–03A and ZnB–03B distances being respectively 2.70(4) and 2.42(4) Å. The other Zn–O distances average 2.02(3) Å and the mean Zn–N distance is 2.15(4) Å.

The structure is held together by strong intermolecular stacking interactions between bipyridyl and purine groups, and by

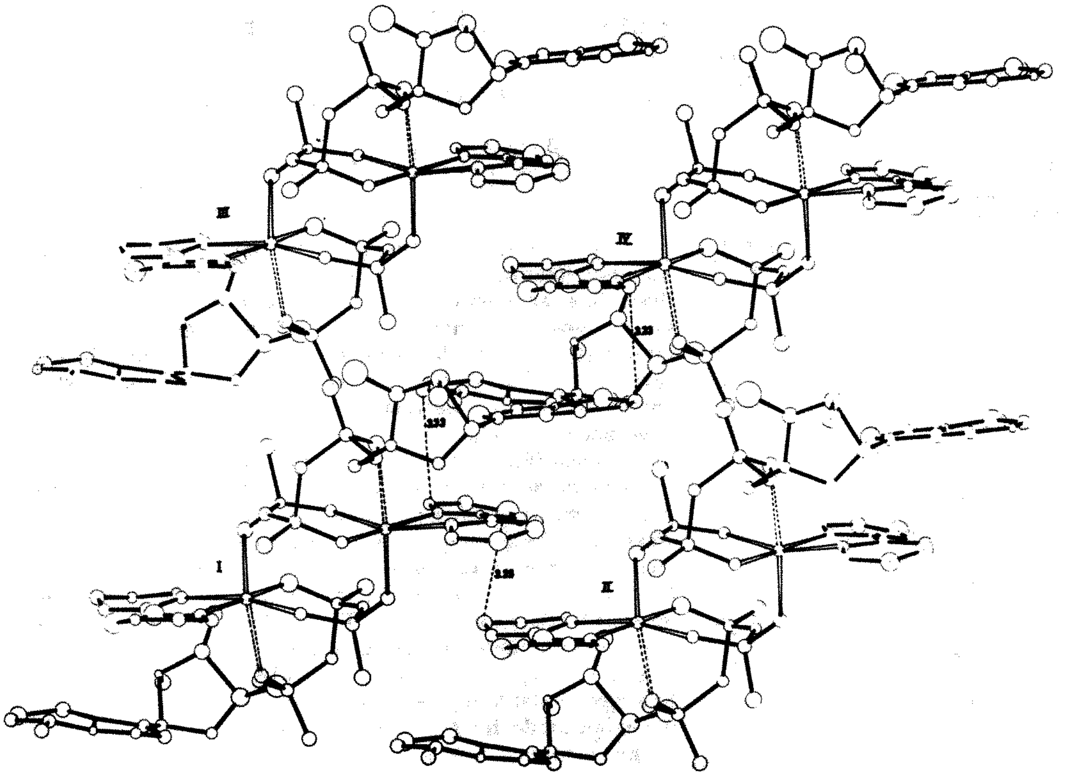

Fig. 2 Diagram of four dimeric units in $[Zn(II)\text{-}H_2ATP\text{-}2,2'\text{-bipyridyl}]_2\cdot 4H_2O$ showing the intermolecular stacking. Water molecules have been omitted for clarity. The molecules are in the following positions: I (*X*, *Y*, *Z*); II (*X* − 1, *Y*, *Z*); III (*X*, *Y*, *Z* + 1); IV (*X* − 1, *Y*, *Z* + 1). There are two types of stacking interactions: a bipyridyl–purine interaction and a bipyridyl–bipyridyl self stacking. The stacking sequence is the following (B, bipyridyl; P, purine): $-B_b(II)-B_a(I)-P_b(IV)$; $P_a(I)-B_b(IV)-B_a(III)-$; and so forth (a, b refer to the two monomers in the same dimeric molecules). The shortest distances in the stacking sequence are also shown.

hydrogen bonds between most of the polar groups. Water molecules appear to be disordered in the lattice.

Although one must be careful in drawing conclusions from the solid state, the present structure is in agreement with the results from the solution studies concerning the stability of ATP ternary complexes towards hydrolysis[7]: (1) the chelating bipyridyl does not allow interaction of the metal ion with N7 of the base moiety; (2) binding of the phosphate chain takes place essentially through the β- and γ-phosphate groups, the interaction with the α-phosphate being rather weak. Another feature arising from the solution studies is the stability enhancement due to intramolecular stacking between purine and bipyridyl. The present structure shows very strong stacking interactions between different molecules, as expected in a crystal, where intermolecular forces are much stronger than in solution (Fig. 2).

Finally it should be pointed out that the present structure also supports the mechanism proposed for the enzyme-catalysed transfer of the phosphoryl group from ATP[7]. In fact, shift of the metal ion along the phosphate backbone into β, α coordination leading to a labile γ-phosphate group, can be simply performed by a slight shortening of the Zn–03 bond and consequent loosening of the Zn–09 bond.

Bond lengths and angles and detailed conformational analysis of the molecule as well as physicochemical characterisation of all the four complexes will be reported elsewhere.

Recently, several genes coding for messenger RNA, transfer RNA and ribosomal RNA in eukaryotes have been found to be interrupted in their coding regions by DNA sequences which are not represented in the mature RNA transcripts (see ref. 1 for review). Many of these intervening sequences, or introns[2], are now known to be transcribed in the precursor RNA, from which they are subsequently processed out to form the mature RNA[3–10]. As the intron–exon junctions must in some way be recognised for accurate splicing, the nucleotide sequences of these regions from a number of protein-coding and tRNA genes have been analysed[11–18]. Sequence homologies were found at the splice points of the protein-coding gene introns from diverse organisms[12,13], but the tRNA intron boundaries were not similar to these[14,15]. This has led to the speculation that different splicing activities are necessary for the processing of introns in mRNA and tRNA precursors[19]. We report here the sequence of a ribosomal RNA gene intron from *Tetrahymena* in which intron–exon junctions differ from those analysed to date.

In *Tetrahymena pigmentosa*, restriction endonuclease mapping and electron microscopic analysis of R-loops[20], as well as recent S_1 nuclease mapping experiments (ref. 21 and J. Engberg, personal communication) have demonstrated that an intervening sequence is present in the macronuclear 25S ribosomal RNA genes of certain strains, but is absent from the rDNA in others. All the rDNA molecules of each strain are of one kind, either containing or lacking the intron, and intron-containing genes must therefore be functional. Recently, evidence from R-loop hybridisation has been used to show that such intervening sequences are indeed transcribed in the closely related species *Tetrahymena thermophila*[7,10]. Thus, the DNA sequences at the boundaries of the intervening element correspond to points at which the precursor rRNA must be spliced.

To study the intervening sequence in *T. pigmentosa* rDNA in more detail, the recombinant plasmids pTp6001 and pTp8002 were constructed from the vector pBR322, as described previously[20]. Briefly, pTp6001 contains a 1.6-kilobase *Hin*dIII fragment from the rDNA of strain 6UM, which includes a part of the 25S rDNA and the intron that interrupts it. Plasmid pTp8002 contains a 1.2-kilobase *Hin*dIII fragment that includes only the corresponding 25S rDNA of strain 8ALP, and lacks the intron. Restriction fragments from these plasmids were sequenced by the chemical cleavage method of Maxam and Gilbert[22]. Position and orientation of the 5′-labelled strands used are indicated in Fig. 1. The entire sequence of the 407-base pair intron and the surrounding rDNA is depicted in Fig. 2, which is a composite of the sequence data obtained from both pTp6001 and pTp8002. In those regions where both DNAs have been analysed (see Fig. 1), the nucleotide sequences are identical.

By directly comparing the sequence from pTp6001 with that from pTp8002, a distinct position is found at which the intron interrupts the coding region (Fig. 3). This is in contrast to all other intron–exon boundaries sequenced to date, in which the exact point of interruption is ambiguous due to the presence of directly repeated nucleotides at the junctions[12,13]. In precursor RNA from protein-coding genes containing introns, the position of the splice within the repeats has been proposed to occur such that all introns begin with 5′-GU and end with AG-3′ (ref. 13). The ends of the *T. pigmentosa* rDNA intron do not obey this rule, and furthermore, are completely different from recent model sequences proposed for mRNA-type intron–exon junctions[1,13,24]. In addition, these rRNA splice points bear no resemblance to the sequences from yeast tRNA intron boundaries[14,15]. At the *T. pigmentosa* rDNA intron junctions themselves, we note the presence of the sequence TCX|XAA at both the 5′ and 3′ ends; whether or not this has a role in defining the splice point in the transcript is unknown.

For recognition and accurate processing of an intron by a splicing mechanism, more information is necessary than is found in the short regions of nucleotide homology seen at mRNA intron boundaries. It is therefore likely that secondary structure of intron-containing precursor RNAs is also important for recognition of the regions where splicing is to occur. In this context, it is interesting that the *T. pigmentosa* rDNA intron itself is fairly rich in potential secondary structure, as determined by computer analysis and indicated in Fig. 2. We also note that both ends of the intervening sequence are rich in AT.

Recently, Allet and Rochaix[23] have determined the sequence of the boundaries of the intron in the *Chlamydomonas* chloroplast 23S ribosomal RNA gene. In this case, too, no similarity to either the mRNA or the tRNA intron junctions of nuclear genes is present. As we have found in *T. pigmentosa* rDNA, the ends of the *Chlamydomonas* rDNA intron are unequivocally defined. Although some sequence homology between these two rDNA introns can be found, any speculations on a model sequence for rRNA intron–exon junctions must await the analysis and comparison of other intron-containing nuclear and organellar rDNAs. If, however, the differences in the splice point sequences of tRNA and mRNA introns reflect a difference in

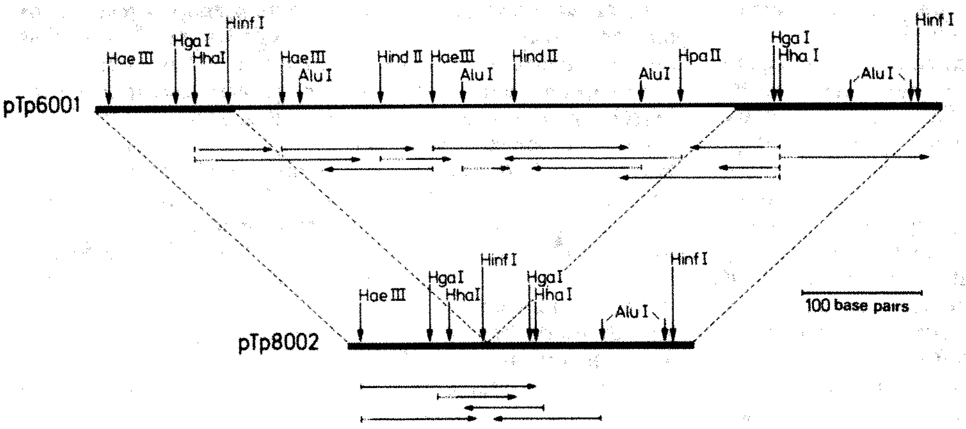

Fig. 1 Partial maps of clone pTp6001, which contains a rDNA intron, and clone pTp8002, which lacks this intron. The connecting lines show the regions of homology between these two clones. All restriction sites are given for those enzymes which were used to prepare fragments for sequencing. Horizontal arrows below each map indicate the position, direction and length of sequence determined for each fragment. After 5′-end-labelling with [γ-^{32}P]ATP and T4 polynucleotide kinase, fragments were strand separated in 0.1 M KOH and 1 mM EDTA, or were digested with a second restriction enzyme, and were then subjected to electrophoresis on 6% or 10% acrylamide gels. DNA sequencing was carried out using the chemical cleavage technique of Maxam and Gilbert[22] with minor modification. The degraded strands were separated on 10%, 20% or 24% acrylamide, 7 M urea gels (2.5 × 200 × 400 mm). After autoradiography, the nucleotide sequences derived from each fragment were stored by computer and analysed for overlaps with each other.

Fig. 2 Sequence of the 407-base pair rDNA intron and adjacent regions. The sequence presented is a composite of both clones pTp6001 and pTp8002. Only the strand which corresponds to the ribosomal RNA is shown. The intron–exon transition points are indicated by arrowheads; exon regions are underlined. About 100 base pairs of the exon regions were analysed for both clones and were found to be identical. The recognition sites of restriction endonucleases used in the sequence analysis are overlined: AGCT (*Alu*I), GGCC (*Hae*III), GACGC (*Hga*I), GCGC (*Hha*I), GTCAAC (*Hind*II), GACTC (*Hinf*I), CCGG (*Hpa*II). The sequence was screened for potential secondary structure by a computer search for inverted repeat sequences. Only those inverted repeats which are less than 15 nucleotides apart from each other, such that they might form hairpins, are indicated by head-to-head arrows. The inclusion of G·T base pairs, in addition to G·C and A·T base pairs, has been allowed in the inverted repeats. Computer programs used were developed by G. Osterburg and R.S. (unpublished).

MATTERS ARISING

Problems with mesospheric electric field measurements

HALE AND CROSKEY[1] have recently reported some unusual results regarding the mesospheric fair weather electric field. These results are extremely interesting for two reasons: the reported values of the electric field are much larger at all altitudes than those previously reported, and the field is observed to increase dramatically at $\sim$65 km altitude. There are several reasons why we feel that the reported data should not be interpreted in the straightforward way proposed by Hale and Croskey, but the possibility that their result is correct certainly justifies considerable further work in this area.

We have performed similar experiments, two of which have been reported[2]. We drew two conclusions from our results. First, the experiment is an extremely difficult one, with large anomalous charging events of both sign seriously and frequently perturbing the potential of the central payload with respect to the medium as determined by the common mode variation of several $\gtrsim 1$ m long antennas. Comparison of these results with unpublished night-time results suggests that the photoelectric effect is not responsible for the observed potentials.

On the basis of body-mounted Gerdien condenser data, Hale and Croskey assert that the potential of their payload did not vary significantly during flight. However, a Gerdien condenser only measures the potential of the payload with respect to the gas passing through the condenser. Essentially all measurements that have been made with extended antennas of the potential of moving vehicles in the 20–80 km altitude range show large, rapidly varying potentials (ref. 2 and personal communications from F. S. Mozer, R. H. Holzworth, and L. C. Hale). On the other hand, Gerdien condenser payload potential measurements seem to show this sort of effect relatively seldom[1,3]. These contrasting results strongly suggest that the potentials seen by the long antenna measurements are being developed sufficiently far from the payload to fool the Gerdien condenser. Gas or ion entrainment effects inside the Mach cone may also be confusing the issue. The fact that large detached potential drops[4–8] and ion entrainment effects[9] have been observed in other admittedly disparate experimental circumstances suggests that similar effects are possible in this case. Regardless of the actual mechanism responsible, a rigorous, physically detailed explanation of the discrepancy between probe and condenser measurements of payload potentials in the mesosphere must be presented by Hale and Croskey (or others) before their measurements can be believed. Cryptic allusions to accumulated experimental experience are no substitute for sound physical argument.

Second, we detected an electric field of 20 mV m^{-1} at an altitude of $\sim$70 km in fair weather, during magnetic quiet, at White Sands, New Mexico, a low latitude site. This measurement was made during a period when the central payload was not anomalously charged. Our experiment and the Hale and Croskey experiment used identical input amplifiers, and were very similar in geometry. Taken together, the measurements imply that Hale's hypothetical global mesospheric circuit must, in fact, be confined to high latitudes or the nightside, or both. This conclusion, and Hale's conclusion that the mesospheric circuit has 'holes' opened in it by auroral activity, has serious observable consequences. The horizontal fringing fields produced at the edges of the 'holes' and the southern edge or the terminator edge of the circuit would be observable at balloon altitudes. Hale *et al.*[3] suggested that the critical observations have been suppressed because balloon observers tend to attribute all data taken during periods of inverted vertical fields to electrified clouds. However, for the case reported by Hale and Croskey, these horizontal fields would not be accompanied by an inversion of the vertical field. Hundreds of hours of balloon data have been taken under circumstances where the fringing fields should have been seen, and they have not been observed (personal communications from F. S. Mozer, and R. H. Holzworth)[3,4]. More important, good agreement is regularly reported between balloon and ionospheric measurements of the horizontal electric field[10,11]. This agreement argues strongly against the existence of these fringing fields, and hence of the hypothetical mesospheric circuit.

A final criticism of both the Hale and Croskey results and the Bragin *et al.*[12] results concerns vehicle dynamics. The large field peaks reported by both groups occur when the payload is travelling at a velocity greater than or equal to Mach 1, and is passing through the region of maximum aerodymamic deceleration. In this context, anomalous 'field values' are not remarkable. What is remarkable is that there are any non-anomalous results from this region.

We would like to stress that there are good physical reasons for knowing the mesospheric electric field[1,2] and the properties of the mesosphere. The points of controversy raised here cannot be resolved without extensive further work, involving parallel approaches, and experiments with controls and comparisons.

HALE REPLIES—Although Bering, Benbrook, and Sheldon do not only respond to our letter but also to statements made elsewhere, they have, nevertheless, raised questions that need to be resolved before problems of electrical coupling through the atmosphere can be solved.

We described a quiet-to-disturbed enhancement in the lower atmosphere vertical electric field accompanied by a decrease in a large mesospheric field. The idea of a 'global' mesospheric circuit, possibly related to an aerosol layer, was one suggestion made to explain this effect and the USSR data[1].

We have performed additional measurements which show other aurorally related effects, including field reversals (suggestive of earlier observations by Freier[2] and by Olson[3]) and large amplitude ($\sim$100%) wave-like structure in the lower atmosphere field (L.C.H., C. L. Croskey, and D. F. Young, in preparation). These effects cannot obviously be explained by 'classical' theory, by 'mapping' of magnetospheric fields, or by a simple constant altitude 'global' mesospheric circuit. A mid-latitude sunrise measurement (16 September 1979, 05.30–07.18 LT, Wallops Island, Virginia) showed a relatively low and featureless electric field below 65 km, increasing to about 1.5 V m^{-1} downwards at 20 km, the value measured by Bering *et al.*[4]. The obvious absence of 'anomalous charging' effects on this measurement, where the vehicle potential was determined by a simple 'blunt' probe'[5] in the front surface, gives us confidence that our high latitude results are real, as the vehicle velocity profiles were similar.

0028-0836/80/070695—02$01.00

Thin linear electrodes parallel to the flow would seem to be superior to plates or spheres for electric field measurements when dominated by a continuum flow. A wire or rod of length L can be shown to have about the same conductance to the medium as a sphere of diameter L but will have far less photo-emission or turbulent wake effects. Plate electrodes would be sensitive to angle-of-attack variations.

Only a small fraction of the "hundreds of hours of balloon data" cited by Bering *et al.* were accompanied by simultaneous measurements of the auroral electric field, and when they were the agreement was not always good even during fair weather[6]. The limited extent of 'fringing fields' of even a non-global mesospheric circuit would be such that I doubt whether there is sufficient data to reject such a possibility out-of-hand, although this is not necessarily the only coupling mechanism. The local effects of aurorally produced charge separation, suggested by Freier[2], would apparently be capable of explaining some of the observations, particularly the reversals.

I echo Bering *et al.*'s plea for the acquisition of more data 'with controls and comparisons'. Perhaps this can be done by the international community during the forthcoming Middle Atmosphere Program (MAP). The several hundred meteorological class rockets necessary for a reasonable global description of the electric field in a variety of geophysical conditions is a minute effort compared to the tens of thousands of rockets that have been launched to acquire mesospheric wind and temperature data. These measurements should certainly be accompanied by balloon measurements but note that our coupling effect would not have been detected at intermediate altitudes.

GABAergic mechanisms in the substantia nigra

MARTIN AND HAUBRICH[1] have confirmed the original reports[2,3] of contralateral rotational behaviour following unilateral injections of the γ-aminobutyric acid (GABA) agonist muscimol into the zona reticulata of the rat substantia nigra. They have also confirmed a previous report[4] that intranigral perfusion of muscimol increases ^{3}H-dopamine (DA) efflux in striatal perfusates loaded with radiolabelled DA precursor. We believe their conclusion, that contraversive rotation to intranigral muscimol is mediated via activation of nigrostriatal DA neurones, to be erroneous.

Unilateral intranigral injections of muscimol ($100\ \text{ng}\ \mu\text{l}^{-1}$ saline) were made[2] into the substantia nigra of unlesioned rats or of rats in which the ipsilateral nigrostriatal DA system had been destroyed 21 days previously by intracerebral injection of 6-hydroxydopamine (6-OHDA $8\ \mu\text{g}$ per $4\ \mu\text{l}$) into the medial forebrain bundle[5]. Rotational behaviour was quantified in automated rotometers[5] for 45 min and animals then taken for neurochemical analyses. 6-OHDA-lesioned rats with 90% destruction of the nigrostriatal DA system, as indexed by striatal tyrosine hydroxylase activity, exhibited vigorous contralateral rotation to intranigral muscimol that was indistinguishable from that shown by nonlesioned rats (Fig. 1). We therefore conclude that these circling responses are independent of dopaminergic mechanisms. Note that there is already evidence that nigral non-dopaminergic neurones control postural asymmetry[6], and that Martin *et al.*[7] were unable to demonstrate consistent antagonism of muscimol-induced turning by haloperidol. We find doses of haloperidol that are clearly blocking striatal DA receptors to have either very weak or no effect on rotational responses after intranigral administration of GABAergic drugs[8].

In unlesioned rats, striata ipsilateral to intranigral injections of 100 ng muscimol showed[8] elevated concentrations of DA (+98%, $P<0.02$) and of the intraneuronal[9] metabolite dihydroxyphenylacetic acid (+71%, $P<0.01$) but not the extraneuronal metabolite[9] homovanillic acid (+4%, NS). This neurochemical profile is consistent with that of the increased synthesis and decreased release of DA which follows inhibition of impulse flow in nigrostriatal DA neurones[10], and therefore with a GABAergic inhibition of activity of nigral neurones[11]. The finding by Martin and Haubrich[1] of elevated ^{3}H-DA in striatal perfusates following intranigral muscimol could in part reflect the elevated synthesis of DA known to occur after inhibition of impulse flow in nigrostriatal DA neurones[10].

Rotation after intranigral muscimol is most enduring and rats taken for neurochemical studies at 45 min after such treatment were rotating vigorously at this time. The resultant striatal neurochemical profile was consistent with reduced dopaminergic activity. In their reply Martin and Haubrich concede that DA release may be reduced at 45 min after intranigral application of muscimol, when rats would still be rotating. This is inconsistent with their proposition that striatal DA release mediates the contralateral rotational response to intranigral muscimol. We have recently shown[12] that destruction of striatal cell bodies and striatal efferents by intrastriatal injections of kainic acid fails to attenuate turning following intranigral muscimol. Therefore striatal DA release cannot mediate this response.

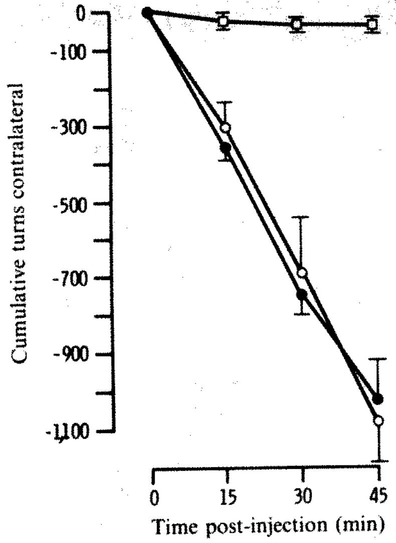

Fig. 1 Rotational responses to unilateral intranigral injection of 100 ng muscimol in male Sprague–Dawley rats with (○, $n = 5$) and without (●, $n = 10$) destruction of the ipsilateral nigrostriatal DA pathway induced with 6-OHDA. Intranigral injections were made under light ether anaesthesia as previously described[2], in $1\ \mu\text{l}$ saline. 6-OHDA ($8\ \mu\text{g}$ per $4\ \mu\text{l}$ saline ascorbate) was injected 21 days previously into the medial forebrain bundle[5]. Control animals received $1\ \mu\text{l}$ saline into the nigra after 6-OHDA lesions (□, $n = 5$); such injections made into the nigra of unlesioned animals also induced negligible circling[2]. Rotational behaviour was quantified in automatic rotometers[5].

Thus our behavioural findings suggest that contralateral rotation following intranigral injection of GABAergic drugs is not due to activation of the nigrostriatal dopamine system and our neurochemical findings suggest that the activity of this system can be inhibited by this procedure[13].

MARTIN AND HAUBRICH REPLY—We have reported that the efflux of ^{3}H-dopamine (DA) from the ipsilateral striatum increases during contraversive turning evoked by the intranigral infusion of muscimol in the rat. From these data we suggested that the release of striatal DA may mediate the muscimol-evoked contralateral turning[1]. In a separate study using immobilised cats, Cheramy and coworkers have also demonstrated that the intranigral infusion of muscimol elicits a similar efflux of ^{3}H-DA from the ipsilateral striatum[2,3]. The results from both studies indicate that dopamine release occurs in the ipsilateral striatum during the intranigral infusion of muscimol. We feel that our interpretation of the push–pull data are correct.

Waddington has challenged our suggestion that the release of DA might mediate muscimol-induced turning. This finding is based on two of his observations. First, the destruction of 90% of the striatal DA neurones with microinjection of 6-hydroxydopamine (6-OHDA) into the medial forebrain bundle did not attenuate the turning evoked by the application of muscimol into the substantia nigra. Although the seeming complete lack of diminution in muscimol-evoked turning in 6-OHDA-treated animals is somewhat surprising, it does not preclude the possibility that the remaining 10% of the DA neurones might mediate the turning, especially in view of the supersensitivity which develops in postsynaptic DA receptors after 6-OHDA treatment[4]. Therefore, this negative finding does not incontrovertibly exclude the possibility that muscimol causes turning by stimulating DA release. Waddington has apparently not determined whether or not DA release occurs in the striatum of the 6-OHDA-lesioned rats following the intranigral microinjection of muscimol, nor whether haloperidol depresses significantly the muscimol-induced turning in 6-OHDA-lesioned rats as in intact animals[5–7], and therefore these data are not conclusive in ruling out the role of dopamine release in the turning activity evoked by intranigrally applied muscimol.

Waddington also suggests that muscimol inhibits the release of DA, whereas we have reported an enhanced DA release. Our conclusion is based on direct measurement of DA release from dopaminergic neurones during the time of the muscimol infusion, whereas those of Waddington are based on indirect evidence obtained from measurement of levels of DA and metabolites in tissue dissected 45 min after the microinjection of muscimol. We feel, therefore, that there is no basis for comparing the two dissimilar pieces of information and that to debate the point is meaningless. We feel strongly that we are measuring DA release.

As haloperidol only partially antagonised the muscimol-evoked turning in another study[5], we postulated the possible activation of at least one other neuronal system, perhaps GABA-like, in the activation of the muscimol-evoked turning. We did not wish to imply that DA release is the sole mediator of the turning. Contrary to Waddington's assertion, however, we feel that our evidence is quite compelling in indicating that striatal DA release, at least in part, may mediate the turning induced by intranigrally applied muscimol.

Is corticotropin releasing factor modulated vasopressin?

A RECENT report by Gillies and Lowry concludes that corticotropin releasing factor (CRF) is arginine vasopressin (AVP) modulated by other hypothalamic factors[1]. This claim is based on several experimental observations. First, fractionation of a crude extract of stalk median eminence (SME) showed that three factors were required for full biological activity. Second, on Biogel P2, the major peak of CRF activity eluted in the expected position for AVP. Third, removal of AVP by cross-reacting the SME extract with vasopressin antisera dramatically reduced the CRF activity. Finally, SME extract from Brattleboro rats, which lack AVP genetically, contains 20% of normal CRF activity.

Our laboratory has also published evidence that the CRF activity of SME extract contains at least two factors which are required for full CRF activity[2]. Furthermore, on the basis of studies of the CRF-like activity of peptides related to oxytocin and vasopressin, we showed that the greatest CRF-like activity was displayed by AVP, in which 40 ng contained 27% of the CRF-activity of one median eminence[3]. However, because we observed normal CRF-like activity in a SME extract of DI-HOMO (Brattleboro) rats, we discarded the notion that AVP is the physiological CRF. On the basis of this evidence, we have proposed previously that the structure of CRF may closely resemble that of AVP.

Because our data comparing the CRF-like activity of Brattleboro SME extract with that of normal rates have not yet been published, we repeated these experiments in our laboratory. We used a semi-automated *in vitro* bioassay for CRF in which the ACTH released from normal rat pituitary halves is determined by measuring the corticosterone secreted by normal rat adrenal quarters in an automated superfusion system[3]. This bioassay has a linear dose–response relationship at 0.05–2.0 median eminence equivalents.

Median eminence extract from normal Long–Evans, normal Sprague–Dawley and DI-HOMO Brattleboro rats was prepared in 0.1 M HCl at a concentration of 25 µl per SME[4]. The test dose in all experiments was 20 µl, 0.8 SME equivalents, which was well within the linear portion of the dose–response curve for this bioassay[3]. After a 2-h preincubation, one set of each pair of pituitaries was incubated for 1 h with 20 µl of SME extract from Sprague–Dawley rats; the second set of each pair of pituitaries was incubated in buffer alone to serve as a control. After a second preincubation of 1 h, the test sample was incubated with one set of each pair of pituitaries; again, the other set served as a control. ACTH released by the pituitary halves, as well as any ACTH-like activity in the SME extract, was measured in a continuous flow, automated, *in vitro* superfusion apparatus containing adrenal quarters. This assay is described in detail in ref. 3.

Stalk ME extract of Brattleboro rats ($n = 7$) contains 98% (±s.e., 12) of the CRF-like activity of normal Sprague–Dawley rats ($n = 6$) and 96% (±s.e., 12) of that of normal Long–Evans rats ($n = 4$). Therefore, we conclude that Brattleboro rats, which lack AVP and its associated neurophysin[5–7], contain essentially normal amounts of hypothalamic CRF activity, and, presumably, normal amounts of CRF. The only other published observation which shows a dramatic reduction (~60%) of CRF-like activity in SME extract from Brattleboro rats uses a dispersed cell pituitary assay system[8], as do Gillies and Lowry. All workers seem to agree, however, that the Brattleboro rat can respond to stress with the secretion of near-normal levels of corticosterone[8–10]. Watkins observed a positive immunoperoxidase staining reaction in the paraventricular and supraoptic nuclei of Brattleboro rats when anti-[8-lysine]-vasopressin serum was used[11]. Lutz-Bucher *et al.* have concluded that the anterior pituitary contains receptor sites for vasopressin which are distinct from those for hypothalamic CRF[12]. In this context, it is interesting that Zimmerman has reported immunological evidence for another peptide in Brattleboro rats which cross-reacts weakly with anti-vasopressin[13] and may be related to the physiological CRF.

GILLIES AND LOWRY REPLY—The above response to our paper[1] describes an experiment in which no difference was observed between the CRF activity of Brattleboro hypothalmic extracts and that of normal rats. As Brattleboro rats are deficient in vasopressin (VP), the authors conclude that VP is not CRF. However, our recent work with extracts of stalk-median eminence (SME) from Brattleboro rats[2] has added support to our idea that CRF is modulated VP. We found that Brattleboro SME contained approximately one fifth the CRF activity found in normal SME. Similar observations have been made using both isolated pituitary cells[3] and pituitary quarters[4].

Gel filtration of Brattleboro SME revealed only two small discrete peaks of CRF bioactivity corresponding in position and size to the Vo and Ns peaks found after chromatography of normal rat SME[1]. The third and major CRF peak found in normal rat SME, which coelutes with synthetic AVP and resembles AVP in our immunoassay and CRF bioassay, was absent from the Brattleboro chromatogram. Furthermore, addition of synthetic AVP in amounts equivalent to that found in normal SME (10 ng AVP per SME[5]) to extracts of Brattleboro SME completely restored the CRF activity to that of normals[2]. This observation has now been confirmed in a different assay system[4]. These results coupled with the facts that (1) we have consistently been able to combine the Vo and Ns CRF peaks from the chromatogram of normal SME with either the major AVP-CRF peak or equivalent amounts of synthetic AVP to restore full CRF bioactivity[1] and (2) no analogue of VP has been found with CRF bioactivity greater than AVP[5,6], suggest to us that we have ample support for our conclusion that the AVP-CRF peak is true vasopressin, and not merely related in structure to it.

The above response cites Zimmerman's preliminary observation on the possibility of a vasopressin-like peptide in the Brattleboro rat which may be related to CRF. In a subsequent report[7], however, it was stated that homozygous Brattleboro rats lack VP and its associated neurophysin and the occasional staining of some cells in the SON and PVN of these rats with their antiserum to AVP "appears to be due to slight reactivity of this antiserum to oxytocin". It should also be noted that the antiserum used by Watkins[8] had 14% cross-reactivity with oxytocin and (8-arginine)-VP, so one cannot exclude the possibility of a positive immunohistochemical reaction in the SON and PVN of homozygous Brattleboro rats being due to oxytocin.

The immunocytochemical studies of Stillman *et al.*[9], showed that VP and its associated neurophysin are stimulated by adrenalectomy, and their content in pathways to the portal capillaries is regulated by glucocorticoids, suggesting an important role for VP in corticotropin release.

As Pearlmutter *et al.* state above, all agree that Brattleboro rats are able to respond to stress. However, results of *in vivo* experiments are contradictory as to whether this stress response, as measured by adrenal activity, is normal[10] or significantly subnormal[11-13] and, if an abnormality exists, whether it is at the hypothalamic, pituitary or adrenal level. We feel that many of the contradictions from *in vivo* experiments could be clarified, and a truer measure of CRF release in response to stress would be made, if ACTH release were the parameter measured, because supramaximal stress stimuli may lead to the release of CRF (the non-VP components in Brattleboro rats) and consequently ACTH, in amounts exceeding those necessary for maximal stimulation of the adrenal glands. This could explain why Yates *et al.*[12] observed that a deficiency in the stress response of homozygous Brattleboro rats was evident only when submaximal stresses were investigated.

We also suggest that the bioassay system used in *in vitro* experiments contributes to this controversy on the role of VP as a CRF. First, isolated cell systems in general, and especially the perfused isolated cell system, as bioassays for CRF are far more sensitive than those using pituitary halves or quarters [we were able to demonstrate a threefold potentiation of 0.025 Brattleboro SME per ml by 0.25 ng AVP per ml (ref. 2)]. This must account for the fact that we were able to observe discrete peaks of CRF bioactivity in the chromatogram of extracts of small numbers of rat SME, and identify one peak as VP[1]. Second, fresh excised rat anterior pituitaries contain significant amounts of VP[15] which disappear from the tissue only after incubation for 3 h, suggesting specific binding to receptors. Therefore, in bioassays which use freshly removed tissue or incubated tissue which has been previously stimulated with solutions containing VP, such as a hypothalamic extract (as in the bioassay system used by Pearlmutter *et al.*[6]), it is possible that no difference would be found between the CRF activity of Brattleboro and normal rat SME, as the VP component of CRF would already be in the tissue. It is interesting to note here that Buckingham and Leach[4], who use a CRF bioassay involving rat anterior pituitary quarters coupled with the cytochemical bioassay for ACTH[16], have reported diminished CRF bioactivity in Brattleboro SME. As well as the difference in the ACTH bioassays used, the discrepancy with the findings of Pearlmutter *et al.* may be due to the duration of static incubation of extracts with anterior pituitary tissue—15 min for Buckingham and Hodges[16] and 60 min for Pearlmutter *et al.*[6], compared with 2–3 min contact of stimuli with isolated cells in our perfused system. The net CRF bioactivity observed could depend on the breakdown of both CRF and ACTH in the incubation medium.

BOOK REVIEWS

What the tortoise never said to Achilles*

Pure Chemistry Library
SCIENCE COLLEGE
[illegible] Upper Circular Road
CALCUTTA

Oliver Penrose

Gödel, Escher and Bach: An Eternal Golden Braid — A Metaphorical Fugue on minds and machines in the spirit of Lewis Carroll. By D. R. Hofstadter. Pp.777. (Basic Books: New York, 1978; Harvester: Brighton, UK, 1979.) $18.50; £10.50.

ACHILLES had overtaken the Tortoise, and had seated himself comfortably on its back. "So you've got to the end of our race — er, our book" said the Tortoise. "Even though it DOES consist of an infinite variety of self-referring statements, curious puns, paradoxes, and speculations? I thought some wiseacre or other had proved that the thing couldn't be done?"

"It can be done", said Achilles. "It HAS been done! *Solvitur legendo*. You see each pun or paradox only took HALF as long to read as the one before; and so . . ."

"But the Index", interrupted the Tortoise, "how did you finish THAT? Every time you came to the entry 'Achilles: mapped on to ant colony 318, 324' you surely had to turn back to the middle of the book, so how could you EVER finish?"

"That splendid index", murmured Achilles. "It's true I did have some trouble getting past the entry 'Zen Buddhism; computers and, 625 — 26' especially as one of the chapters is based on Zen kōans, but even so I'm sure I'd have beaten you if I hadn't spent so long trying to do that fascinating MIU puzzle in chapter 1".

"Oh yes", recalled the Tortoise, "given the string of letters MI, and the rules for producing new strings:

1. If your string ends with I, you can add a U at the end.
2. If your string is Mx, where x is any string, you can change it to Mxx.
3. If your string contains the sequence III, you can replace that sequence by U.
4. If your string contains the sequence UU, you can delete that sequence.

can you produce the string MU?"

"Well, I'm only a simple warrior", said Achilles "and I never did manage to produce MU, but I thought the puzzle was a BRILLIANT way of introducing the idea of a formal logical system."

"And formal logical systems are very important", said the Tortoise, "because the centrepiece of the book is a sketch of the proof of Gödel's theorem: that practically any formal logical system contains statements which can't be either proved or disproved within the system."

"Ah yes, that proof of Gödel's theorem", sighed Achilles. "Very entertaining, like the rest of the book, but even after reading it an INFINITE number of times I still don't think I understand it."

"Each reading taking only half as long as the previous one, of course", mused the Tortoise. "But I think the author's intention was not so much to give a crystal-clear explanation of Gödel's proof (he might possibly have done that better by making more use of Cantor's diagonal construction) as to exploit the idea of self-reference to the full. So he gives, as an analogue of Gödel's undecidable formal proposition, the following English statement: 'yields falsehood when preceded by its quotation' yields falsehood when preceded by its quotation."

"That must be the grandmother of all confusing self-referring sentences", said Achilles, mopping his brow. "I never DID manage to decide whether that one is true or not. But rather than get worried about it I turned to the Escher lithographs which he uses so delightfully to illustrate many of his ideas — for example, the picture of someone in an art gallery looking at a picture of a town which contains an art gallery which contains . . .".

"Do you mind", interrupted the Tortoise, "you are sticking your sword into my foot."

"MIND?", said Achilles, waving the sword excitedly. "That's just the kind of thing the rest of the book is about. What is a mind? Where is meaning located? How is knowledge represented? Can a computer be conscious? Can animals with very primitive nervous systems be said to think? . . ."

"More easily than featherbrained warriors", muttered the Tortoise testily.

"Do you remember the description in the book of Terry Winograd's artificial intelligence device SHRDLU," went on Achilles, as if the Tortoise had not spoken, "which can move solid objects around in response to commands like 'find a block which is taller than the one you are holding and put it into the box'?"

"With comments by 'the newly developed human being, Dr Tony Earrwig' who seems to be related in a mixed-up way to SHRDLU's creator" added the Tortoise. "By the way, if you had to read the chapter about Gödel's theorem so often, I'm amazed that you finished the book so quickly."

"Well, I have to admit", said Achilles, "that to help me catch up with you, I only read every other chapter. The book still seemed to make sense though."

"What?" The Tortoise was horrified. "You missed the best part. Those chapters are all about US. And you missed my wonderful invention, the Tortoise property, enjoyed by every number that is the difference of two primes".

"Are you sure you don't mean the Goldbach property, which is that the number is the SUM of two primes?"

"No, the difference. The Goldbach property is VERY dull: you can always tell in a finite number of steps whether a given number has it or not, whereas if a number does not have the Tortoise property you could go on trying primes for ever. Besides that", continued the Tortoise, "you missed some extremely ingenious dialogues, which are verbal imitations of contrapuntal devices used by Bach in his much-loved works such as the Musical Offering. They provide welcome points of relaxation between the more serious chapters that you did read."

"With Bach as a model, the book must be even better constructed than I thought", said Achilles. "And the author's enthusiasm certainly carries you along as you read. But don't I see our mixed-up relatives Les Cahil and Sir Otto E. over there? Let's go and join them". ☐

Oliver Penrose is a Professor of Mathematics at the Open University, Milton Keynes, UK.

Interferometric spectroscopy

E. R. Pike

The Principles of Interferometric Spectroscopy. By John Chamberlain. Pp. 347. (Wiley: Chichester, UK, 1979) £20.

THIS book is the result of the completion, collection and revision (to include up-to-date advances, by Chantry and Stone) of material left at the time of John Chamberlain's death in 1974. It represents an attempt to bring together the whole field of interferometric spectroscopy at a practical working level in a single self-contained and readily accessible fashion.

As a knowledgeable and able practitioner Chamberlain leads authoritatively from the work of Michelson through a historical introductory chapter to an exposition of introductory theory in chapters 2, 3 and 4. These three chapters cover the ground of the Fourier transform, sampling theory and related topics, the mathematical description of the light field, including the concepts of the analytic signal, coherence and the coherency matrix, and the theory of the practical interference function. The fast Fourier transform is treated in the book's final chapter. Much of this didactic material is, of course, readily available on the bookshelf but as presented here forms a particularly thorough and logical operational approach. A few purist quibbles can be raised here and there as, for example, on page 73 where it is stated that "Physically, the electric and magnetic wave-fields are real quantities . . .". Are they? In this book the only signals implicitly used are photon annihilation rates at the detector. If we were to measure an electron detection rate, say, in another branch of physics, would we assert that they derived from a real Schrödinger wave?

The theory of transform spectroscopy forms the core of the text in chapters 5, 6 and 7. Here are treated, respectively, the measurement of spectral line-shapes from the visibility curves, then non-dispersive and finally dispersive spectroscopy. Again, as in the previous section, the work is notable for its thoroughness and logical development. Full details are given of the effects and practical methods of dealing with them of truncation, sampling and phase errors. Apodisation schemes, for example, are reviewed in considerable detail.

A general information-theoretic approach is absent. The Fourier transform is taken for granted to be the magic requirement to derive what went in from what came out. The method of interferometric spectroscopy, however, is an ill-conditioned first-order Fredholm problem and thus insoluble without a 'model' for the inversion to inject sufficient extra *a priori* information to remove the ill-conditioning. The Fourier transform, viewed in this light, performs a least-squares fit to a model spectrum consisting of a truncated sum of cosine waves. Although this provides an extremely practical approach to retrieving such information about the spectrum as is transmitted by the instrument it surely does not squeeze out the last drop, and a discussion on these more general lines would have been interesting.

A competent chapter 8 is devoted to various experimental considerations such as finite apertures, imperfect mirrors, modulation schemes and rapid scanning. Perhaps in experimental matters the rival book of R.J. Bell (*Introductory Fourier Transform Spectroscopy*, Academic Press, 1972) is more extensive.

The importance of interferometric spectroscopy derives in large part from the so-called Fellgett advantage, and it was a disappointment to the reviewer to find, yet again, both in the introductory chapter and in chapter 9 on noise, the commonly propagated fallacious explanation that the improvement is due to seeing all components of the spectrum at once. To a mathematician the nature of a function does not change in its Sturm-Liouville transform and one would naturally ask why the grating is not superior because it sees all delay times at once! This (in his own words) "difficulty in navigating the trickier fine points" shipwrecks him on the erroneous conclusion (page 263) that a multiplex advantage does not exist in the photon noise-limited region, although, apparently without its relevance fully sinking in, the result of Kahn (correct within a factor of 2) is given on page 302. He founders also on page 299, getting completely wrong the intensity and photoelectron fluctuations for quasi-monochromatic light. "Gaussian" and "Bose-Einstein" should be replaced by "negative-exponential" and "geometric" in this discussion.

Apart from these blemishes, the first of which seems to be indigenous to the subject, the book can be recommended to anyone entering this field, even at the specialist price of £20. ☐

E.R. Pike is Deputy-Chief Scientific Officer in the Physics Group of the Royal Signals and Radar Establishment, Great Malvern, UK.

Small mammal ecology

Ian Linn

Ecology of Small Mammals. Edited by D.M. Stoddart. Pp. 386. (Chapman and Hall: London, 1979.) £15.

THIS book is an interesting and worthwhile attempt, in a series of essays by specialist authors, to review the state of the art in small mammal ecology and to indicate the areas in which this field of study still requires more intensive investigation. As a review it succeeds quite well. The individual essays reveal, in their expertise, the undoubted skill of the authors in their special fields, and the general coverage makes the whole exercise useful. Nevertheless, there is a lot of bias in this coverage, and it seems to me that the Editor might have exerted more discipline on his contributors, to ensure that the subject was dealt with more evenly.

Thus, the emphasis of the book is firmly laid on the ecology of the rodents of north temperate regions. This emphasis is a simple reflection of the animals and regions about which most is known, but the Editor on the first page of his preface defines small mammals as those weighing less than 5 kg, and there are plenty of insectivores, carnivores and lagomorphs in that category, some smaller primates and even a few artiodactyls. There are honourable mentions of some of these here and there, and a couple of special chapters devoted to bats and marsupials, but more is known than would appear from the text. Even in the case of rodents, which are well covered on the whole, the special problems of tropical animals receive less attention than I would have expected.

If one continues to examine the book with comprehensive coverage in mind, some regrettable general lacunae are to be found. Here I would pick out particularly the topic of behavioural ecology. It is a pity that this aspect of the biology of mammals, which throws such considerable light on their place in the ecosystem, is treated so sparsely. Similarly it is a matter for regret that food habits and feeding ecology are only briefly mentioned.

Perhaps it is too much to expect comprehensiveness in a book of this size, and it should simply be seen as a collection of more or less separate essays, reflecting the views of the authors about certain undoubtedly important areas of knowledge. As such the book is valuable, and can be read with profit by any serious ecologist, and by many others (doctors, veterinarians, pest controllers) whose interest in mammal ecology is more marginal. Professor George Varley once remarked to me that it was time the mammal ecologists got their subject to the same level as the entomologists. Perhaps we still have some way to go, but this book is proof that tremendous strides have been made towards this desirable goal. ☐

Ian Linn is Lecturer in the Department of Biological Sciences at the University of Exeter, UK.

Realm of pericyclic reactions

C. W. Bird

Organic Reactions and Orbital Symmetry. By T.L. Gilchrist and R.C. Storr. Second edition. Pp.311. (Cambridge University Press: Cambridge, 1979.) Hardback £25; paperback £8.50.

THE application of the concept of conservation of orbital symmetry in concerted reactions has had a profound effect upon the development of organic chemistry since its independent enunciation in 1965 by the late R. B. Woodward and R. Hoffmann, and H. C. Longuett-Higgins and E. W. Abrahamson. Not only did the concept facilitate the rationalisation of much knowledge, but more importantly it proved to have considerable predictive capability. The first edition of this book in 1972 provided a timely exposition of the rapidly expanding area, following hard upon the heels of the proselytising 'little blue book' of Woodward and Hoffmann with its peremptory claim "Violations. There are none!".

The reader of this most welcome second edition will search in vain for the dénouement usually visited upon such seeming arrogance by Murphy's Law. He will, however, find a lucid account of the theoretical origins and multifarious applications of this concept. A resumé of the chapter headings provides a guide to the topics covered: classification and investigation of reaction mechanisms (20 pages); theory of concerted reactions (23); electrocyclic reactions (26); cycloadditions: introduction (36); cycloadditions and eliminations involving six electrons (57); other cycloadditions (69); and sigmatropic rearrangements and related reactions (63). While providing in a largely non-mathematical form accounts of the various alternative approaches to the underlying theory, stress is now placed upon the particular merits of the frontier molecular orbital approach. However, as might be expected of practising experimental chemists, the authors have emphasised throughout the synthetic applications of these pericyclic reactions. They have also succeeded admirably in their intention of providing a perceptive up-to-date introduction to the subject rather than an exhaustive survey, although extensive references to other books, review articles and original papers are provided for those requiring further information.

Like its predecessor this book provides an excellent introduction to the realm of pericyclic reactions, and can be unhesitatingly recommended to both neophyte and pedagogue. □

C. W. Bird is Reader in the Department of Chemistry at Queen Elizabeth College, University of London, U.K.

Laser speckle

T.S. McKechnie

Laser Speckle and Applications in Optics. By M. Françon. Pp.161. (Academic: New York, London and San Francisco, 1979.) $16.

THIS book gives a concise, well ordered account of the origin and nature of speckle and of how it can be applied usefully. There are many illustrations in the book (158 in total), and with an absence of all but the most trivial mathematics, it makes pleasant and comfortable reading. The book has ten chapters, each broken into about six sections.

Chapter 1 begins by considering the image of a point source, and from this very humble starting point it progresses to deduce the image of many point sources, that is, a speckle pattern. Chapters 2 to 5 consider the effects of changing some of the variables which govern the speckle patterns. In addition to many more, consideration is given to such things as changing the plane of observation of the speckle pattern and changing the orientation and wavelength of the illumination. To one who might regard speckle patterns as being random and ungoverened by sensible laws, the results outlined in these chapters will come as a pleasant surprise. There are many ways in which speckle patterns behave simply and predictably, and the author has brought this out very clearly. The material comprising these chapters forms a basis for the applications which are dealt with in the remaining chapters.

Image processing is considered in chapter 6 and, along with several others, techniques are described for extracting the difference between two images, as are techniques for coding and decoding images. Chapter 7 is concerned with the study of displacement and deformation using speckle patterns. Chapter 8 concerns speckle in astronomy and the elegant method of Labeyrie for gaining diffraction limited performance from the largest telescopes. Chapter 9 deals with the measurement of surface roughness and Chapter 10 deals with various other applications of speckle patterns which do not fall within the previous categories.

The book presents a simple concise account of the subject. Researchers will find it very useful as a book for first reference; and, for those who wish to go deeper into the subject, an extensive list of references is given. □

T. S. McKechnie is in the Department of Mechanical Engineering at Loughborough University, Loughborough, UK.

Two International Journals

IMAGERY and REMOTE SENSING including CLOSE-RANGE PHOTOGRAMMETRY/ IMAGERY

Here is a highly topical and practical journal with a difference. The new-style approach will enable subscribers to enjoy, in easily understood magazine-type text, reading about all the international developments in these highly specialised technologies, the people behind them, and all those specialists who apply their skills to interpret the imagery produced from the complex instrumentation systems. In addition more conventional academic-type research articles and reviews in both theoretical and practical aspects will be included, with particular emphasis on interpretation.

Beside the conventional fields to be covered, such as geology, hydrology, forestry, etc. this journal will include natural disaster investigational reports, image transmissions from extra-terrestrial probes, satellite/avionic tracking and optical imaging systems, thermal imagery, military applications in peace and war, and aerial/underwater archeology.

Initially 5 issues a year; A4 format. Subscription: £43 one yer, 20% discount 2 years, 30% discount 3 years.

IMAGERY and REMOTE SENSING ABSTRACTS

This will cover the same fields as the main journal (but excluding the Close-Range Imagery Supplement) with an initial output of some 5,000 abstracts in over 1,000 pages.

5 issues. Subscription: £97 one year, 20% discount 2 years, 30% discount 3 years.

W.W. NORTON

Anatomy of an Illness

As Perceived by the Patient

Reflections on healing and regeneration

Norman Cousins

Introduction by Rene Dubos

Anatomy of an Illness is the true story of a recovery from a crippling and supposedly irreversible disease. It is the story of a partnership between a physician and patient in beating the odds. The doctor's genius lay in engaging to the fullest the patient's own capabilities for overcoming illness. This concept of patient responsibility for his or her own well-being is beautifully defined and illustrated in this book.

Geophysics of Mars

Garry E. Hunt

Geophysics of Mars. Developments in Solar System and Space Science, Vol.4. By R. A. Wells. Pp.678. (Elsevier Scientific: Amsterdam, Oxford and New York, 1979.) $87.75; Dfl. 180.

FOR centuries, the planet Mars has been the centre of intrigue for Mankind. Across the cold icy darkness of space, there has always been speculation that life could have developed on our planetary neighbour. In recent years, detailed observations from spacecraft have added to our measurements of the Martian environment by Earth-based telescopes, so that we are now building a fairly comprehensive picture of the planet now, and some interesting indications of its past. In this monograph, Dr Wells has produced a huge text which tries to put into perspective our current understanding of the geophysics of Mars. I believe he has largely succeeded in a well written and carefully illustrated text.

Naturally, the structure of the text and its content must have some personal biases, but fortunately all of the eight chapters have a wealth of references to supplement the material, so that the reader will not feel that his understanding of Mars is too strongly influenced by the author's own views. We are led into the discussions of Mars through the physical interaction of the atmosphere and surface. The importance of the Martian atmosphere in shaping some of the surface features and the minor constituents in providing information on the past history of the planet are reviewed. The chapter continues by introducing the basic spectroscopic matters related to the detection of atmospheric constituents such as CO_2, CO, O_3 and H_2O, their variability, and the basic techniques of determining the surface pressure and aerosol content of the atmosphere. Mars does possess a very exciting meteorology and I personally think it is unfortunate that this characteristic has not been highlighted more. There is some discussion of the cloud systems seen on the planet, but those seen by Viking in the Tharsis area, such as bore wave clouds, are unfortunately incomplete. The discussion of the dust storm generation misses out the fundamental observations by the Viking imaging and infrared instruments which have clearly shown that separate mechanisms are responsible for the preperihelion and perihelion storms.

Two of the most controversial aspects of Mars are concerned with the obscuration of the dark surface markings at short wavelengths and the progressive, seasonal, cyclic increase in their darkness at long wavelengths. These aspects are more familiarly known as the blue haze and the seasonal wave of darkening, respectively. A complete chapter is devoted to these matters. The discussions are very thorough. The reader will also be introduced to some of the problems and applications of Mie scattering theory in a simple and effective way which is always useful.

The next three chapters deal with different aspects of the basic surface properties of the planet. The geological aspects of Mars are built up from our early telescopic observations and subsequently improved with the spacecraft data through the 1960s until the present Viking data is available. A brief discussion is given of the problem of estimating the age of a surface by crater counting, but I am not sure whether the reader will necessarily know which set of results he should believe at this stage. The remaining two chapters of this sequence cover the Martian topography and the linear features. It may be sad for some readers that Lowell's infamous canals do not relate to any of the Martian features. However, this situation is in itself a valuable calibration, and a direct indication of the care we must take in interpreting visual observations.

Two further chapters cover the internal structure of the planet, mantle convection and the Martian moons, Phobos and Deimos. The monograph concludes with a detailed discussion of the first few months of the Viking view of Mars. As a result, a great deal of the seasonal aspects, and all the annual variations of the atmosphere, are not included.

This book has been written with great care, and there is every indication that the author has devoted himself to this task of placing on record the geophysics of Mars. I certainly believe that it is a valuable addition to the discussion of the Martian environment, and is well supplemented by a large number of high quality diagrams and photographs. But how many people, or indeed libraries, can really afford £41? I wish publishers would try to be a little more realistic in their prices; then good books, such as this one, would reach a much bigger audience. □

Garry E. Hunt is Head of the Laboratory for Planetary Atmospheres, Department of Physics and Astronomy, University College, London, UK.

Electron microscopical techniques

S.J. Kirchanski

Electron Microscopy and Cytochemistry of Plant Cells. By J.L. Hall. Pp.444. (Elsevier/North Holland: Amsterdam and New York, 1979.) $46.25; Dfl.95.

THIS book is indeed a pleasant surprise; all too often edited volumes are very uneven in quality and contain unfocused or inappropriate chapters. On the contrary, in this work all the chapters are of good quality and contribute an overall unified aspect to the volume. There are seven chapters which cover preparation of thin sections, enzyme cytochemistry, labelled antibodies and lectins, ion localization, autoradiography, freeze fracture and scanning electron microscopy.

Each chapter begins with a useful outline of its contents. The reader is introduced to the techniques covered in the particular chapter, and in some cases a brief historical review of the subject is undertaken. This is followed by detailed descriptions of the various technical steps along with informative discussions of alternate methods in most cases. Each chapter is thoroughly illustrated and has a good, current bibliography. The overall quality of printing is high and the micrographs are well reproduced. The chapters on thin sections, cytochemistry and lectins each end with appendices of methods and recipes which will doubtless prove extremely popular with most researchers.

Of course, given the space restraints of the volume, it is not possible for each chapter to be absolutely complete. Different workers will undoubtedly notice different omissions. In the chapter on thin sectioning I was pleased by the detailed treatment of staining (although I believe that Reynolds should have been credited with the lead citrate procedure that was presented), but I felt that insufficient discussion was given to the value of low viscosity resins for embedding plant materials. In the same way, though I felt that the historical treatment of freeze fracture and the descriptions of standard freeze-fracture methods were masterful, I think that insufficient coverage was given to low-temperature, rapid freezing (Heuser-liquid helium methods) and the revolution that rapid freezing is currently causing in freeze fracture. Nevertheless, this is an excellent volume and should be available in all biological research libraries. Although the material is aimed towards plant biologists, it is of use and value to all biological electron microscopists. In spite of the volume's rather high price, I predict that many researchers will purchase it as a personal reference book. □

S.J. Kirchanski is a Postdoctoral Research Fellow and Lecturer at Harvard University Biological Laboratories, Cambridge, Massachusetts.

OBITUARY

L. P. Garrod

LAWRENCE PAUL GARROD, emeritus professor of bacteriology in the University of London died on 11 September 1979, aged 84. He was born on 7 September 1895. After school at Sidcot, Garrod's medical training at King's College, Cambridge and St. Bartholomew's Hospital was interrupted by service in 1917 and 1918 as a Surgeon Sub-Lieutenant, RNVR. At Bart's, his career as a student was outstanding and he won the Senior Scholarship in Medicine. In due course, after qualification, he became Chief Assistant to Dr Morley Fletcher and at that stage he seemed bound for the staff of the hospital as a consultant physician. But in 1925 he turned to pathology and then bacteriology, being appointed Professor of Bacteriology in the University of London in 1936, a post which he held with that of Bacteriologist to the hospital, until his retirement in 1961.

At Bart's he was a familiar and much respected figure. To the thousands of Bart's doctors who were taught by him during his time, he will probably best be remembered for his lectures and the associated practical classes at which he was a meticulous attender. A very clear logical speaker, his lectures were illustrated by a series of anecdotes and comments that held the attention of his students. To the hospital staff, his wide clinical and laboratory experience was always available. His opinion was always worth having and was much sought.

To a much larger audience, Garrod was known for his research and for his writing. Before the last war he became interested in disinfection and sterilisation, a subject that attracts the interest of few doctors, and he rapidly became one of the leading authorities in the country, with his name attached to one of the standard tests for disinfectants. This early experience stood him in good stead with the discovery of sulphonamides and then antibiotics, and a flow of papers began from his laboratory, many with his assistant, Miss Pamela Waterworth, dealing with chemotherapy in general and the properties and uses of each new antibiotic as it emerged. He played an important part in the Medical Research Council's trial of the penicillin treatment of subacute bacterial endocarditis, that was to set the pattern for many subsequent clinical trials.

As a writer, Garrod's contributions, both recognized and anonymous, were immense. He edited the *British Journal of Experimental Pathology* for many years and his close association with the *British Medical Journal* ran from 1931 until he died; he served on various committees and was at one time Chairman of the BMJ Journal Committee. When he retired from Bart's, the then Editor of the British Medical Journal, writing in the Hospital Journal, said that "it is difficult for me to say just how much we on the staff of the BMJ — and its readers — owe to Garrod. He has written book reviews, leading articles, annotations, answers to questions, all with effortless ease, precision of style, accuracy of fact, and a certain marked honesty that has been vastly refreshing."

Apart from his other writing, he was co-author of three books. First, before the war, *Recent Advances in Pathology* with Geoffrey Hadfield and then after the war, *Antibiotic and Chemotherapy,* first with Mary Barber and later with Francis O'Grady, and *Hospital Infection* with R.E.O. Williams and others. Retirement did not slow his pen, and he continued his work for the BMJ as well as answering the many invitations to speak that he received from this country, Europe and the United States.

Professional recognition came his way by honours and appointments. His views were sought as a committee member by the Department of Health, the Medical Research Council and World Health Organization. He examined for the Universities of London, Oxford and Cambridge. He was president of his section of the Royal Society of Medicine, Vice-President of the British Medical Association, President of the Institute of Medical Laboratory Technology, Consultant in Antibiotics to the Army, and on retirement, Honorary Consultant in Chemotherapy to the Royal Postgraduate Medical School. The University of Louvain conferred the title of Honorary Alumnus on him, Glasgow awarded him an Honorary Doctorate of Law and the Royal College of Pathologists elected him an Honorary Fellow.

R.A. Shooter

John Raymont

THE sudden death of Professor J.E.G. Raymont on 30 August 1979, at the age of 64, has deprived the world's community of marine scientists of a respected member and the field of zooplankton of one of its most distinguished students.

His interest in zooplankton began at University College, Exeter where he took first class honours in zoology, and was soon reinforced during 1937-38 when he held a Henry Fellowship at Harvard and spent the summer of 1937 at Woods Hole. After a brief return to Exeter as assistant lecturer he was appointed Lecturer in Zoology in Edinburgh in 1939. There, in conjunction with Sheina Marshall, F. Gross and A.P. Orr, a study was commenced on the effects on plankton and fish productivity of fertilising sea lochs, which was a precursor to marine fish farming in enclosed waters. During this period he met and married Brigit Sloan, who remained his constant companion at home and colleague at work in an enviably happy marriage.

In 1946 John Raymont moved back to the south to take up the Chair of Zoology at Southampton at the early age of 31. A generous grant from the Goldsmiths' Company enabled the purchase of the department's first boat, *Aurelia,* and his attention, after a brief period of working with other organisms, turned back to plankton. This was an era of public and scientific interest in the possibility of utilising plankton directly or indirectly as food organisms and he initiated long-term studies on the composition and physiology of zooplankton species. One of the researchers attracted by his studies in this field was a young Indian biologist, S. Krishnaswamy, who subsequently collaborated with John Raymont on several occasions. Partly through this connection and partly from international prestige gained as a result of his definitive work *Plankton and Productivity in the Oceans* (1963), John Raymont was invited under the auspices of the Indian U.G.C. and the British Council to advise on the establishment of the Centre of Advanced Marine Studies at Porto Novo. Thus began a long association with the training of oceanographers in many lands which culminated in membership of such bodies as the I.O.C. (Training, Education and Mutual Assistance), S.C.O.R., Nuffield Tropical Marine Biology Fellowship Panel and Chairmanship of the UNESCO Advisory Panel on International Marine Biology Centres.

At Southampton his academic career was crowned by appointments as Dean of the Faculty of Science 1961-1963 and Deputy Vice Chancellor 1966-68. His real ambitions lay, however, in a somewhat different direction and these were fulfilled in 1964 with the foundation of a department devoted to the study of marine science in all its aspects. Under his skilful guidance the staff of this multidisciplinary department were welded into a coherent and integrated unit in spite of their disparate research interests. The department quickly gained the international reputation which will live on as a monument to John Raymont's skills as a quiet unifier.

His international commitments, research culminating in some 60 papers, and administration came nowhere near exhausting his energies and over the years he was *inter alia* an adviser to the C.E.G.B. on matters relating to warmed water release, a member of the British National Committee for Oceanic Research and the Royal Society Pollution Study Group, member of the Councils of the Fresh Water Biological Association, Marine Biological Association and National Institute of Oceanography. As Chairman of the

Planning and Development Committee of the Wessex Regional Hospital Board and later as Vice Chairman of the Hampshire Area Health Authority, he was deeply involved in the expansion of hospital services in the area.

He was honoured by the award of the OBE in 1978 and earlier by election to a Fellowship of the Indian Academy of Sciences.

Marine scientists the world over will grieve the loss of a man who by quiet example was able to foster participation between research workers at every level, of different interests and from many nations.

A.P.M. Lockwood

Jack Tizard

PROFESSOR JACK TIZARD died in London aged sixty, on 2 August 1979, as a result of cancer found to be inoperable eight months earlier. So passed one of the foremost post-war research workers in mental retardation and child development.

Born a New Zealander, Jack graduated there and after overseas Army services undertook a postgraduate degree at Oxford where he met his wife. In 1948 he joined the Medical Research Council's Social Psychiatry Research Unit at the Institute of Psychiatry in London, and with his colleague Neil O'Connor was directed by Professor Aubrey Lewis into the neglected field of mental deficiency. He was appalled by the situation he found in hospitals for the mentally defective which in those days were used as places where socially disadvantaged young people could be put away. As a fearless man he said so, among other things challenging the medical model which was enshrined in the 1913 Mental Deficiency Act. Tizard and O'Connor set about showing that industrial habilitation leading to fairly rapid discharge from care was a viable possibility. Their pioneering studies on the mildly retarded were brought together in 1956 in an important book *The Social Problem of Mental Deficiency*.

However, there was more to do. There remained the moderately and severely retarded who were on the whole considered unemployable in even the simplest capacity. In a series of innovatory experiments it was shown that young adults with intelligence quotients in the thirties and forties could in certain circumstances learn, respond to incentives, retain their learning and transfer it to rather different situations. Others built upon and extended this work which cast new light on our potential for helping the more severely disabled, and their own potential for change.

Jack himself was ready to move on, and with the help of Dr Leslie Hilliard transferred a number of mentally handicapped children out of the Fountain Hospital and into a country house which resembled a boarding school. In 1961 he published *The Mentally Handicapped and Their Families* (with J.C. Grad) and in 1964 *Community Services for the Mentally Handicapped*. His belief that the quality of the social structure and organization of any community is a major determinant of development and behaviour of its members led him into the field of social policy.

In 1964 Jack was appointed to the first Chair in Child Development at the University of London; his outstanding contribution to the study of mental subnormality was acknowledged in 1968 when, jointly with Neil O'Connor, he received the Kennedy International Scientific Award, to be followed in 1973 by the annual research award of the American Association on Mental Deficiency. In the early nineteen-seventies, as Research Professor, he founded The Thomas Coram Research Unit, a unique multi-disciplinary establishment in which medical and a variety of social scientists collaborated in policy-oriented research projects. His erudition, high intelligence and unusually attractive personality ensured that he became much in demand for committee work. An excellent and incisive chairman, he was invited to act in several different capacities for a large number of organizations including the Social Science Research Council, the Department of Health and Social Security, the Association for Child Psychology and Psychiatry, the WHO Expert Committee on Mental Health, and for the British Psychological Society as president. He was appointed CBE in 1973.

Despite his generous contribution to committees, his research continued to flourish, and a steady flow of books and articles appeared over the years on a wide variety of topics relating to children. Jack Tizard was an example of that unusually effective individual, a radical thinker accepted by the Establishment.

In the final eight months, much of it in pain, Jack's bearing befitted his life. Fortitude, equanimity and hard work were his daily purposes; his courage was well matched by that of Barbara, his wife. Their long, happy marriage must have given both a background of security, and contributed in no small measure to the success each enjoyed.

To say of a man that "we shall not see his like again" is often a sentimental exaggeration; in the case of Jack Tizard, this is not the case. Those hundreds of us who knew him personally must feel a deep sense of loss at his passing.

Ann Clarke and Alan Clarke

Marcel Florkin

BORN in Liège, Belgium in the first year of the new century (15 August 1900), Marcel Florkin died in Liège on 3 May 1979. His early education and his medical degree were also at Liège, but thereafter he gained international recognition through his contributions in the areas of invertebrate physiology, comparative biochemistry and physiology, biochemical evolution, and origin of life, as well as through numerous roles in the development of international aspects of biochemistry.

Florkin's interest in physiology and biochemistry were increased by study in the laboratories of such eminent scientists as Joseph Barcroft, Richard Kuhn, Heinrich Wieland, and Edwin Cohn, following which he spent 36 years in teaching and research at the University of Liège, interrupted by visiting professorships at Duke University and the Universities of Washington and Oregon.

Perhaps the most compelling urge of his life in science was to extend his interests and contributions beyond ordinary limits, into broadly related areas of history, comparative aspects of physiology and biochemistry, evolution, and the nature of men who have contributed uniquely to the field of biological science. In addition to his numerous individual contributions, he undertook prodigious tasks of assembling as senior editor the world's contributions in multi-volume collections in various fields. Witness the ten volumes of *Chemical Zoology*, the seven volumes of *Comparative Biochemistry* (Florkin and Mason), and the 34 volumes of *Comprehensive Biochemistry* (Florkin and Stotz). The last five volumes of the latter series were devoted to the *History of Biochemistry*, his own contribution, and constituting written testimony to his critical and intimate knowledge of the great events in biochemistry. Included in his *History* is a remarkable collection of photographs of pioneers in biochemistry, itself a notable tribute to his perseverance and human touch.

Florkin contributed greatly to the role of biochemistry at the international level. In 1952 he became chairman of the International Committee of Biochemistry, and in 1955 was named the first President of the newly formed International Union of Biochemistry, following which he was instrumental in gaining admission of the newly formed Union into the International Council of Scientific Unions. As first Treasurer of the Union, the writer can attest to the diplomatic skills and warm spirit of negotiation displayed by Professor Florkin.

Marcel Florkin gained many honors and awards in his active life, including honorary membership in the Royal Institution of Great Britain and honorary fellowship in the Royal Society of Edinburgh. Yet in his busy life he maintained an active interest in the arts, and seldom missed an opportunity in his travels to find a moment for a visit to the local art museums to view their recent acquisitions. It is not surprising that he was devoted to family and close friends, who, along with many scientific colleagues, will miss his great warmth and human spirit.

21 February 1980

The Brandt report: better luck this time?

BLUEPRINTS for global survival have become an increasingly common fixture in popular debate over the past few years. Frequently presented with almost millenarian zeal, their appeal reflects an awareness that the growing interdependence of national economies has also nurtured potentially self-destructive tendencies of global proportions. The report* of the commission,headed by ex-West German prime minister Willy Brandt, suffers, like many of its predecessors, from a heavy overdose of idealism. But it deserves to be taken seriously, because it appears at a time when the stability of East-West and North-South relations is more fragile than for the past twenty years.

In one sense the Brandt Commission — officially known as the Commission in International Development Issues — picks up where the Pearson Commission left off ten years ago. At that time, the main question was the appropriate level of development "aid" which the rich countries should provide to the poor; Pearson's answer was to set a target (which few countries have lived up to) of 0.7% of gross national product. Since then attention has shifted from the level of aid contributions to the conditions under which development can take place. And one way to read the Brandt Commission's report is as a reply to recent vocal demands for a "new international economic order".

The commission's message is that the development of a strong global economy will be of mutual benefit to rich and poor countries alike; but that this will not be achieved merely through the unfettered workings of the global market-place. What is recommended is almost a formula for an international welfare state. Political institutions, the commission argues, need to be developed which will protect the weakest actors on the international scene; bring order to the financial chaos which would result if market-forces were left unchecked; and seek redistribution of global wealth through international taxation.

As a prelude to this strategy, the report repeats a by-now familiar litany of the sad state of the world we live in. Furthermore, many of the specific proposals also carry a familiar ring. Some have already been heard from numerous multilateral aid bodies. Others are more often proposed by the developing countries themselves, and their espousal by a commission calls both for a massive transfer of resources from the developed to the developing nations, and for a strict code of conduct to regulate the activities of multinational corporations. At present both are being resisted, the former most recently at the Delhi meeting of the United Nations Industrial Development Organisation (UNIDO), which ended in stalemate earlier this month. There are other, less familiar, suggestions. For example, the commission devotes a chapter of its report on energy. It recommends that there should be a global energy research centre, established under UN auspices.

But it is in the field of economic reform that the commission makes some of its most far-reaching, controversial, proposals. Here the commission is calling for no less than the restructuring of international financing mechanisms, particularly to cope with the cash surpluses arising from the oil revenues of the OPEC countries. One of the most significant aspects of the redevelopment scene over the past decade, it points out, has been a shift from government-financed aid to loans from private banking and commercial institutions, many of which have used such loans as a way of recycling OPEC deposits.

The commission argues that this massive recycling has created instabilities in the system which the private sector may prove inadequate to control; and that the massive debt burden already carried by many Third World countries will inevitably dominate development efforts for many years to come. Furthermore aid offered on commercial loan terms will tend to encourage relatively short-term development needs. But the commission is also critical of the stringent conditions laid down by the International Monetary Fund for loan assistance, arguing that these have often "tended to impose unnecessary and unacceptable political burdens on the poorest", and have led countries to prefer the private international banks.

The solution suggested by the Brandt Commission is to institutionalise ways of liberalising the international financing system. With respect to the IMF, for example, it suggests that the fund should "avoid inappropriate or excessive regulation" of the economies of the developing countries, and not impose "highly deflationary measures as standard adjustment policies". As far as the World Bank is concerned, the commission suggests, among other things, a shift to greater emphasis on programme loans, which would give a country flexibility in the methods it adopts to achieve a certain broad objective; it also suggests decentralising the bank's activities from Washington and giving a greater role in decision-making to representatives of the Third World.

Talking in realistic terms, any moves which would circumvent the role of existing financial institutions are certain to meet considerable opposition. Equally controversial is the suggestion for an international taxation system, all countries being assessed for their ability to pay into a general fund which would be made available for development purposes. The political appeal of such a system, possibly taking the form of a tax on international trade, is obviously limited; yet in his introduction to the report, Willy Brandt states that "by the end of the century the world will probably not be able to function without some practicable form of international taxation."

Those who followed last year's UNCSTD debate closely will not have missed the irony. For one of the major stumbling blocks in Vienna was the refusal of the developed countries to agree to the creation of a new fund, proposed by the developing countries to be based on contributions automatically assessed as a percentage of the trade in manufactured goods between rich and poor countries. It was merely agreed to establish an interim fund, based on voluntary contributions.

Indeed the commission's sketchy reference to the UNCSTD conference, grasping the inadequacy of its conclusions but providing little insight into why no more was achieved, merely illustrates the report's major weakness. For it is written more as a political manifesto than as a realistic framework for planning; but one that, given the growing attractions of protectionism and monetarist policies, lacks wide appeal at present. Furthermore the message that it is in the self-interest of the rich to promote the development of the poor inevitably invites the scepticism of those who would claim it as an expression of neo-imperialism.

But in one instance at least, the commission is correct. Suggesting that the industrialised countries restimulate their efforts to meet the aid targets to which many are already committed — and indeed to aim for 1% of GNP by the year 2000 — it adds that "what the neglect of foreign aid expresses is ultimately the lack of political priority attached to it." Next month in New York will see the pledging conference for the interim fund recommended by UNCSTD to finance new scientific and technological endeavours in developing countries, administered by the United Nations Development Programme. The event will indicate how much the main recommendations of the Brandt Commission have been taken to heart. Current indications are that total contributions will be less than initially hoped for although some countries — Britain excluded — will feel it appropriate to make reality of the Brandt Commission's analysis; and the acceptability of its message. □

High energy physics

Money may determine West Germany's view

IN the battle — imagined or otherwise — between the Hamburg laboratory DESY and the European subnuclear physics centre CERN near Geneva, Germany will give CERN priority, unless outside factors intervene. So Dr Günther Lehr, director for international cooperation of the German federal minsitry for research and technology, told *Nature* last week.

The pace of diplomacy over the issue between Italy and Germany is increasing. Italy was the first to raise doubts about German intentions. In the past few days the Italian minister of science, Vito Scalia, met Lehr with the chairman of the European Committee for Future Accelerators, Professor Marcel Vivargent, in Zurich — construed as neutral territory. And Professor Herwig Schopper, director of DESY and holder of all but Italy's vote to be CERN's next director-general, visited Scalia in Rome to clarify his position.

However, according to a Rome diplomat "it is still too early to say" if all the problems are solved. "Time has been useful" he said. "It has removed the cloud to a certain extent, there has been a clarification of problems."

Italy, which since the closure for high energy physics of its ADONE electron ring at Frascati near Rome has relied heavily on the CERN facilities at Geneva, fears competition between DESY's plans for an electron-proton ring, HERA, and CERN's plans for a large electron-positron ring LEP. The first stage of HERA, which would probably operate some years before LEP, would also be an electron-positron ring though at a nominal energy of 35 GeV on 35 GeV (see *Nature* 31 January page 420), below reach of the intermediate vector boson. Italy has perceived Schopper's potential appointment to the CERN director-generalship as a "Trojan horse" which would lead to the running down of CERN and the aggrandisement of the DESY laboratory in Hamburg.

But Lehr dismisses these fears. "DESY has risen in the last few years from a purely national laboratory to one of international importance" he said last week. "At first this caused surprise, and now there is overreaction."

Lehr is now convening a small group of scientific advisors to make recommendations, sometime this year, on spending in Germany on ten 'big projects', including LEP and HERA. Others include a new neturon source, equivalent to the UK Rutherford Laboratory's spallation neutron source now under construction, a European synchrotron radiation source as proposed by the European Science Foundation, improvement of the heavy ion accelerator at Darmstadt, and a deep drilling project to reach the Mohorovicic discontinuity, the 'Mohole' project dropped by the US some years ago.

Since Germany contributes 25% of CERN costs (the maximum allowed), the costs to it of LEP and HERA are roughly equal. But, said Lehr, "I would assure Scalia in Zurich that the LEP and HERA decisions would be independent. I cannot see us doing HERA instead of LEP. I rule out doing neither, but I see no basis for choosing HERA in favour of LEP, unless it is for reasons outside our control."

Such reasons might be objections to LEP from other member states of CERN. The Scandinavians particularly are thought to be cool to LEP (after all Hamburg is closer than Geneva) and the UK is likely to be in favour only if LEP is built slowly, to reduce annual costs.

However, cost is also a prime consideration in Germany, and Lehr does not know how much money will be available to him. Discussions are presently taking place on the science ministry budget for 1981, and it appears that there will be only "a relatively small increase" constrained by the international economic and political situation. There will not be enough money for all the big projects, but may be enough for more than one — perhaps 50 million DM per year.

"In these circumstances", says Lehr, "I cannot forecast my minister's reaction" to a proposal to go ahead with LEP and HERA together. This uncertainty leads directly to Italy's doubts. If Germany decided to go ahead with HERA before there is a decision on LEP (which will not come before the CERN council meeting of June 1981 at the earliest) would Germany be inclined to temper its enthusiasm for LEP?

Lehr regretted the Italian position on Germany and LEP "but in some respects I understand them, because DESY has been successful. CERN — I choose my words carefully — has been better at building superb accelerators than at discovering spectacular physics."

Schopper: CERN's next director-general?

Why should this be so? Because, suggested Lehr, the director general of such international bodies tries always to be on the safe side, to build an accelerator which runs on the touch of a button. "We should consider this matter" said Lehr, who is also vice-president of CERN Council, "and perhaps change this policy. We could build this smaller, cheaper, and take risks . . . . It will not be possible to build larger and larger particle accelerators: governments and other scientists won't accept it." Schopper, Lehr believes, would be a director general who would take imaginative risk, as he has done with DESY.

The Italian science ministry, however, told *Nature* last week that there could be no decision on the director generalship, Rome's main political weapon, before the June meeting of CERN Council, and that the time before then should be used to clarify the issues further. Lehr, on the other hand, insists that Schopper's early appointment as director-designate — the post is effective from January 1981 — would help to clear the ground for LEP. Strictly, a two-thirds majority is all that is required for a decision, but it is felt that unanimity is necessary on this appointment.

Scalia and Lehr appear to agree on one thing: the need for speed with LEP, if it is built. Lehr would like it built in five years rather than the seven which is current CERN thinking. This can be done within a 'constant' CERN budget of 620 million SwFr a year, says Lehr, if a minimum one-sixth version of LEP (with a maximum luminosity at 49 GeV) is adopted. Italy is in agreement with this. It would entail the same tunnel, but having fewer accelerating cavities so that the machine just reaches the mass of the intermediate vector boson, the Z_0.

Lehr sees US competition for the Z_0 as less of a threat than some: "John Deutsch has told me that his department of energy will spend some $300 million on Brookhaven National Laboratory, Fermilab, and the energy doubler, and Richter's Z_0 factory, so you can expect delays for lack of funds."

Rome does not regret the stand it has taken. A diplomat in the science ministry told *Nature* last week "our pressure has produced an increased awareness of the need for speed. The matter has been brought into the limelight." The diplomat "found room for agreement" in the language now used by the German delegates to the CERN Council. "We believe Germany is a very strong member of CERN, and wish it to ramain so."

United States

USDA to study potential anti-social effects of sponsored research

FOLLOWING the US Department of Agriculture's decision to stop funding research that would throw farm workers out of their jobs (*Nature* 3 January 1980 page 5), Agriculture Secretary, Mr Bob Bergland, has now announced a study into the possible anti-social effects of all federally-funded research.

The task force that will undertake the study will concentrate on the $1 million which the Department spends annually on research at universities and land grant colleges into the mechnisation of agricultural production. This has been subject to criticism that led to the decision to halt new funds for such research.

In a speech to the staff at the Department's Science and Education Administration at Reston, Virginia, Mr Bergland repeated that he would no longer support research whose benefits would be restricted to a particular locality or social group, or which posed a threat to the natural environment or social community.

"In the specific case of mechanisation research, this means that we will not put federal money into research where — all other factors being equal or neutral — the major effect of that research will be replacing an adequate and willing workforce with machines", Mr Bergland said.

However he added that the economic incentives of the market-place should be powerful enough to enable this type of research to be funded by private industry, either by itself or with the help of state funds.

Mr Bergland said that this policy was consistent with the department's responsibilities to meet national needs, rather than those of a particular group. The government should not finance research whose beneficiaries could, in an extreme case, use it "to gain control of the farm-to-market structure, monopolise the sources of finance at every step, and increase their profits by selling what may well be an inferior product at a price that is insulated from competition".

He pointed out that until recently, agricultural research had been evaluated almost exclusively in terms of what the research promised in the way of volume productivity gains; too often potentially significant negative economic and social effects were not factored into the evaluation.

"The result was a skewed cost-efficiency statistic and distorted perspective. If this is not remedied in the research evaluation process, it will surely handicap our ability to meet changing national priorities", Mr Berland said. This was the reason for establishing a task force to look for research projects involving "the dubious use of federal money." □

New group to study cryptography policy

WAYS of resolving conflicts between the academic freedom of researchers working on computer codes and the interests of national security are to be investigated by a group that has been established by the American Council of Education, under a grant of $32,000 from the National Science Foundation.

The chairman of the study group will be Dr Werner Baum, dean of the college of arts and sciences at Florida State University. Dr Baum was previously chancellor of the University of Wisconsin at Milwaukee, where in 1978 a computer scientist, Dr George Davida, had a patent application for a new computer code blocked by the Department of Commerce following objections from the National Security Agency.

Dr Baum told *Nature* recently that he hoped the study group would be able to recommend policies and procedures which would both protect the legitimate academic and property concerns of universities and research institutions on the one hand, and the concerns of the US government about security on the other.

He added that this might involve changes in the law. In the Davida case, for example, which was successfully challenged by the university, Dr Baum pointed out that the NSA had no due process requirement covering demands that an individual should not publish the results of his research for national security reasons. Current law, he said, which goes back to the post-war McCarthy period, may turn out to be non-constitutional.

The ACE working group was established after NSA director Admiral Bobby Inman last year suggested a dialogue with the scientific community on conflicts between academic freedom and security issues. The group will include representatives of professional societies such as the American Mathematical Society and the Computer Society of the Institute of Electrical and Electronic Engineers, as well as legal advisers. It is expected to produce a report within a year.

Last year Admiral Inman was quoted as supporting legislation which would control research and the subsequent publication of results of "a central core of critical cryptologic information . . . that is likely to have a discernable adverse impact on national security." □

Battelle paints healthy picture of US R&D

IN contrast to the frequent complaints still heard about the health of US research and development, a surprisingly lively picture of the current situation is presented in the latest annual analysis by the Columbus Laboratories of the Battelle Memorial Institute. Taking R&D expenditures across the board, Battelle estimates that these will grow by 19.7% in 1980, to a total of $61.8 billion. Within this total, industrial funding is expected to grow faster (20.9% increase) than federal funding (19% increase); but even given a predicted cost increase of 12%, this still implies a 7% real growth in expenditure, reaching a new peak in total real funding of R&D, the report says.

Despite the unfavourable economic climate, the Battelle report says that there are many intangibles, "particularly the reawakened feeling on the parts of many decision makers that R&D is essential to our long-term economic health — that favour greater-than-usual increase in support for research. The report says that its analysis indicates that the upward movement established over much of the past decade in R&D expenditures is likely to continue, with the 1980 figures leading to an average increase over the past seven years of 3.3% in real terms. It estimates that during the decade of the 1980s real R&D activity will increase at an average rate of approximately 3%.

The major sector to indicate increases in both funding and performance of R&D in 1980 is expected to be industry. In contrast, academic and other non-profit institutions are expected to register small decreases in the percentage of support and performance (3.5% and 15.1% respectively); but there will still be significant increases in the total activity of each (1.3% and 17.6% over the estimated 1979 figures).

The report says that therefore in spite of inflation and the desire of the Carter administration to balance the budget, there are signs of greater support for research. It points out in particular that industrial support is growing in fields affected by regulations and in those fields most directly influenced by the need for more energy-efficient products and processes. □

Finland

Public confidence in science is reviving

LAST week, Finland's Swedish-language technological society, the Tekniska Foerenigen I Finland (TFIF) held a panel discussion on the country's energy policy as part of the centenary celebrations of the society's foundation. According to Erik Moring, the president, of TFIF, the holding of this discussion, between five of the country's leading experts from both the government and private sectors, reflect the general theme of the year's celebrations — to show the country that scientists and technologists are not "some sort of monster."

The TFIF celebrations, with their strong emphasis on the best use of Finland's natural resources for the good of the country as a whole, coincide with Finland's current "environmental year", and a general swing of public opinion away from the strongly anti-science bias of the mid and late 1970s. On 8 February, the Social Democrats (the largest single party in the Finnish parliament) called for a major investment in science and the creation of 300 new research posts. A few weeks previously, Finland's highly charismatic president, Urho Kekkonen, called for a reassessment of R&D investment and the expansion of research facilities — the first time that the president called so directly for a boosting of science since 1964.

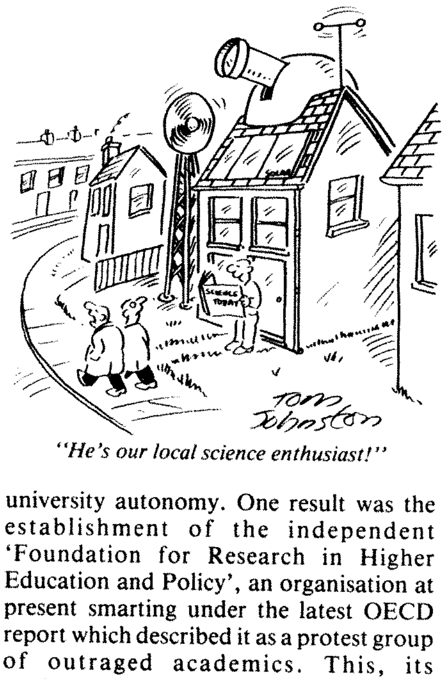
The result that previous appeal was a major reorganisation of research planning, leading in 1969, to the foundation of the Academy of Finland, which, in spite of its name, is essentially a system of research councils and of government science funding. When the Academy put forward its five proposals for increased government science funding as "areas of emphasis", these had a strong bias towards the social sciences: environment, work and working conditions, public health, basic necessities of the population and living conditions, and the implementation of democracy and equality. It was this last project that, in the opinion of many Finnish scholars, led to the breakdown of public confidence in science planning.

Undoubtedly the project did provide a vocal focus for grievances. According to its opponents, the results of the research were widely politicised by the left. A nationwide debate sprang up in the press causing considerable disillusion among the public. The academic professions, which increasingly tended to range themselves against the Academy, had, however, other complaints.

During the past 25 years, Finland's general policy of decentralisation has increased the number of the country's universities from two (Helsinki and Turku) to 18 (the last of which, the university of Lapland, was founded in 1979). Some of these are genuine new foundations, others are upgraded/former specialist or teacher-training colleges (e.g. the University of Jyvaeskylae). This proliferation was, to a large extent, necessary to prevent a permanent brain-drain to the south-west of the country.

However the expansion has left Finland, like many industrialised countries, with the problem of a very slow turnover of research staff in universities and few opportunities for new graduates who wish to stay within the Finnish academic structure.

An even more bitter cause for resentment, however, was the government regulation of the 1960s codifying and standardising the granting of academic degrees. This was, not surprisingly, seen as an encroachment on academic liberty, particularly since Finnish tradition followed the 19th century German ideal of university autonomy. One result was the establishment of the independent 'Foundation for Research in Higher Education and Policy', an organisation at present smarting under the latest OECD report which described it as a protest group of outraged academics. This, its spokesman, Dr Juha Vuorinen told *Nature*, is simply no longer true. "We are now cooperating much more (with the government) and the political issues are not so hot. What we are trying to do now is to influence the government to give more money to research. Research must be led by experts, not bureaucrats".



"He's our local science enthusiast!"

Certainly there are fields in which Finland is capable of taking a lead position. One is nitrogen fixation, traditional since the time of Professor Virtanen, who received the Nobel Prize in 1945. Another is the ultra-cold laboratory of the Helsinki University of Technology at Otaniemi. This laboratory was established by Professor Olli Lounasmaa in 1975 on the principal that low temperature physics is one of the frontier areas still within range of the Finnish budget. At present the laboratory holds the record of 50 nano-Kelvins (using a copper nuclear spin system). One byproduct of this work is the development of SQUIDS (superconducting quantum interference devices) to produce magnetic shielding. A magnetically shielded room is now under construction and an international seminar is to be held in May for potential users of what Professor Lounasmaa describes as "this rather expensive facility which will incidentally, be paralleled only by one under construction in Berlin."

Professor Lounasmaa's expertise in planning the laboratory has led to his being appointed head of a new working group to advise the government on the funding of basic research. Finland, he told *Nature*, has a very small bureaucracy. A scientist can therefore hope to obtain funds without too much red tape. Also, although the country has no long tradition in science, the general public, he says, has on the whole a high esteem for science. The disillusion of the last few years is not, he feels, significant in the long run.

Certainly one can find numerous examples in Finland of public confidence in science. Last autumn, the leading Finnish daily, *Helsingin Sanomat* celebrated its ninetieth anniversary with a special series of articles on science — which, in the opinion of Dr Elizabeth Helander, research director of the Academy of Finland, is the principal cause of the recent public change of heart. Some such gestures have involved considerable sums of money. In 1967, to mark the golden jubilee of the country's independence, the Bank of Finland set aside securities worth 300 million FM ($45 million) whose interest would be used to fund loans for R&D expenditure in the private sector. Some considerable financial daring is also involved in two new publishing projects. One, proposed by the Academy of Finland, is the publication of a new popular science journal which is expected to become financially independent within three years. The other is the publication of a five volume full colour encyclopaedia of Finnish wild life (the first ever such work), which is expected to sell 10,000 at 1600 FM ($220) the set. In a country of 4.5 million inhabitants and with virtually zero prospects of foreign sales, these figures assume that one household in ten throughout the nation contains at least one science enthusiast. **Vera Rich**

NEWS IN BRIEF

East-West "persecution" row at Hamburg Forum

USSR Academician Nickolai Blokhin has accused the US and UK of "trying to make a 180 degree turn" in discussing international scientific cooperation and "interfering in the internal affairs of the Soviet Union". Speaking at the Hamburg Scientific Forum this week, Blokhin, head of the Soviet delegation and president of the Academy of Medical Sciences of the USSR, accused them of "trying to be teachers of other countries when no-one asked them to". He was reacting to strong appeals from Lord Todd, head of the UK delegation and president of the Royal Society, and Dr Philip Handler, president of the National Academy of Sciences, on behalf of persecuted colleagues. Lord Todd cited the Soviet Union's behaviour in blocking invitations to scientists to go abroad, and the harsh treatment meted out to scientists "for comparatively minor disagreement with authority".

"Does the Soviet government yet realise", he said "the resentment this causes amongst young scientists? I call on our Soviet colleagues to impress on their government the urgent need for change".

Dr Handler stressed that many Soviet scientists were victimised owing to their wish to monitor the Helsinki Accords. There had been, he said "a spontaneous upswelling of reaction in the US." His delegation was present in Hamburg in spite of many high level scientists' appeal for a boycott.

Blokhin did not answer the charges specifically, but harangued the Forum with a long list of Soviet scientific achievements which he said the US and UK were trying to deny. It had been expected the Soviet delegation would be led not by him but Dzherman Gvishiani, deputy head of the State Committee for Science and Technology.

US probes illicit Soviet technology sales

The US Department of Commerce is currently investigating numerous cases of illicit sales of computer, laser and transistor technology to the Soviet Union, according to a document leaked to the *Los Angeles Times*. Although black market sales in high technology to the USSR and the socialist countries has existed for years, this is the first time the government has attempted to document its extent and significance. Citing such procedures as the creation of dummy firms, hand carried shipments without export licenses, and shipments made to illegal destinations, the document lists more than a dozen US companies who have engaged in this profitable but shady trade. Included are such small companies as I I Industries and Kasper Instruments in California's Silicon Valley, which pleaded guilty in 1975 to diverting $330,000 of semi-conductor equipment to the USSR by way of dummy firms in Canada, and Information Magnetics Corporation of Goleta, California, which shipped $880,000 worth of computer supplies to Bulgaria through a UK subsidiary. Larger firms named in the document include Texas Instruments of Stafford, Texas, Tektronix Incorporated of Beaverton, Oregon, and Hewlett Packard of Palo Alto, California.

California gives major boost to solar energy

A major boost to the US solar energy industry has been given by a ruling from California's Public Utilities Commission that the state's four largest publicly-owned utilities must finance the installation of solar water heaters in 175,000 homes over the next three years.

The utilities — Pacific Gas and Electric Co., Southern California Edison Co., Southern California Gas Co., and San Diego Gas and Electric Co. — have been told to produce plans within 60 days for various types of low interest loans to solar-home owners.

Industry officials estimate that the commission's ruling will increase by more than five times that number of homes in the US with solar-assisted water heating. The plans still require further approval by the commission, and will be the subject of public hearings, but the PUC has indicated that it intends to achieve a major break-through in the acceptance of solar power by consumers.

"Certainly there isn't any question the PUC order is the biggest thing to happen to solar power", said Mr Edward A Myers, vice-president of Southern California Edison. Another utility official claimed that, as far as solar energy was concerned in California, "whether it is economically competitive really doesn't matter any more".

Average cost of installing the solar heaters is expected to be about $2,500 for each house for equipment which would provide 50 to 70% of the energy needed for hot water.

First geothermal plant in Holland

The first geothermal project, part of a larger 32 million guilder energy research and development programme has been started in Holland. Fifty houses in Spijkenisee, a Rotterdam suburb, will be connected in 1982 to a heating system which will circulate water at 100°C from 3000 metres underground. A unique aspect of the system is an interim storage procedure that will hold the water at a depth of 600 metres during the summer months when demand is less. An estimated equivalent of 12-25% of Dutch natural gas reserves is available in geothermal energy. The most favorable source is in the south of the country where studies carried out since 1974 have shown gradients of 40-50° per 1000 metres of depth. **Caspar Schuuring**

US pays radiation exposed veterans

Nineteen war veterans who were deliberately exposed to radiation from bomb tests in Nevada in the 1950s as part of a programme to show that the US fully intended to use its nuclear capability are receiving disability payments for cancer. But the great majority of 493 veterans who have filed claims for cancer contracted as a result of the tests have been turned down. Ten cases were awarded benefits and an additional nine were won on appeal but the Army denied the remaining 386 applications. Other cases are still pending.

UK nuclear inspectorate understaffed

The UK's Nuclear Installations Inspectorate is facing increasing difficulty in meeting its obligations because of government spending cuts. Present staffing is 15% below full complement (17 vacancies out of 104 positions), and recruitment has proved difficult because industrial salaries are 30% higher and because of the Inspectorate's threatened move from London to Lancashire. In addition there are fears that the Health and Safety Executive may be forced to impose non-nuclear duties on its nuclear staff because of the impact of recent budget cuts. Nuclear inpectors are highly specialised and must be qualified engineers with 10 years' industrial experience. Mr Roger Gausden, Chief Inspector, has admitted in the NII's biennial report that "it has not proved possible to recruit the required additional staff to deal with all the tasks facing the Inspectorate".

University of Edinburgh rescinds "six year rule"

The University of Edinburgh has rescinded its rule preventing the rehiring of untenured members of research staff after six years. Citing opposition to the "rigidity" of the rule, a report by a university working party last week said that "research staff are in the best position to make the decisions individually". The report cautions, however, that heads of departments should not make any "unjustified commitments". The "six year rule" has been rescinded "despite the fact that there now appears to be a tendency to adoption of a similar rule by some research

0028-0836/80/08709-01$01.00

councils". The working party, chaired by Professor A G Mackie, surveyed the university non-tenured research staff and found that only half obtained permanent jobs on completion of their contracts, while 11% were unemployed and 32% had moved to other temporary jobs.

UNEP shames Mediterranean countries to pay bills

A MILITANT speech by United Nations Environmental Programme deputy director, Peter Thacher last week (*Nature*, 14 February page 613) has produced promises of payment by the delinquent participants in the Mediterranean clean-up programme. Italy has promised its $745,000 arrears by April, Spain its $412,000 payment by December and France its remaining $573,000 "sometime this year". In addition cheques which have not arrived from Turkey, Yugoslavia and Monaco will be traced. The pollution programme will be forced to close in seven weeks if part of the money is not made good. In another major result at the three day meeting in Barcelona, Algeria signed the 1976 Barcelona pollution accords leaving Albania and Turkey as the only non-signatories. Algeria's signing signals important Third World support for the clean-up programme, expected ultimately to cost $15 billion over 10-20 years.

France and India sign new technical agreement

FRANCE and India have signed seven new protocols for technical and economic cooperation which include research in renewable energies, oceanographic technology, and the development of semi-arid regions of the left bank of the Rajasthan Canal and the Bundelkhandmarea of Uttar Pradesh. Signed by French President Valery Giscard d'Estaing on his visit to India last month, the protocols will also attemt to solve the long standing problem of Franco-Indian cooperation — the inability of India to make use of French credits because of the high cost of French equipment and technical service. **B. Radhakrishna Rao**

Sri Lanka to set up basic research institute

SRI LANKAN President J R Jayawardene announced last week to establish an institute for basic research to be housed at a site near Colombo by November of this year. The culmination of nearly a year of discussions between the President, local scientists, and several expatriate Sri Lankan scientists, the institute will emphasise advanced study in all branches of fundamental science. Professor N C Wickramasinghe, head of the department of mathematics at University College, Cardiff, UK, has been mentioned as a candidate for director of the institute.

FEATURES

Papua New Guinea (PNG) is one of the world's least "developed" countries. A third of its three million people have only emerged from the neolithic age over the past 40 years. The people are divided by mountain ranges reaching 4,700m, torrential rivers, forests, ravines, seas, malarial swamps and language — more than 700 are spoken. But in the five years since independence from Australia, the government has launched an ambitious Improvement Plan, under which western science and technology are being introduced enthusiastically. All projects are funded by the National Public Expenditure Plan, which absorbs 21% of all spending. The main national aims are equal distribution of development among a population that is 85% rural and largely dependent on subsistence farming and a reduction in the number of western expatriates on whom development still largely depends. Both aims are meeting with mixed results, as **Tony Ades** reports

Appropriate technology:

PAPUA New Guinea's Eight Point Improvement Plan calls for self-reliance, less dependence for its needs on imported goods and services. Most conspicuous among imported services are those of the 4,200 expatriates employed by the government. While nearly all political posts are filled by nationals, expatriates have a dominant role in formulating policy and planning its execution.

Since self-government in 1973 the number of expatriates has fallen from 50,000 to 30,000, partly as a result of the localisation programme, the replacement of expatriates by nationals. In the public service, the proportion of expatriates has dropped by 10%, but there seems to be no hurry to enforce the planned 4% reduction per year because the number of qualified nationals is not increasing as fast as the nation's need for skilled administrators.

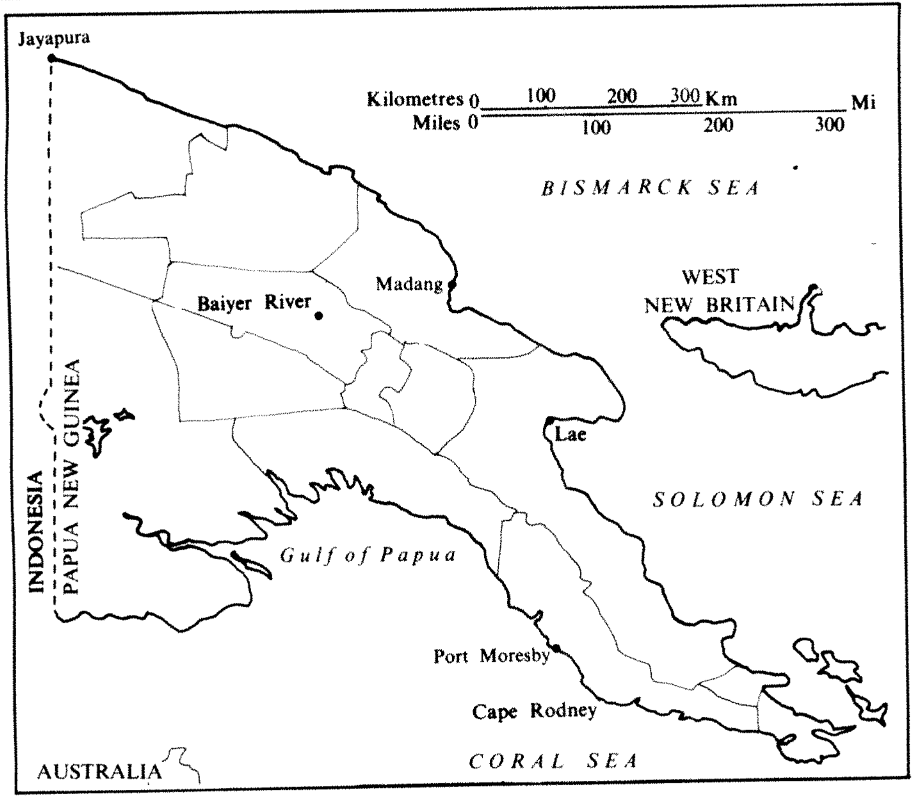
There are sound economic reasons for localisation. The average expatriate costs the government four or five times as much as the average national, and even at the same level the expatriate will earn between two and three times more. Also, their incomparably higher standard of living creates unfulfillable hopes in the local population. However, unlike most developing countries, PNG had no western-trained elite to take over at independence. Furthermore, the sheer inaccessibility of much of the country has brought education very unevenly. In the highlands, where many gratefully recall how the first Europeans ended interclan fighting after the Second War, people are inclined to believe that localisation has been going too fast, leaving them permanently disadvantaged to the coastal peoples whose longer contact with the West and higher levels of education give them disproportionate political power.

Of all government services it is in fact education where localisation has been most dramatic. By 1972 all primary school teachers were nationals. Since then the number of teachers has doubled to 10,000. And although 60% of all children now attend primary school, there has been a serious fall in standards that will take many years to work itself out of the system. In the meantime, localisation of secondary school teaching is going ahead.

The standards problem is most severe in science and mathematics. Complaints that young men and women training to be Health Extension Officers or agriculture technicians cannot calculate drug dosages or areas are commonly expressed, and at all higher education institutions students take remedial maths courses that may delay their regular curriculum by up to a year. Whatever the economic and political advantages of localisation, PNG's ambitious plans for development demand so much gathering of data on every aspect of the land and population, and so much administration, that many are asking whether localisation too early has actually increased dependence on expatriates.

Tony Ades has a Nature writing fellowship and is currently at the PNG Institute for Medical Research, on leave from Sussex University, UK.

0028-0836/80/08710-03$01.00



Papua New Guinea's view

An expansion of education and a consequent fall in average standards is not unusual in developing nations. In PNG it has lead to demands, particularly from expatriate education planners, that a more merit-oriented system be introduced. At present, selection from one level of school to the next is based on a quota system biased toward children from lower quality schools and poorer regions. This policy is typical of the government's determination to redress regional imbalances. The government is equally unlikely to yield to suggestions that it drop its plan for 100% primary school enrolment by 1990, on the grounds that vitally needed extension services in health and agriculture are seriously hampered by illiteracy.

The concern for equality, rather than higher levels of education for a few, was based on the idea that PNG would adopt small-scale, labour intensive modes of development. At the time of independence there was a corresponding enthusiasm for "appropriate technology". But the Village Task Force, set up in 1974 to carry this through to the rural people, seldom progressed beyond the theoretical stage. Six years later, the South Pacific Appropriate Technology Foundation (SPATF) acts as an information clearing house and sets up small projects like village water supplies, but is still very limited in its capacity to create rural employment. Instead, SPATF has been set to work on the urban unemployment problem, and devises pilot projects such as furniture making.

Its research arm, The Appropriate Technology Development Unit at the University of Technology, Lae, is also more oriented towards hardware. It has designed a hydraulic ram pump that can be built with a drill press rather than an entire machine shop and is currently testing mini-hydroelectric schemes. The newly appointed Vice-Chancellor, Professor Alan Mead, has promised to involve more of the somewhat reluctant faculty in this type of work, but there exists as yet no channel by which rural needs and technical possibilities can meet each other.

SPATF's explicit policy of "not telling people what they want" demands that people have some idea of what is available. It has always been hoped that the increasing number of school leavers, teachers, extension workers, and even some university graduates would return to their villages and catalyse development. But those few who try are often rejected by the village elders. Extension workers are now generally posted away from their own villages, losing the advantages of shared language and culture. On top of this, a western education, even if below western standards, does not prepare one for a return to a subsistence lifestyle. A student at the University of Technology told me that he might eventually go back to his village, but only when electricity had reached it and when television broadcasting had begun. Then he would help the village develop by selling and servicing television sets. Such views are not unusual.

The fact is that the "appropriate technology" emphasis on locally available materials and skills, and on the natural evolution of simple technologies at the hands of the craftsmen who use them, is scarcely relevant in a country with no traditions in metal, cloth or draught animals. For many the first wheel came on an aeroplane. The arrival of science and technology has been headlong: generally it is capital intensive and oriented to a high return. Papua New Guineans have welcomed sophisticated telecommunications, the F-28 jets flown by Air Niugini, and the highly sought after four-wheel drive land vehicles. And at the government level there is certainly room to doubt the commitment to appropriate technology. In spite of the recommendations in its own national paper to last years United Nations Conference on Science and Technology for Development, PNG operates no assessment or vetting of imported technical hardware.

On the other hand, in the field of energy, PNG enters the technological age with more foresight than any developed nation, and with a comprehensive policy aimed at self-sufficiency through renewable resources. The present expansion of the road system and the growing monetarisation is forcing up fuel imports at 8% a year. To counter this the initial step is to be a cassava-to-alcohol conversion plant in the Baiyer River area of Western Highlands Province. The 2 million litres produced each year will be mixed at 15-20% with motor spirit. The plant will be in a remote area not only to bring rural employment, but also to offset government subsidies for fuel transport costs, which run to K3.50 ($4.62) per gallon in the most inaccessible regions. (One PNG kina is worth $1.32.) If this conversion plant is a success, more will be built. It is hoped that the use of alcohol fuels will eventually reach a level that would justify the import of cars that run on 100% alcohol. At that point large scale wood-to-alcohol installations would be built, drawing on waste from forestry operations.

PNG has so far decided against rural electrification. Other aspects of the energy policy include pilot projects for charcoal production, wood pyrolysis, firewood cropping, together with research into solar air conditioning, sago to alcohol conversion, and biogas plants. Meanwhile, several small diesel generators are to be replaced with photovoltaics. The entire programme, the brainchild of Dr Kenneth Newcombe at the Department of Minerals and Energy combines all levels of technology with a sensitivity to rural skills and needs. It is also an outstanding example of how much scope expatriate scientists and economists have in moulding the course of PNG's development towards, paradoxically, self-reliance.

While many components of the energy policy accord with official approval of small-scale industry, and are therefore consistent with the educational system's stress on quantity rather than quality, the course of development appears to be moving in the other direction, calling for more skilled management than is available. A shift away from smallholder projects is becoming evident. For example, cattle smallholdings are to be replaced with ranches owned by entire clans, worked by hired labour and large enough to pay the services of an expatriate manager. A flagging smallholder rubber development at Cape Rodney, Central Province, is to be revitalised by the addition of a central estate. The World Bank's Southern Highlands Development scheme also opts for nuclear estates. The Baiyer River alcohol plant will be supplied with intensively farmed cassava. The rice and sugar projects now under consideration not only have no place for smallholders, but are on a very large scale indeed.

The causes of this trend go deeper than economies of scale and the unstable output of smallholders. Officials concede that there has been insufficient effort to make the smallholder self-reliant. Extension officers have arranged for bank loans to farmers and taken most of the decisions to ensure that the loans are repaid. Effectively the smallholder is turned into a labourer on a government-managed farm. On top of this is the difficulty of extension work among a largely illiterate population with a chronic shortage of staff. Yet the government is committing only K300,000 ($396,000) a year to adult literacy programmes. Moreover, Rural Development Assistants, who comprise the vast majority of agricultural extension staff, are to be phased out altogether. They will eventually be replaced with smaller numbers of better-trained staff, but an increasing proportion of students graduating from agricultural colleges go into private business for themselves.

Eventually, the educational system will probably iron out the currently erratic course of development at the rural level, if, that is, its western orientation does not promote dissatisfaction with rural life. However, it may be perpetuating the lack of local expertise which recently lead the Prime Minister Mr Michael Somare to try to drum up Australian investment. PNG is not at the mercy of foreign capital. Its laws clearly demarcate the areas in which investment is welcome, and it regulates the form that foreign business activities can take. But critics point out that this can only serve to amplify the gap between the still expanding subsistence population and the wage sector, and further disrupt the former.

In addition to this, the growing indigenous commercial interests, with their increasing political influence at provincial level, are also aiding the push towards a more capital intensive wage sector and away from subsistence and smallholder farmer. A related danger is that provincial governments are threatening to make their own arrangements with foreign companies, but have less ability to ensure favourable terms than the national government.

In accordance with its stated policies, Papua New Guinea is slowly achieving self-relieance as a nation, and redressing the inequalities between its regions. The question is: can it at the same time bring self-reliance and equality to its people? □

Depending on foreigners for self-reliance: expatriate manager (right) with cattle smallholders rigged out in clan gear

Eric Ashby (right) looks at a recent report on public participation in technology decision-making in OECD countries and argues that better public information could reduce disenchantment with representative democracy

THE WINDSCALE enquiry in Britain and the Mackenzie Valley Pipeline enquiry in Canada were highly publicised experiments in participation. They were responses to a demand which has now become insistent, for "a greater degree of public accountability, freer public access to technical information, more timely consultation on policy options, and a more holistic approach to the assessments of impacts", to quote a report on participation from the Science Policy Division of the Organisation for Economic Co-operation and Development.

The report, *Technology on Trial*, by K. Guild Nichols, published in Paris last year, is a clear and useful account of the present state of the art of participation in OECD countries. The important point Nichols makes is that this demand is a symptom of a much deeper social disturbance — a disenchantment with the whole process of representative democracy.

The public elect people to represent their interests and straightway distrust them. Through the mass media self-appointed leaders who claim to represent the public interest can bypass the traditional hierarchy of procedure and appeal direct to the people over the heads of legislators. Nichols quotes Paul Valery: 'all politics is based on the indifference of most of those concerned, without which politics would be impossible'. If Valery was right, we are in for trouble; for concern, as measured by the number of people prepared to vote (for instance) in the referendum on atomic power held in Austria in November 1978, is spreading, and indifference to such great issues can no longer be assumed by those who make decisions.

Governments in pluralistic democracies are embarrassed by this surge of interest; as indeed they need to be, for this desire that the general public should participate in the decisions that affect their lives is undeniable in theory and confoundedly perplexing in practice. There is no such thing as monolithic public opinion. Even groups of people who agree about what is in 'the public interest' may do so for different reasons: one because he genuinely fears a nuclear economy; the other because he doesn't want a power station to spoil his view. The utilitarian calculus — that a social welfare function is the sum of a multitude of individual welfare functions — is a discarded and useless concept. The assumption, accepted for a long time by the man-in-the-street, that major

0028-0836/80/08712-02$01.00

Participating in planning: the public needs better information

technological problems can be left to experts to solve, is no longer valid. If we want to remain a pluralistic democracy, we have got to invent reliable machinery for public participation.

Nichols' essay describes how information on technological issues is conveyed to, and elicited from, the public; and he describes how policy makers are informed and advised. He draws examples from several countries: Britain, the US, Canada, Scandinavia, Germany, Austria, France. He picks out the difficulties and displays them clearly. How can an unofficial group of citizens get access to the necessary information? Where can they raise the money to dispute a governmental policy? How can state officials, promoting what they earnestly believe is the public interest, be protected from vexatious, and sometimes mischievous, obstruction from groups acting out of self-interest? What are the comparative merits of agencies, legislative hearings, commissions, and the courts, as ways to resolve conflicts of values?

Nichols gives an accurate and objective summary of recent attempts in OECD countries to reconcile the conflicts of fact and value which are inevitable when nations have to make decisions about exploiting the environment. In just over 100 pages he could not be expected to cover the whole range of social experimentation that has been tried. This range has been classified, somewhat tendentiously, by S.R. Arnstein (in *The Journal of the American Institute of Planners*, xxxv, 1969, p.216) in six categories, grouped in pairs: (i) manipulation and (ii) therapy (designed to 'cure' the participants of what the proponents of a scheme deem to be ignorant prejudice); (iii) providing information and (iv) consultation (deemed by some participants to be 'tokenism'); (v) delegated power to participants and (vi) citizen control (the two categories which Arnstein is prepared to regard as 'partnership'). Categories (i) and (ii) have been rejected by the lobbies which give themselves the duty of scrutinising the impact of technologies on the environment. As machines for public participation they are obselete. Category (vi) would be regarded, by all but the most fanatical opponent of representative government, as unrealistic. Categories (iii) and (iv) are acceptable to some lobbies, and they could be made more widely acceptable if they were taken more seriously by governments.

For models of intelligent consultation combined with masterly presentation of facts we have to turn to Canada. Two outstanding examples are the reports of Mr Justice Berger on the gas pipeline from Alaska (summarised by Nichols); and the outstanding report from the Ontario Royal Commission on Electric Power Planning (*A Race Against Time: interim report on nuclear power in Ontario*, Toronto, 1978). The explanation of the CANDU fuel cycle in this report is a brilliant example of interpretation to the layman of the issues he must understand before he can play a useful part in any process of participation.

The corporation that generates electricity — the Ontario Hydro — has no statutory requirement to involve the public in its planning processes. Nevertheless, since 1972, the corporation has involved about a hundred people at head office and in its regions, holding public hearings, setting up citizens' committees, and listening to anyone who cared to talk to them.

Whether this has educated the public to understand the issues better is something that cannot be proved; but there is no doubt that the public have educated Ontario Hydro, and the Commission.

This, however, falls short of partnership in decision-making, and there are very few examples of the delegation of some power to the participants, Arnstein's category (v). Only one successful example of that is on record. It is to be found in a report prepared for the Electric Power Research Institute in California (*Proceedings of a Workshop on the Measure of Intangible Environmental Impacts*, EPRI Special Report, Palo Alto, 1976). The San Diego Gas and Electric Company had to site a new power station in southern California. They invited the public to set up a committee of their own to examine alternative sites, provided them with financial help and expert advice, and left them alone to hold their own public hearings and to make a recommendation, which the Company accepted.

It is unlikely that participation in Britain will go beyond the levels of Arnstein's categories (iii) and (iv) in the foreseeable future; but if bodies like the Central Electricity Generating Board and the National Coal Board bring imagination and genuine enthusiasm to their schemes for providing information and for seeking consultation, the benefits even of limited participation could be considerable. First, it could restore some confidence in the judgement of those who inevitably have to make the final decisions (the process of decision-making is as important for society as is the wisdom of the decision itself). Second, it could encourage a sense of responsibility among the so-called public interest lobbies.

More participation will not necessarily clarify the issues themselves: indeed one of the surprising results of a massive experiment in public education about nuclear power in Sweden, financed from public funds and involving some 80,000 members of the public, was that at the end the number of people who felt unable to decide either for or against nuclear power *increased* from 63% to 73%. This is not — as some government officials asserted — a sign that the experiment failed; it is, rather, a sign that more people than before are aware of the immense complexity of the problems facing their representatives in government. This could increase public sympathy with decision-makers; and this in turn could help to turn the tide of disenchantment with representative democracy.

Our educational system must bear some of the blame for this disenchantment. In the last thirty years the impact of science on society has gone up by many orders of magnitude; but science at the popular level (for those who are not going to become professionals) is taught in very much the same old way.

We have not paid enough attention to telling people what they need to know about science if they are to perform their civic duties. (Often we tell people too much: Nichols quotes Thurber's little girl: "This book tells me more about elephants than I ever wanted to know".) The American science writer Philip Ritterbush put the challenge this way: '. . . scientific understanding of the public, rather than public understanding of science, might become the frame for discourse'. ☐

CORRESPONDENCE

Biotechnology and scientific collaboration

SIR, — In a recent issue of *Nature* (10 January, page 125) I was pleased to note in Robert Walgate's article the inclusion in the proposed EEC programme on biotechnology of "development of reactors for reactions at a hydro-organic interface", since our Biotechnology Unit has been responsible for several PhD theses and published papers related to this topic. The unit, set up several years ago, did effectively organise collaboration between biochemists, chemical engineers and microbiologists in this and other fields.

It was therefore surprising to read on the following page that "Lilly's group is unique in the UK in combining chemical engineers and biologists". While this group has indeed been pre-eminent in developing recognition of enzyme technology in this country, Dr Walgate could have ascertained that it was not unique, by reading the 1976 Report to the SRC and Institution of Chemical Engineers by A.N. Emery which cites at least four UK universities where such collaboration occurs.

A point of more concern is evidence of conceptual isolation of food science from biotechnology. Both involve application of the same basic disciplines of biochemistry, microbiology and chemical engineering and are similarly concerned with the provision, processing and utilisation of natural products. Both involve enzyme technology. This isolation is surely based more on territorial tribalism among applied scientists and their professional organisations than on a rational approach to the subject matter.

Now that the universities have entered lean years, where the relationships between the financial bones and the semantic skins are more carefully scrutinised, it is to be hoped that the various bodies concerned with biotechnological planning will not take too narrow a view of existing and potential assets.

Yours faithfully,

J.A. BLAIN

University of Strathclyde, Glasgow, UK

FAST's biotechnology programme

SIR, — Your issue of 10 January focusing on biotechnology was timely and relevant, in emphasising that "the middle-term problem rests with governments", and that "this is precisely the moment when patterns of research will be formed which will ultimately shape lives". The Commission's "FAST" programme (Forecasting and Assessment in the field of Science and Technology) was set up by decision of the Council of Ministers to highlight prospects, problems and potential conflicts likely to affect long-term development of the Community and define alternative courses of Community research and development action.

Biotechnology — or more broadly, a "bio-society" scenario — has been selected as one of our three central themes, and within this we shall be sponsoring a number of research studies covering such related long-term issues as Community research and development strategy, manpower and training implications, social acceptability, Third World implications, and environmental engineering; further details are available on request.

I should point out that the FAST programme is distinct from the biomolecular engineering programme described in your issue of 10 January, though naturally we have the benefit of collaboration with our Commission colleagues, both from this programme and elsewhere in the Commission.

Yours faithfully,

MARK F. CANTLEY

Commission of the European Communities, Brussels

Shortage of science teachers

SIR, — It is reported in *Nature* (17 January, page 233) that there are serious shortages of teachers of mathematics and natural sciences, particularly physics, and it is revealed that of our secondary school teachers of physics only 43% are qualified to teach physics. Your report contains the wise and timely warning, "without well-qualified science teachers, there is little hope for the future of science and engineering in Britain". I wish to present the case that the situation is in fact even more serious than the figures suggest.

Firstly, I question the suitability of the education of many (or probably, most) of those who *are* "qualified to teach physics". University graduates generally have acquired an imperfect knowledge of advanced work in a specialist subject. To teach physics in school one requires a very thorough understanding of the elementary principles of the science, and also considerable knowledge of the relationship between physics and other subjects.

Secondly, there is a tacit assumption in all educational thinking that teachers and pupils can easily obtain trustworthy information about any subject by reading textbooks. It is now 20 years since the writer first drew attention to the incredible accuracy of very many physics textbooks, particularly at sixth form level. During the past 20 years a very few publishers have attempted to improve their own books, but the general standard has continued to decline.

As it is obvious that we cannot quickly remedy the shortage of suitably trained teachers, surely it is obvious that we must help the teachers we have by ensuring that they have accurate sources of information.

Yours faithfully,

J.W. WARREN

Brunel University, Uxbridge, Middlesex, UK

Brazil's fuel technology

SIR, — I was very interested in the article on alternative fuel technology in Brazil (6 December, page 550) which you published recently. Unfortunately, in the discussion of ethanol production, the author did not answer the one question which seems to me the most important in this whole project. Where does the fuel come from to distil the ethanol? By fermentation, ethanol can only be produced in dilute aqueous solution, and the amount of energy needed to fractionally distil this may be greater than the energy obtained from burning the ethanol.

It seems to me that this need for an energy input to fractionate the ethanol may be a fatal weakness in the whole ethanol project. It is avoided by the use of methanol, which is not produced in dilute solution, and may be made, for example, from wood *via* charcoal.

Yours faithfully,

DAVID A.H. TAYLOR

University of Natal, Durban, Natal

Nuclear power

SIR, — There seems to have been a serious misprint in the penultimate paragraph of the article on *Nuclear Power: the threat to personal freedom* in the 20-27 December issue (page 774). The paragraph states that the pursuit of nuclear power could conceivably damage civil liberties less than would the pursuit of a high conservation/low energy strategy as outlined earlier this year by the International Institute for Environment and Development. Since the IIED strategy does not touch personal liberties and at most calls for mandatory targets to be set for the energy performance of products such as cars and new buildings, thus merely altering the range of consumer choice in one respect, the paragraph is clearly back to front. Energy conservation may have to be forced through by 'controls' on individuals only if we do 'too little, too late'; but no critic has yet accused the IIED scenario of that! And even controls of this kind are a long way from armed police and security vetting.

Yours faithfully,

GERALD LEACH

International Institute for Environment & Development, London, UK

Job-swapping

SIR, — In regard to your editorial on job-swapping (4 October, page 327), I had the good fortune to exchange jobs and houses with a librarian in Scotland for an academic year and would do it again eagerly.

It did, however, require a fairly substantial amount for travel expenses and salaries, which therefore were paid by our home institutions. I think your point about the necessity for a 3-5 year tenure is unnecessary and, on the contrary, for family reasons, I would suggest a 2-3 year exchange.

Yours faithfully,

DANA L. ROTH

California Institute of Technology, Pasadena, US

New Jersey Turnpike

SIR, — Robert Claiborne (20/27 December, page 776) says that my "attitude to facts is not beyond criticism", but his basis for this statement is manufactured out of context. I said that on a specific occasion the odors and visual obscuration ("like twilight or an eclipse of the sun") described in the book did not occur. The book implied (p102) that this alleged nuisance, caused by the large petrochemical complex near the New Jersey Turnpike, is not even occasionally abated. I lived near the complex for 21 years, and the statement in the book is incorrect.

Yours faithfully,

THOMAS H. JUKES

University of California, Berkeley, US

NEWS AND VIEWS

Physics at very high pressures with laser-driven shock waves

from M.H. Key

RECENT papers by Trainor *et al.* (*Phys. Rev. Lett.* **42,** 1154; 1979) and by Veeser *et al.* (*Appl. Phys. Lett.* **35,** 761; 1979) highlight the fact that in relatively simple experiments laser-driven shock waves can be used to study the propagation of shocks in solids for shock pressures up to terapascals (1 TPa = 10^7 bar = 10^{13} dyne cm^{-2}). In view of the fact that the only demonstrated alternative for studying such high pressure shock waves requires a nuclear explosion (Ragan *et al. JAP* **48,** 2860; 1977) the simplification provided by the laser approach is considerable.

Laser irradiation of a solid surface in vacuum creates a high pressure surface plasma. The pressure exerted on the solid by this 'ablation plasma' is shown in Fig. 1 as a function of laser irradiance I and for two laser wavelengths $\lambda = 0.53$ and 1.05μm. The ablation pressure acts as a 'piston' driving a shock wave into the undisturbed solid. Accurate shock velocity measurements were obtained by Trainor *et al.* and Veeser *et al.* by recording the differential time of transit of the shock through ~30 μm thick foil targets with a step variation in thickness as in Fig. 2. The arrival of the shock at the rear surface was signalled by a fast (~10^{-11} s) rise in luminosity detected by an electron optical streak camera with time resolution ~10^{-11} s.

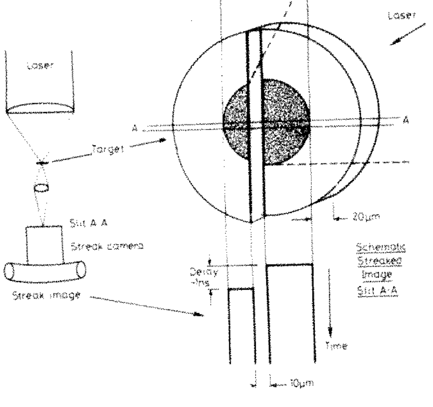

Fig. 2 Schematic diagram showing how streak photography is used to measure shock velocity in a planar foil target with a thickness discontinuity.

The maximum shock pressure for which these techniques are useful is limited by the saturation in the rate of increase of ablation pressure with intensity (Fig. 1) and the associated increasing depth and magnitude of target preheating due to energetic electrons generated in the process of absorption of the laser light in the surface plasma. Where pressure due to this preheating becomes significant relative to the ablation pressure and the preheat penetration depth becomes comparable with the target thickness the process no longer results in a simple shock propagating in an undisturbed medium. Investigation has shown that the preheating depth is a function of $I\lambda^2$ and that the maximum value of $I\lambda^2$ for simple shock generation in these targets is of the order of 3×10^{14} W cm^{-2} μm^2 (Hares *et al. Phys. Rev. Lett.* **42,** 1216; 1979). Thus shock pressures up to 1.8 TPa were reported by Trainor *et al.* using 1.06 μm radiation while Fig. 1 suggests that with $\lambda = 0.53$ μm pressures up to about 10 TPa should be attainable.

The motivation for these studies is that the equation of state of compressed solids is not well known in the interval between a few tenths and a few tens of terapascals. At lower pressures extensive experimental data from static high pressure and chemical explosive experiments are available while at higher pressures the relatively simple Thomas Fermi (TF) theoretical model is valid (Ragan *et al. op. cit.*). The TF model neglects all atomic structure and quantum mechanical binding force between atoms and treats only the compressibility of a degenerate electron gas in the field of positive nuclei. At the opposite extreme a solid at zero pressure is in equilibrium between the degenerate electron repulsive forces and interatomic binding forces. Theoretical analysis for conditions where the applied pressure is not large relative to the binding forces is complex and experimental studies are needed.

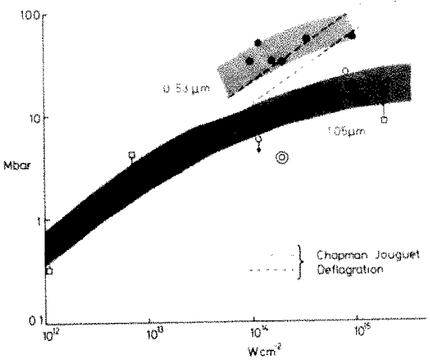

Fig. 1 Ablation pressure in units of megabar as a function of laser irradiance for 0.53 and 1.05 μm laser wavelength. (Dashed lines theoretical model). Unpublished results obtained by research groups from Imperial College London and Queen's University, Belfast working at the SRC Central Laser Facility, Rutherford Laboratory.

The laser technique of shock generation extends the upper pressure limit for such measurements since measurement of any two of the five shock parameters (material density, pressure, internal energy, flow velocity and shock front velocity) allows solution for the other three (from the conservation of energy momentum and mass flow across the shock front) and hence gives the equation of state relationships between pressure, density and internal energy (Ragan *et al. op. cit.*).

M.H. Key is at the Rutherford Laboratory.

Intermediate filament cycles

from Brian Anderton

RESEARCH into the structure and organisation of the distinct fibrous organelles which make up the cytoskeleton of eukaryotic cells has intensified enormously in the past four or five years. The latest component of the cytoskeleton to come under close scrutiny is the intermediate filament. Intermediate filaments are approximately 10 nm in diameter and are so called because their width lies between those of the other two cytoskeletal fibres, microtubules (24 nm) and microfilaments (6 nm). Unlike tubulin and actin, which are the principal structural proteins of microtubules and microfilaments respectively, intermediate filament proteins seem not to be highly conserved and show a certain degree of tissue specificity. They have been divided into subclasses on the basis of biochemical and immunochemical data and with the inevitable consequence of isolation, the constituent proteins have been given names (in some cases more than one).

Five subclasses have been identified and new ones may need to be added. So far the (roughly tissue-specific) subclasses comprise (1) prekeratin tonofilaments of epithelial cells; (2) desmin or skeletin filaments of smooth muscle which are also identified with the protein present in the z-line region of cardiac and skeletal muscle; (3) filaments of fibroblasts and other mesenchymal cells (vimentin or decamin); (4) neurofilaments of neurones; and (5) glial filaments (glial fibrillary acidic protein) present in astrocytes (but not other glial cells). Structural homologies between different intermediate filaments have only occasionally been sought but some do seem to exist (Gard *et al. Proc. natn. Acad. Sci. U.S.A.* **76**, 3894; 1979; Steinert *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 6098; 1978).

The biochemical characterisation of different intermediate filaments has been hampered by the fact that when isolated they are mostly insoluble in salt solutions. This unfortunate physical behaviour from the point of view of the biochemist now seems to have been overcome by Zackroff and Goldman (*Proc. natn. Acad. Sci. U.S.A.* **76**, 6226; 1979). Goldman and his colleagues have for some time been studying the fibroblast intermediate filaments from cells of the baby hamster kidney line BHK-21 and have shown that the main constituents are two polypeptides with chain weights of 54,000 and 55,000 which they have called decamin. In their latest paper they report a detailed investigation of an earlier observation that BHK-21 intermediate filaments disassemble on prolonged exposure to solutions of low ionic strength at around neutral *p*H and reassemble on returning the protein to physiological ionic strength. When disassembled the material seems to consist of short rods or protofilaments perhaps 50 nm long and about half the width of an intermediate filament; the authors make no estimate as to the number of polypeptides constituting a single protofilament.

Turbidimetric measurements during reassembly show the process to be biphasic. Examination by electron microscopy suggests initial lateral association of the short thin rods to produce short thick rods followed by elongation of the latter to give apparently reconstituted intermediate filaments. The assembly process exhibits a critical protein concentration for initiation in the range 0.05–0.15 mg ml^{-1}. Possibly the most significant aspect of the work is the discovery that cycles of disassembly/reassembly can be achieved, although protein recovery seems problematical, and that after two such cycles the stoichiometry of the 54K and 55K polypeptides seems to remain around unity and several high molecular weight proteins above 250,000 copurify with the decamin polypeptides. This approach of inducing cycles of polymerisation/depolymerisation has been used successfully for purifying tubulin and identifying microtubule-associated proteins which remain in a constant weight ratio to the tubulin through repeated cycles. No doubt this report from Goldman's laboratory will now encourage others to apply the same technique in attempts to define the molecular composition of intermediate filaments from different sources. It should be pointed out, however, that Zackroff and Goldman believe the large decamin-associated polypeptides not to be essential for intermediate filament assembly since their removal by mild proteolysis does not block polymerisation of the 54K and 55K decamin polypeptides.

It remains to be seen whether or not the BHK-21 fibroblast intermediate filaments are heteropolymers of the 54K and 55K chains or if homopolymers of each exist separately inside the cell. Lazarides and colleagues have suggested that muscle intermediate filament protein, which they call desmin, is not restricted to muscle in its distribution but is also found in non-muscle cells such as fibroblasts, including BHK-21 cells (*Proc. natn. Acad. Sci. U.S.A.* **76**, 3894; 1979). They have assigned the 54K polypeptide from BHK-21 cells to desmin and the 55K polypeptide to the true fibroblast intermediate filament protein. They have also recently claimed that fibroblast intermediate filament protein too is more widely distributed than hitherto assumed and that it occurs along with desmin in the myofibril z-disc (*Cell* **18**, 1053; 1979). Notwithstanding earlier reports that desmin was absent from non-muscle cells, these more recent data seem convincing and are analogous to the results from Franke's, Weber's and Osborn's laboratories which show that epithelial cells also contain two types of intermediate filament, namely prekeratin tonofilaments and fibroblast intermediate filaments for which they use the name vimentin filaments (*Differentiation* **14**, 35; 1979). However, more studies are needed as the BHK-21 cell line may not be typical. It is unclear, for instance, whether mouse 3T3 cells contain two types of intermediate filament polypeptide as published electrophoretic patterns (Franke *et al. op. cit.*) of purified intermediate filament protein from these latter cells show a single prominent polypeptide and not a doublet like that found from the BHK-21 cells.

Although such ambiguities remain, the classes and distribution of intermediate filaments are now beginning to fall into a pattern although we remain mostly in the dark as to their function. Probably the predominant view is that they are important in maintaining cell shape and the spatial organisation of other intracellular structures. However, now that they promise to be amenable to biochemical investigations of the type used by Zackroff and Goldman, their lack of established function is unlikely to deter the protein biochemists. □

Brian Anderton is a lecturer in the Department of Immunology, St. George's Hospital Medical School, London.

Kimberlite and carbonatite magmas

from K. G. Cox

THE Earth's crust is a relatively thin layer made up of familiar rocks similar to those seen at the surface. However, at a depth of about 10 km in oceanic areas and at 50 km beneath the continents a sudden increase in the velocity of seismic waves marks a fundamental change of structure. From here downwards, to the outer edge of the core at a depth of about 3,000 km, the rocks are referred to as the mantle. This is volumetrically by far the largest compositional component of the Earth but relatively little of a direct nature is known about it. The mantle 50 km below our feet is distinctly less accessible than the Moon. Apart from the very uppermost levels of the mantle, which are occasionally exposed at the surface as a result of violent continental collisions, the only samples available are brought to the surface as fragments ('nodules') suspended in magma during volcanic activity. The distinctly rare volcanoes known as kimberlite pipes, which of course also supply diamonds, are the richest source of such materials.

At a recent meeting in London* J.B. Dawson (University of Sheffield) gave an authoritative review of the present state of knowledge of upper mantle rocks derived as nodules from kimberlite pipes, largely from southern Africa.

---

*The Anniversary Meeting of the Mineralogical Society, held in London on 10 January focused on the petrology of mantle materials and deep-seated magmas such as kimberlite and carbonatite.

0028-0836/80/08716-02$01.00

The most abundant nodule type is a very magnesium-rich silicate rock termed garnet peridotite and consisting largely of the minerals olivine and enstatite with smaller amounts of garnet and diopside. A distinction can be made between peridotites which are 'fertile' as opposed to 'barren', by which is meant their capacity to give rise to basaltic silicate liquids, the most common surface manifestations of volcanic activity. Barren peridotites are depleted in the low melting components calcium and aluminium, poor in garnet and diopside as a consequence, and seem therefore already to have undergone melting episodes to give rise to basalts. Most of the upper mantle sampled by kimberlites seems to be of this type and has evidently been involved in the melting processes of the past by which the crust has become separated from the mantle.

A distinction is also made between sheared and unsheared peridotite nodules. The former provide evidence of deformational events within the mantle, and it was postulated some years ago that they represented samples of the asthenosphere, that is the supposed layer of mobile mantle underlying the Earth's rigid surface plates. However plate motions as measured by rates of continental drift seem to be far too slow to account for the very strong deformational fabrics observed, and current opinion is drifting towards an alternative theory that the deformation is purely local and connected with the uprise of the kimberlite magma itself.

The study of nodules is the most direct way of obtaining information about the mantle. However many volcanic rocks are the solidified products of melts which originated in the mantle, and so provide another important approach to mantle problems. As well as kimberlite the extraordinary igneous rocks known as carbonatites are an important source of information. These are unique in that they solidify from carbonate, not silicate, melts. The session on kimberlite and carbonatite magmas tackled first the question of whether the two were related. Kimberlites occasionally contain a good deal of magmatic carbonate, both sorts of magmas are emplaced as relatively small intrusions in continental areas and occasionally show a fairly close relation in space and time and both are characterised by concentrations of relatively rare elements. R.H. Mitchell (Lakehead University, Ontario) maintained that because spinel mineral compositions in kimberlites and carbonatites are different the idea of a petrogenetic relation between the two rock types is not supported. S.E. Haggerty and B.M. McMahon (University of Massachusetts, Amherst) disagree, concentrating on mineralogical evidence suggesting that magmatic calcium carbonate was an integral part of kimberlite. Clearly at this stage a definition of what is meant by the term carbonatite is required. Does for example the carbonate component within kimberlite count as carbonatite, or is it simply carbonate? However the lack of definition on this topic is probably less important than the failure to define what is meant by the term petrogenetic relationship. The relationship could consist of a common source material, a common magmatic precursor, a common thermal or deformational event, the exploitation of a common structural weakness in the crust, or some combination of these. W.J. Verwoerd (University of Stellenbosch, S. Africa) in describing the remarkable sequences of aligned intrusions in Angola, S.W. Africa/Nambia and the western part of Cape Province suggested perhaps wisely in view of the complexity of the question, that possibly the only common factor relating the kimberlites and carbonatites in this area was their exploitation of the same structural features. In areas where kimberlites and carbonatites are less common, for example in south east Australia as reviewed by J. Ferguson (Bureau of Mineral Resources, Canberra) and in N. America as reviewed by H.O.A. Meyer (Purdue University, Indiana) any relationship between the two rock types is difficult to find. However the rather close spatial and time relationship between the Murfreesboro kimberlite and the Magnet Cove carbonatite in Arkansas remains an intriguing coincidence.

Concerning the generation of kimberlite magmas D.K. Bailey (University of Reading) produced an ingenious and stimulating hypothesis. He pointed out that continental geotherms (distribution of temperature with depth) deduced from kimberlite nodules from different localities were all closely similar and that these could lie in 'grazing coincidence' with vapour-saturated solidi (onset of melting curves) of mantle rocks. Thus the introduction of fluids (such as water) under such conditions could initiate melting in a very restricted depth range and give rise to kimberlite magmas. Such magmas can only reach the surface if they erupt very rapidly since any attempt to migrate slowly upwards while losing heat results in their solidification. If the thermal gradient is lower than the critical value no melting occurs. On the other hand if it is higher, melting starts at a lower level and the magmas can migrate upwards without immediate solidification, interact with overlying mantle and lose their kimberlitic character. Bailey thus proposes that "kimberlite activity is the limiting case of cratonic magmatism".

On the subject of carbonatites I.C. Freestone and D.L. Hamilton (University of Manchester) reported successful experiments demonstrating immiscibility between natural soda-rich silicate liquids (phonolite and nephelinite) and natural alkali carbonatite. M.J. Le Bas (University of Leicester) also stressed the importance of alkalis in carbonatites pointing out that deduced compositions of fenitising fluids (fluids which transform wall-rocks) and observed compositions of fluid inclusions in calcic carbonates agreed in indicating a significant alkali-metal content.

Much presented at the meeting gave food for thought but probably nothing more so than the account by A.R. Woolley (British Museum) of his re-mapping of the Alnö carbonatite complex. Brogger's work on Fen and von Eckermann's on Alnö are the historical foundations of carbonatite geology, and yet von Eckermann seems to have been wrong on many important points. However, wrong though von Eckermann may have been, he did recognise many important phenomena and that the carbonates were igneous not sedimentary, so Alnö played its part in the development of the science notwithstanding. □

Antigravity?

from P.C.W. Davies

NEUTRALISING the effects of gravity has long been a preoccupation among Tibetan monks, yogis, UFOlogists and science fiction writers. On the other hand, Einstein's theory of relativity — the best available theoretical description of gravity — leaves little room for antigravity. This beautiful theory, however, is believed by many physicists to be only an approximation, the reason being that it is inconsistent with the twentieth century's most powerful physical idea — quantum mechanics.

Attempts to unite mathematically Einstein's gravity with quantum mechanics have been frustrated for decades by daunting technical and conceptual problems. Recently, though, a promising new approach has emerged. Known as supergravity, the new theory attempts to treat the familiar gravitational field as only a component part of a more elaborate network of forces and fields. It is within this wider network that hitherto unsuspected forces could arise to neutralise gravity.

Quantum mechanical theory is a set of principles that governs the subatomic world and supergravitators think of gravity in terms of subatomic particles. The ordinary force that keeps our feet on the ground is interpreted in this theory as due to a continual exchange of a hypothetical quantum particle called the graviton. The graviton is gravity's counterpart to the photon of electromagnetism. A crucial difference between gravitons and photons is that the former has twice as much spin as the latter, which can be shown to account for the fact that like electric charges repel, whereas like massive bodies attract. In units of photon spin, the graviton has spin 2.

0028-0836/80/08717-02$01.00

For comparison, the elusive neutrino has spin ½, as do electrons and protons, whereas pi-mesons have no spin. The amount of spin carried by a subatomic particle is crucial to the type of mathematics used to describe it. Particles like mesons, photons and gravitons, with integral units of spin, enjoy certain geometrical symmetries that are different for the half-integral spin particles. For many years physicists regarded these two categories of particle as quite distinct forms of matter and energy. Then, in the 1960s, when the variety of subatomic particle species grew bewilderingly fast, it was discovered that many particles hitherto regarded as different could, in a certain mathematical sense, be envisaged as simply different faces of the same basic unit. Physicists began to group the particles into families: the neutron and the proton, for example, became part of an octet of particles that can be thought of as eight slightly different manifestations of just one particle.

In the early schemes, the integral and half-integral spin particles were always kept in separate families because of their very different mathematical symmetries. But in the 1970s several people proposed arrangements in which even those two groups could be mixed together in still larger families, enjoying a new, all-embracing, 'supergravity'. It is from this development that supergravity has arisen. Early models of supergravity put the spin 2 graviton in a small family unit with a completely new particle — the more hypothetical gravitino — having spin 3/2. Soon this model was extended to a family with one spin 2 graviton, two spin 3/2 particles and a single spin 1 particle, like the photon. It is this latter entity that could be responsible for antigravity.

Writing in a recent issue of *Physics Letters* (**88B**, 265; 1979) J. Scherk of the Laboratoire Normale Superieure in Paris, examines the feasibility of the antigravity idea within the context of an extended supergravity model. Basing his analysis on earlier work by K. Zachos of Caltech (*Phys. Lett.* **76B**, 329; 1978), Scherk points out that circumstances could arise in which the spin 1 component of supergravity exactly neutralises the spin 2 gravity. At first sight, the theory seems to predict that the gravitational force between neutrons should be exactly neutralised by spin 1 antigravity. This would render the theory nonsensical — more than half the mass of the Earth is in the form of neutrons. However, the way in which gravity and antigravity affect the matter might be different. Closer examination shows that while ordinary gravity responds to the entire mass of a body, for example a whole neutron, antigravity sees only the elementary constituents. Particles such as neutrons and protons are believed to be composites of three so-called quarks.

Paradoxically, the assembly of three quarks does not have the same mass as three individual quarks. This is because enormous energies are released when the quarks bind together, and this energy also has mass. Taking this into account, Scherk estimates that the effects of antigravity would suppress the Earth's gravitational force on a body by about one part in a million, depending on the proportion of neutrons to protons in the substance concerned. This is well above the experimental upper limit obtained by comparing the rate of fall of differently constituted bodies.

To rescue antigravity from the problems of its own strength, Scherk speculates that although the antigraviton is described by the theory as massless, implying that it travels at the speed of light, it could acquire a small mass spontaneously as a result of a mechanism called symmetry breaking. The upshot of this idea is that the antigraviton is slowed up and the antiforce becomes short in range — perhaps extending for only a couple of metres. It is also greatly depleted in strength. Though this mechanism thereby renders antigravity utterly insignificant under most circumstances, Scherk remarks somewhat tongue-in-cheek that at a high enough temperature the symmetry breaking would fail, and antigravity could be important. The snag is, the temperature concerned would have to be well in excess of billions of degrees. So much for levitation! □

The closest cosmic radio source

from Alan Johnstone

VERY few of the radio sources discovered by radioastronomers will ever be visited by spacecraft carrying instruments capable of observing directly the electromagnetic fields and charged-particle distributions which generate the radio waves. Jupiter and Saturn are likely to be the only cosmic radio sources, observable from the ground, where *in situ* plasma measurements can be made. If some spacecraft were able to observe a celestial radio transmitter from within, the information would be extremely valuable, first because it would considerably improve the chances of understanding the source mechanism and second because the resulting knowledge could then be applied to more remote situations where there is no chance of *in situ* measurements.

Fortunately there is no need to send a spacecraft all the way to Jupiter to make these measurements; the closest such radio source is only a few thousand kilometres above the Earth's surface, where radio noise in the kilometric wavelength range (100 kHz — 1 MHz) is generated. Unlike most of the radio noise created in the Earth's magnetosphere it escapes outward from the source region into space because the frequency is above the local plasma frequency. It cannot be detected on the Earth's surface because the frequency is below the peak plasma frequency in the ionosphere, so that all the radiation which starts downward is reflected back out again. The power radiated from the Earth is extremely variable, averaging 10^7 W and reaching peaks in excess of 10^9 W, making it comparable with Jupiter as a radio source. At its maximum the radiated power is 1% of the rate at which energy is being dissipated in the atmosphere by precipitating electrons during an auroral display. This comparison is important because the radiation seems to come from the region where auroral electrons are accelerated and to occur only at times when there are active, discrete, auroral forms visible in the auroral oval.

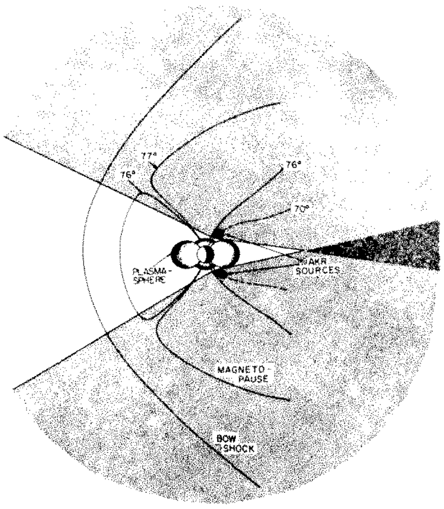

Fig. 1 The time-averaged extent of the conelike emission of auroral kilometric radiation superimposed on a magnetic field model. On the average both sources are observable in the equatorial plane on the nightside beyond 12 R_E (Gallagher & Gurnett *op. cit.*).

It is difficult to locate the source accurately from a spacecraft since an appropriate antenna consists typically of a single, long electric dipole which does not provide sufficient directional information. So far, two methods have been used. The first used the fact that the spin-modulation of the signal strength is a minimum when the antenna is pointed towards the source (Gurnett *J. geophys. Res* **79**, 4227; 1974). The minimum had an angular width of 6° when the source was observed looking back toward the Earth from a distance of 32 Earth radii (32 R_E). This placed the source close to Earth, but did not locate it precisely. The second method used the occultation of the source by the Moon as seen from a spacecraft in orbit around the

0028-0836/80/08718-02$01.00

Moon (Alexander & Kaiser *J. geophys. Res.* **81**, 5948; 1976). They found that the source is strongest and most common in the local time sector from 21 hours to 24 hours, the time at which auroral arcs are most common. From the Moon at first quarter the night-time magnetic field lines are seen in profile. The source of the auroral kilometric radiation then seems to lie along high-latitude field lines within a few R_E of the Earth's surface.

Gallagher and Gurnett (*J. geophys. Res.* **84**, 6501; 1979) have used a totally different approach. They collected data from two satellites for a total of 7 years and found the average intensity of the kilometic radiation as a function of radial distance, local time and magnetic latitude. Despite the variability of the source strength, they find that the average intensities are meaningful in tracing the source. The average intensity integrated over geocentric spherical shells (to find the total outward flux) is negligible below 2.5 R_E, rises to maximum at 4 R_E and then remains essentially level to 30R_E. This places the source between 1.5 R_E and 3 R_E above the surface. The radiation originates at auroral latitudes, between 22 and 24 h local time, spread out over a wide cone (Fig. 1). The average intensity decreases outwards from the source as $1/R^2$ if it is assumed to be at an altitude between 1 R_E and 2 R_E.

This is now known to be where auroral electrons are accelerated by several thousand volts, possibly by an electric field parallel to the magnetic lines of force. There can now be little doubt that the kilometric radiation is related either to the acceleration process itself or to the interaction between the beam-like electron velocity distributions and the cooler ionospheric plasma. Since the radiated power is as high as 1% of the energy of the accelerated electrons, the mechanism — whatever it is — must be a coherent and efficient process. There is no generally-accepted theoretical explanation and a great deal of effort is being expended to find one. There have only been a few *in situ* measurements in the region of interest, despite its relative accessibility, although the number should soon be increased by the NASA Dynamics Explorer Satellites. There should be advances on this scientific front before long.

It is clear that it would have been very difficult to have deduced the type of electron velocity distributions occurring in the source region from the characteristics of the radiated spectrum alone. This emphasises the importance of *in situ* measurements in unravelling the working of complex plasma processes. Many important and common plasma processes occur nearby in the magnetosphere where such measurements can be made easily. Auroral kilometric radiation is similar in spectral and temporal structure to the decametric radiation from Jupiter and the hectometric radiation from Saturn (Kaiser & Stone *Science* **189**, 285; 1975) so lessons learned in the magnetosphere can be applied to Jupiter and Saturn and then perhaps extended to more remote sources.

A new look at the Sherborne bone

from Ann Sieveking

In a recent number of *Antiquity*, (**53**, 211; 1979), R.A.H. Farrar has put forward a case for reconsidering the status of the Sherborne bone. This small engraving of a horse's head and forequarters was published by Arthur Smith Woodward in 1914, as apparently Palaeolithic in date but, 10 years later, was dismissed by Professor Sollas in the third edition of his book *Ancient Hunters and their Modern Representatives* as a forgery (see *Nature* **117**, 86, 233; 1926). The controversy continued in *Nature*, with Sollas emerging as the victor, although more by Smith Woodward's default than by the production of any conclusive proof. The question has been re-examined from time to time, at least with regard to the alleged evidence of hoaxers, or hoaxed, but little attention has been given to the bone itself, except for an analysis of its degree of fossilisation, made by K. Oakley in 1957. Some of the protagonists in fact, apparently including Sollas himself, never looked at the original.

There is little evidence to support a renewed claim for authenticity however. Such evidence as we have about the discovery of this engraved bone is hearsay, contradictory and unacceptable; its provenance, whether it was found in a heap of quarry stones, or in a rubbish heap beside the Bristol road, is without context and its intrinsic characteristics lend little credibility to a Palaeolithic attribution. At this stage the only useful contribution one may make to the problem is in examining the bone itself and here it must be emphasised that it is not the antiquity of the bone that is in question, (Oakley's analysis confirmed it as being fossilised) but the age of the engraving on it.

Smith Woodward maintained that the surface of fossilised bone would flake when engraved and that the Sherborne horse, cut with a relatively clean line, must therefore have been engraved when the bone was fresh. However, tests made by M.H. Newcomer at the Institute of Archaeology do not support this claim: as clear a line may be cut with a flint burin on fossilised bone as on fresh. Further analysis of the technicalities of the engraving (for which observations I am grateful to Dr Newcomer) demonstrates that the surface of the Sherborne bone shows no preparation before engraving, although this is a common feature on Palaeolithic pieces. Under magnification it can be seen that, at certain points, where the engraved line crosses a natural crack in the bone, the cut dips down into such a crack whereas a line engraved before any cracking occurred would maintain an even depth. In addition, the engraved lines of the head are discontinous and hesitant which, although in no way conclusive is, again, uncharacteristic of Palaeolithic work. Lastly, in the region of the mane of the Sherborne horse, the original surface of the bone has flaked away in antiquity, leaving a rougher surface below. The engraved lines of the mane, however, start on the smooth original surface of the bone and continue onto the rougher flaked surface (See Figs 1 and 2) at the edge. Had the engraving been contemporary with the fresh bone, these lines could be expected to have been truncated by the flaking, and the fact that they are not suggests that the engraving has been added subsequently to an already degraded bone.

Finally the stylistic characteristics of the Sherborne engraving must be considered. Farrar remarks that the Sherborne horse has an upstanding mane and lacks clearly defined ears, both of which characteristics may be paralleled in Palaeolithic examples, for instance in the Creswell Crags engraving (in the British Museum collections) and that less characteristically the Sherborne horse shows no linear definition below the mane and has an unusually drooping muzzle. He cites a parallel to this atypical muzzle in an illustration in Graziosi (*Palaeolithic Art*, 1960; Pl. 134.b); this illustration, however, is a drawing and not a photograph of the original engraving in the cave of Pindal and in this respect of the drooping muzzle it is inaccurate. The engravings of horse heads from La Grande Paroisse, Pincevent and from Cépoy in Loiret, which are closer than is Pindal in date, location and the form of support used to the English Upper Palaeolithic art pieces, show an animal with a short, broad

Fig. 1 The Sherborne bone (actual size ~8.5 cm), now in the collections of the British Museum (Natural History). Photo: Jill Cook.

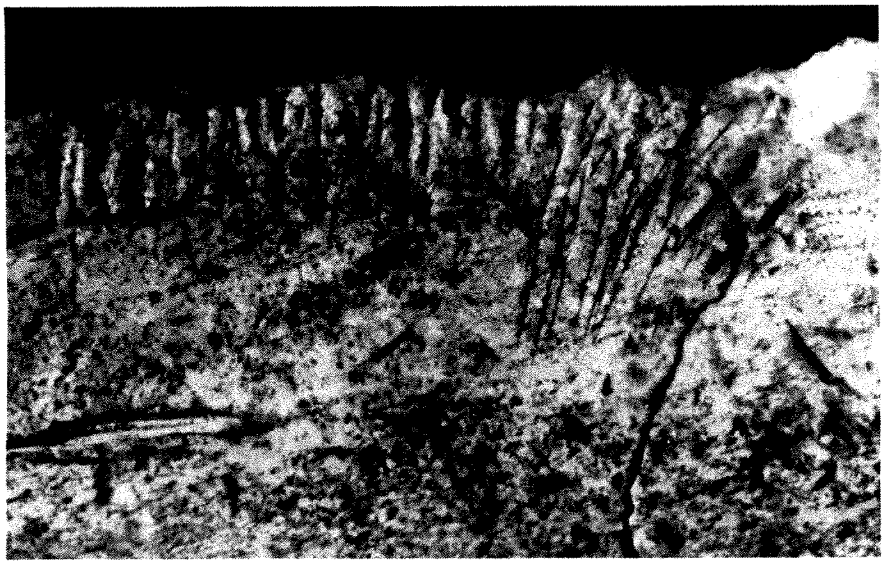

Fig. 2 Enlargement of the mane of the Sherborne horse. Photo: Jill Cook.

head that is very similar to that engraved on the Creswell Crags bone and rather dissimilar to the Sherborne variant. Sollas suggested that the illustration of the Creswell Crags horse, published (for the second time) by Boyd Dawkins in 1880, was the inspiration for the Sherborne piece, in that both show head and forequarters of a horse, facing right, with an upstanding mane. There seems some force in this argument, for the Sherborne horse is much more similar to Boyd Dawkins' rather poor illustration than to the original Creswell piece. Side by side the Sherborne and Creswell originals have little in common, the Creswell horse, for example is extremely delicately engraved, but this is not a characteristic that is conveyed in the illustrations and it is not a characteristic repeated in the Sherborne engraving. Furthermore, if the Sherborne copyist had seen the original Creswell engraving he might have appreciated the importance of the numerous additional odd lines that occur on the surface of this bone. Some of these appear in Boyd Dawkins' illustration, but might here well be dismissed as cracks, although they are a very consistent feature of Palaeolithic decoration. It is unusual to find a Palaeolithic engraving that is devoid, as is the Sherborne horse, of any extraneous lines, though these are not always included in illustrations of the material. Obviously there is no way of conclusively determining the age of an engraving as opposed to the age of its bone support, but such evidence as can be cited suggests that the Sherbone horse is not an authentic Palaeolithic engraving. The catalogue of Palaeolithic art pieces from this country is very small but to augment it by including the Sherborne horse appears to be quite unjustifiable. □

Ann Sieveking researches into Palaeolithic Art at the Institute of Archaeology, London.

Geology and health

from a Correspondent

THE influence of minerals and chemicals naturally occurring in the environment on health, together with the problems that arise in the mining and industrial use of minerals were reviewed at a recent meeting in London*. P. C. Elmes and J. C. Wagner (MRC Pneumoconiosis Unit) reviewed the diseases resulting from occupational and environmental exposure to mineral dusts. On the one hand are those which lead to lung scarring and malfunction such as silicosis, coal miners' pneumoconiosis and asbestosis, in which the severity of the symptoms is directly related to the intensity and length of exposure, and on the other are the more insidious cancers, where exposure may be small and the time lag to distress and diagnosis as much as 30–40 years. The load of dust in the lung associated with disease varies widely, from several hundred grams of coal dust, 5-10 g of pure silica to as little as 1 mg of asbestos. Both asbestos exposure and smoking increase the risk of lung cancer, but combining the two multiplies the risk. A recent discovery of an extremely high prevalence of the rare pleural mesothelioma in the village of Karain, in Cappadocia, Turkey, where in one year all 11 deaths out of 800 inhabitants were due to this one disease (there were no cases in the surrounding villages), has been linked with the presence of a zeolite mineral, erionite, which is found in the volcanic tuff rock from which local houses are built, and which weathers to form the soil on which this agricultural community depends. Similar fibrous minerals of 0.01–0.5 μm in diameter and 5–15 μm in length, a dimension that is retained in the body tissues and causes cell damage, occur in other geological materials and must be a cause of concern.

The large-scale development of natural resources to meet the energy crisis will have important environmental consequences. W. Chappell (Center for Environmental Sciences, University of Colorado) forecast the production of 1 million barrels of oil a day from oil shale in the US by the late 1990s, requiring the processing of 500 million tons of shale per annum, as much as the present-day coal production in the US. Problems of waste disposal, release of toxic trace elements and organics into surface and ground waters and emissions of SO_2 into the atmosphere will expose workers and local communities to possible health hazards. Projected large scale expansion in surface coal mining over the next five years has led to studies linking epidemiology and water quality in the Midwestern USA, a programme funded by the Environmental Protection Agency and undertaken by Betsy Kagey (Downstate Medical Center, New York) and B.G. Wixson and N.L. Gale of the Environmental Research Center, University of Missouri — Rolla.

Geochemical investigations linking heavy metals in soils and the prevalence of dental caries were described by B.E. Davies (University of Wales, Aberystwyth) and R.J. Anderson (Dental School, University of Birmingham). Caries incidence has been found to be above normal where soils are heavily contaminated with lead from old metalliferous mining and smelting activities.

The Applied Geochemistry Research Group at Imperial College and the Institute of Geological Sciences have over the years mapped most of the country and geochemical atlases of England and Wales, Northern Ireland and parts of Scotland have been published. Research initiated by John Webb in the early 1960s has shown that regional geochemical differences can be successfully related to the health of crops and livestock, and that maps have uses in agriculture, water resources, pollution studies and public health. The Atlases will continue to provide unique sources of data on many different elements which can aid in selecting areas for food, water and medical surveys, particularly in rural parts of the country.

J. Lag (University of Oslo) reported that the Academies of Science in the five Scandinavian countries are setting up a committee to organise further cooperation in geomedical investigations. This will in part fulfil a similar role to the Working Party on Environmental Geochemistry and Health in Britain established in 1979 by the Royal Society under the chairmanship of S.H.U. Bowie. Consultation and cooperation in this expanding multidisciplinary research area should now be possible between scientists in the UK, Scandinavia, USA, Canada, USSR and Australia which now all have similar groups of interested scientists. □

*A one-day discussion meeting on Geology and Health was held on 30 January at the Geological Society of London, Burlington House, and organised by Dr Iain Thornton, Imperial College.

Nature Vol. 283 21 February 1980

REVIEW ARTICLE

A list of interstellar molecules

A. P. C. Mann & D. A. Williams
Mathematics Department, UMIST, Manchester M60 1QD, UK

Interstellar molecules are useful guides to the conditions within interstellar clouds. The list presented here gives information on the sources, abundances and conditions of all interstellar molecules identified up until September 1979.

THE number of molecules identified in the interstellar medium has increased dramatically during the past decade: Fig. 1 shows the number discovered per year. As well as being of intrinsic interest, the molecules are useful tracers of the interstellar gas, and they can inform us of conditions within the interstellar clouds. The wide chemical variety present interesting problems of formation.

We present in Table 1 a list of interstellar molecules presently (September 1979) identified, and some information pertaining to them. The information selected is that likely to be of interest to a general reader and to those interested in the physics and chemistry of interstellar clouds, rather than in making observations. The first discovery is noted, and survey references are given, with some information regarding sources, abundances and conditions. An excellent compilation of radio and microwave frequencies of observed interstellar molecular transitions has been prepared by Lovas, Snyder and Johnson[1]. We do not attempt to duplicate that information here.

For convenience, we have attempted to make Table 1 as concise as possible and have not included all lines observed for each molecule. In general, the information for each molecule is usually given on two lines of the table: the information on each line is from the reference on that line. The first line is devoted to the discovery reference, the second to a survey reference, if available. (Some particularly important molecules—H_2, OH and CO—are given extra space.) A description of Table 1 now follows; the molecules are arranged by number of atoms they contain, and then by molecular weight.

Column 1

Chemical formula, and name: the main isotopic version is given first; minor isotopes follow, in order of atomic weight. Atoms not identified by an isotropic weight are the predominant isotope: that is, C implies ^{12}C.

Column 2

References: the first reference given is that of the first observation; the information on the same line in Table 1 refers to this reference. On the second line of information for the same molecule, another reference is given, where possible. This is a reference to a survey, if available.

Column 3

Sources. On the first line are given the sources in which molecule was first observed; on the second line the number of sources in the survey reference, or main sources in the second reference.

Column 4

Spectral line: this contains some information about the spectral lines observed. Ultraviolet (UV), optical (OPT), and infrared electronic (IR) transitions are indicated. Otherwise, the lines are in the microwave or radio spectral regions. The type of transition is briefly indicated; electronic bands defined; 'Rot' implies a rotational transition; Λ implies that Λ-doubling is observed; and 'Hfs' implies that hyperfine structure is detected in the observations.

Column 5

Spectrum: absorption (A), emission (E), or maser emission (M) is indicated.

Column 6

Column density: the number given is the column density, per cm^2, calculated by the authors of the work referenced, under the assumptions listed in **column** 7. If column densities are not available, other relevant information, such as abundance ratios, may be given.

Column 7

Conditions: assumed (or inferred). Assumed information may involve the total gas number density n, per cm^3, and temperature (such as rotation, spin, excitation, and kinetic) in degrees Kelvin. The type of calculation used by the authors is also mentioned. Inferred information about the source, if given, is in brackets.

Column 8

Comment: any useful remark is given here.

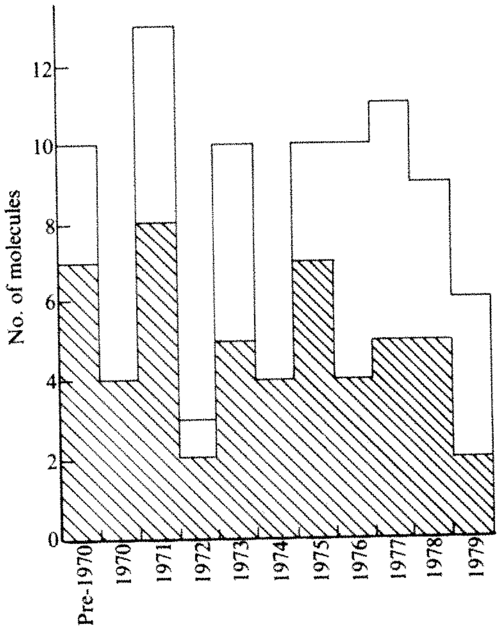

Fig. 1 Rate of discovery of interstellar molecules in recent years. Hatched totals ignore isotopic varieties.

DCO^+	86	3 sources	1–0, Rot	*E*	$[H^{13}CO^+] \sim [DCO^+]$	opt. thin	High $[DCO^+]/[HCO^+]$ implies $X(e) < 10^{-8}$ in dense clouds
	87	8 sources					
$H^{13}CO^+$	85	10 sources	1–0, Rot	*E*	$\lesssim 0.1[HCO^+]$	opt. thin	Confirms HCO^+ detection See also ref. 86
	—						
$HC^{18}O^+$	89	L134, TMC1	1–0, Rot	*E*		opt. thin	$[H^{13}CO^+]/[HC^{18}O^+] \sim 6$
	90	Sgr B2	1–0, Rot	*E*		opt. thin	~terrestrial isotope ratios
HCO	91	4 sources	$1_{01}–0_{00}$, $J = \frac{3}{2} – \frac{1}{2}$, $F = 2–1$	*E*	$\sim 10^{13}$	$T = 20$	$[HCO] < [HCO^+]$
Formyl	—						
N_2H^+	92	11 sources	1–0, Rot, Hfs	*E*	$\sim 3 \times 10^{13}$	$T_s = 10$	ref. 93: calculation, and ref. 94: lab. spectrum
	—						
N_2D^+	95	L134N	1–0, Rot, Hfs	*E*	$\sim 10^{12}$	opt. thin. $T_K \approx 15$	$N_2H^+/N_2D^+ \approx 2$. Enormous isotope fractionation
	—						
H_2S	96	7 sources	$1_{10}–1_{01}$ Rot	*E*	$\lesssim 10^{15}$	opt. thin $T = 20$	
Hydrogen sulphide	—						
HNO	97	Sgr B2, NGC2024	$1_{01}–0_{00}$, Rot	*E*	$\lesssim 10^{15}$	opt. thin	$N \lesssim 10^{14}$ (NGC2024)
Nitroxyl	—				(Sgr B2)	Boltzmann $T < 100$	tentative?
OCS	98	Sgr B2	9–8 Rot	*E*	$\lesssim 3 \times 10^{15}$	opt. thin	
Carbonyl sulphide	99		Several, Rot	*E*		Boltzmann $T < 50$	See also ref. 100
SO_2	101	Ori A, Sgr B2	Several, Rot	*E*	$\sim 10^{16}$	opt. thin	Narrow (interstellar?) and broad (circumstellar?) components seen
Sulphur dioxide	—					Boltzmann $T \approx 100$	
4-atomics							
NH_3	102	Sgr A	(1,1)(2,2) inversion	*E*	$\sim 2 \times 10^{16}$	opt. thin	Seen in many dense clouds, possibly 'clumpy'?
Ammonia	106	11 sources	(1,1) (2,2) inversion	*E*			
NH_2D	103	Sgr B2	$1_{11}–1_{01}$, Rot	*E*	$\sim 10^{14}$	$n \sim 10^6$, opt. thin	$[NH_2D]/[NH_3] \sim 0.017$
	104	Orion, KL	$1_{11}–1_{01}$, Rot	*E*	$\sim 10^{14}$	$50 \lesssim T_K \leqslant 150$	
$^{15}NH_3$	105	Orion	(1,1)(2,2)(3,3)	*E*	a	opt. thin $T_R \sim 50$	*a*, $[^{14}N]/[^{15}N] \approx$ terrestrial
	—						
C_2H_2	107	IRC+10216	Several, Rot	*A*	$\lesssim 10^{17}$	LTE $T = 300$	Circumstellar source, not 'genuine' interstellar
Acetylene	—						
H_2CO	108	17 sources	$1_{11}–1_{10}$, Rot	*A*	$\sim 10^{14}$(Sgr A)	a	a, $1_{10}–1_{10}$ is seen in absorption against 2.7 K BB
Formaldehyde	110	28 sources		*A*			
HDCO	109	L134N, CLD2	$2_{02}–1_{01}$, Rot	*E*	a	$T_{Kin} = 10$	$[HDCO]/[H_2CO?] \lesssim 0.1$ D enhanced
	—	—					
$H_2{}^{13}CO$	111	Sgr A, B2, W51	$1_{11}–1_{10}$, Rot	*A*	a	opt. thin	a, $[H_2CO]/[H_2{}^{13}CO] \sim 10$ in galactic centre. W51 tentative
	112	Sgr B2					
$H_2C^{18}O$	113	Sgr B2	$1_{11}–1_{10}$, Rot	*A*	$(^{13}C:{}^{12}C)/(^{18}O:{}^{16}O) \approx 10$	opt. thin	Using ref. 111
	114	Sgr A, B2, W33	$1_{11}–1_{10}$, Rot	*A*	b	opt. thin	b, $[H_2{}^{13}CO]/[H_2C^{18}O] \approx 7$
HNCO	116	Sgr B2, W51	$4_{04}–3_{03}$, Rot	*E*	$\sim 5 \times 10^{14}$	opt. thin	Also $1_{01}–0_{00}$ detected, ref. 115
Isocyanic acid	—						First report ref. 75
H_2CS	117	Sgr B2	$2_{12}–2_{14}$, Rot	*E*	$> 10^{16}$	opt. thin	See also ref. 59
Thioformaldehyde	118	Sgr B2	$4_{14}–4_{13}$, Rot	*A*	?		Non thermal
C_3N	119	IRC+10216	10–9–8, Rot	*E*	$\lesssim 10^{15}$		Based on calculated spectrum, ref. 120
Cyanoethynyl	—						
HNCS	163	Sgr B2	Rot, 3 lines	*E*	$\sim 2 \times 10^{13}$	$T_R = 14 \pm 5$, opt. thin	
Isothiocyanic acid		—					
	—	—					
5-atomics							
CH_4	122	Ori A	6 lines, Rot	*E*	$\sim 10^{22}$(?)	Non thermal excitation	Column density uncertain
Methane	—						Tentative identification
CH_2NH	123	Sgr B2	$1_{11}–1_{10}$ (Mult) Rot	*E*	$> 3 \times 10^{14}$	opt. thin. $T_x \gg 25$	
Methanimine	—						
CH_2CO	124	Sgr B2	Several, Rot	*E*	10^{14}	Stat. eqm.	Tentative identification of 3 more Rot. lines
Ketene	—					$n > 10^6$, $T_k \gtrsim 20$	
NH_2CN	125	Sgr B2	$4_{13}–3_{12}$, $5_{14}–4_{13}$, Rot	*E*	2×10^{13}	Stat. eqm.	
Cyanamide	—				-6×10^{14}	$n \lesssim 10^6$, $T_k \lesssim 60$	
HCOOH	126	Sgr B2	$1_{11}–1_{10}$, Rot	*E*	$10^{12}–10^{13}$		Tentative? See ref. 5
Formic acid	127	Sgr B2	$2_{11}–2_{12}$, Rot	*E*	$\sim 5 \times 10^{13}$	$T_R \approx 2.2$	
C_4H	128	IRC+10216	12–11–10–9–8, Rot	*E*	$4 \times 10^{14}–3 \times 10^{15}$	$60 < T_{ex} < 600$	Detection based on theoretical calculation of rotational spectrum
Butadiynyl	—						
HC_3N	129	Sgr B2	0–1 Rot	*E*	a: $\sim 10^{14}$	opt. thin. $T = 50$	a, corrected, see ref. 130
Cyanoacetylene	131	17 sources	7 transitions	*E*	$> 10^{14}$	Stat. eqm.	See ref. 131 for other refs
$H^{13}CCCN$	132	Sgr B2	1–0, Rot	*E*	$\sim 0.05[HC_3N]$	opt. thin	
	133	Sgr B2, Ori A	9–8 Rot	*E*			$^{12}C/^{13}C = 22$(Sgr B2), 50(Ori A)
$HC^{13}CCN$	134	Sgr B2	0–1 Rot	*E*			
	133	Sgr B2, Ori A	9–8 Rot	*E*			
$HCC^{13}CN$	134	Sgr B2	0–1 Rot	*E*			
	133	Sgr B2, Ori A	9–8 Rot	*E*			
6-atomics							
CH_3OH	135	SgrA, B2	$1_{10}–1_{11}$ Rot	*E*		opt. thin	Column densities higher towards Sgr and KL nebula
Methyl alcohol	136	14 sources	2–1, several, Rot	*E*	$\sim 6 \times 10^{14}$	Stat eqm.	Other transitions ref. 88
$^{13}CH_3OH$	136	Sgr B2	2–1, several, Rot	*E*		Stat. eqm.	$[^{13}CH_3OH]/[CH_3OH] \approx 0.1$
CH_3OD	136	Sgr B2	2–1, several, Rot	*E*		Stat. eqm.	$[CH_3OD]/[^{13}CH_3OH] \approx 0.1$
CH_3CN	137	Sgr A, B2	6–5 Rot	*E*	2×10^{14}	Stat. eqm.	
Methyl cyanide	138	Ori A	5–4 Rot	*E*		$n > 10^6$, $T > 150$	
NH_2CHO	139	Sgr A, B2	$2_{11}–2_{12}$ Rot, Hfs	*E*	6×10^{14}	Stat. Eqm	
Formamide	140	Sgr A, B2	$1_{11}–1_{10}$, Rot, Hfs	*E*	$\sim 10^{15}$	$T = 100$, $n = 10^5$	
CH_3SH	121	Sgr B2	Rot, 6 lines	*E*	$\sim 10^{14}$	$T_R = 9 \pm 3$, opt. thin

Cyanotriaceylene (or cyanohexatriyne)	159	TMC 1, 2	22–21, Rot	*E*	$\sim 2 \times 10^{12}$		
11-atomics							
HC_9N	160	Heiles 2	18–17, 25–24, Rot	*E*	$\sim 3 \times 10^{12}$	opt. thin $T = 11$, $n = 4 \times 10^4$ Coll. Ex.	Rot. spectrum extrapolated from cyanopolyene series
Cyano-octatetra-yne							

Discussion

We have occasionally indicated that a detection may be only tentative. Factors tending to confirm the presence of a molecule are: (1) the existence of several spectral lines, all showing the same velocity shift; (2) detection in a number of astronomical sources; (3) the identification of an isotopic version of the molecule at the corresponding frequencies; and (4) hyperfine structure at the correct splitting. Thus, for example, HCO^+ observed in but a single line, is confirmed not only by the laboratory spectrum, but also by the isotopic versions $H^{13}CO^+$ and DCO^+, at the correct frequencies, in the same astronomical sources.

Some ambiguity occurs: when is a molecule circumstellar, and when interstellar? Clearly no nice division occurs, and we have not attempted to make one. The source Sgr B2 towards the galactic centre remains the richest, but there are some surprises here; it does not exhibit (as yet) the three most massive molecules known. Isotopic ratios are important indicators of interstellar chemistry, and, again, the galactic centre seems to be an anomalous region in this respect. Fractionation of isotopes is apparently very effective; certain isotopic versions may be overabundant by orders of magnitude.

Of these 90 molecules, the chemistry of, perhaps, 10 is thought to be understood, though theoretical models are often in conflict with observation. The list is a reminder of the complexity of the problems awaiting solution. The interested reader will find the astrophysical context well reviewed in refs 2–5.

We thank Drs D. McNally, T. J. Millar, L. Snyder, and W. B. Somerville for helpful advice. A.P.C.M. is supported by an SRC Studentship.

Interstellar extinction in the Large Magellanic Cloud

K. Nandy*, D. H. Morgan*, A. J. Willis†, R. Wilson†, P. M. Gondhalekar‡ & L. Houziaux§

* Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ, UK; † Department of Physics and Astronomy, University College, London, Gower Street, London WC1E 6BT, UK; ‡ SRC Appleton Laboratory, Ditton Park, Slough, Buckinghamshire, UK; § Institut d'Astrophysique, Université de Liège, Belgium

Recent UV observations together with complementary visible data of several reddened and comparison stars of similar spectral types in the Large Magellanic Cloud have been used to study the interstellar extinction in that galaxy. Most of the reddened stars studied here are located within 2° of 30 Doradus and show remarkably high extinction in the far UV, suggesting a large abundance of small particles. From the optical wavelength to 2,600 Å *the normalised extinction curves of the LMC stars are similar to the mean galactic extinction law.*

THE Large Magellanic Cloud (LMC) is the nearest extragalactic system and a preliminary study of the UV spectra of LMC members shows the importance of the IUE[1] for stellar and interstellar work in the Magellanic Clouds. The Clouds contain dust though to a lesser extent than the Galaxy. A recent survey of the chemical composition of H II regions in the Magellanic Clouds[2] reveals that oxygen is deficient in these galaxies by about a factor of four relative to the Orion nebula. The composition of the interstellar dust and gas in the Clouds provides important information on the origin of the dust and the chemical enrichment of the interstellar media in these galaxies.

The wavelength dependence of interstellar extinction over a wide range of wavelengths from the visible to the UV depends on the composition and relative abundances of the agents responsible for scattering and absorption[3]. The characteristic feature of the galactic extinction curve is the broad symmetric absorption band ($\Delta\lambda \sim 750$ Å) centred near 2,200 Å (ref. 4). Earlier attempts to determine the UV extinction law in the LMC, using surface brightness measurements obtained with the

S2/68 (ref. 5) and ANS experiments[6,7] have led to discrepant results. The detection of the 2,200 Å feature in the spectrum of a reddened LMC member, SK-69-108, has recently been reported[8]. This article presents further observations, in both the visible and the UV, of a larger sample of LMC stars to study interstellar extinction in the LMC.

Observations

The IUE[9,10] controlled from the ESA satellite tracking station at Villafranca, Spain, was used in its low resolution mode ($\Delta\lambda \sim 6$ Å) to obtain UV spectra of the reddened and comparison stars. Complementary visible spectra which extend from 3,980 to 6,140 Å were obtained at a dispersion of 110 Å mm^{-1} using the image dissector scanner at the Cassegrain focus of the 3.6 m telescope of the ESO at La Silla, Chile. Table 1 lists the reddened and comparison stars observed, together with their coordinates, photometric data and spectral types[11–13].

The reduced UV spectra provided before August 1979 by the IUE ESA Observatory contained ITF errors in the short wavelength channel. Consequently, the photometric correction of the raw images of these spectra was repeated with the correct intensity transfer functions (ITF) using a program developed by J. Fettle (personal communication), and the corrected spectra extracted. The UV spectra in the long wavelength channel were provided by the ESA Observatory. Absolute fluxes were obtained using the adopted sensitivity calibration curve[14].

The wavelength scales were checked by examining the positions of the principal interstellar lines: 1,260 Å (blend of Si II and S II), 1,303 Å (O I, Si II), 1,335 Å (C II), 2,342 Å (Fe II), 2,382 Å (Fe II), 2,598 Å (Fe II) and 2,798 Å (Mg II). The wavelength scales of the reduced spectra were found in all cases to be accurate to ±4 Å. The raw images were checked for fiducial marks, noise, spikes and saturation effects. Data affected by saturation and fiducial marks were excluded. Except for the short wavelength spectrum of SK-69-213, all spectra were well exposed with average signal over all spectral ranges of interest lying over 100 DN (IUE data number). The UV flux distributions in absolute units smoothed over 10 Å bands of the comparison and reddened stars are shown in Fig. 1*a–c*.

The visible spectra were obtained on one night (25 December 1978). The wavelength and flat field calibration of the data, recorded on magnetic tape, was performed at ESO, Geneva, using He–Ar and flat field spectra taken immediately before the stellar observations. As the difference between the air masses at the beginning and the end of the observing night was small, the visible spectra were corrected for atmospheric extinction using the mean law appropriate for La Silla (by Dr H. Pederson of the ESO). The visible spectra were reduced to give data points every 1.5 Å and in the subsequent analysis average counts in 60 Å wavelength intervals from $\lambda^{-1} = 1.66$ to $2.54\ \mu\text{m}^{-1}$ were utilised. The photometric accuracy of the average counts is $\sim\pm3\%$.

Measurement of interstellar extinction

The analysis of the spectral features in the UV and visible data obtained will be given elsewhere. Note, however, that the reddened stars listed in Table 1 clearly show the diffuse interstellar feature at 4,430 Å similar to that observed in reddened stars in the galaxy. The equivalent width of this feature is compatible with that computed from the colour-excess, $E(B-V)$, from the mean galactic relationship between W_{4430} and $E(B-V)$ (ref. 15).

To measure the extinction in the visible wavelength range, a set of extinction curves was derived for each of the reddened stars using comparison stars, and a mean extinction curve was determined for each reddened star, thus reducing the errors introduced by possible spectral type mismatch. The extinction in magnitudes, $\Delta m(\lambda)$ has been normalised to $\Delta m = 0$ at 5,500 Å (the effective wavelength of the V-band) and $\Delta m = 1$ at 4,300 Å (the effective wavelength of the B-band). Within observational errors, the individual extinction curves in the visible agree well thereby allowing a mean extinction curve to be constructed. The mean curve was computed in the wavelength range, $\lambda^{-1} = 1.66$–$2.94\ \mu\text{m}^{-1}$ with r.m.s. error $<\pm0.3$ mag, and extended to the U-band using the available UBV photometric data. This mean curve seems to be identical to the mean galactic extinction law in the visible as derived by Seaton[16].

For the measurement of interstellar extinction in the UV, the comparison stars SK-67-108 and SK-67-111, which were observed with the small (3×3 arc s) IUE spectrograph slits, were excluded. To improve the photometric accuracy of the UV data, the stellar fluxes were averaged in 50 Å bands from 1,150 to 3,000 Å. The mean photometric accuracy of a single observation has been estimated from the difference in the colours $(m_\lambda - m_{2{,}900\text{Å}})$ of stars with more than one observation: it is $\sim\pm0.05$ mag except near the extremities of the wavelength channels where it is much larger, about ±0.3 mag.

The UV extinction has been measured for pairs of reddened and comparison stars which match in spectral type. The extinction, Δm is normalised to $\Delta V = 0$ and $\Delta E(B-V) = 1$, where ΔV is the difference in the V magnitudes and $\Delta E(B-V)$ is the difference in the colour-excesses of the reddened and comparison stars. The UV extinction curves for eight reddened stars are shown in Fig. 2; the ordinate is the normalised extinction,

$$\Delta m = \frac{A_\lambda - A_V}{E(B-V)}$$

Discussion

Apart from photometric errors, the major source of error in the extinction measurements constructed from the pairs of reddened and comparison stars is the mismatch in spectral type and luminosity class. For the sample of LMC stars studied here, the spectral type error is estimated to be $\sim\pm1$ subclass. This estimate is based on an examination of the important spectral features both in the visible and in the UV. However, the difference in absolute magnitude, ΔM_V between the reddened and comparison stars is ~-1.6 mag. Galactic supergiants have a flux deficiency in the far UV (shortward of 1,600 Å) as compared with giants and dwarfs[17]. However, from a study of the spectra of galactic stars which appear in the Ultraviolet Bright-Star Catalogue[18] it is found that the UV flux distributions of B0-B3Ia stars do not differ significantly from those of B0-B3Ib stars, the differences being well within the photometric errors. The error in the measured extinction due to spectral type mismatch of ±1 subclasses per unit normalising factor is $\sim\pm0.2$ mag near 2,740 Å increasing to $\sim\pm0.4$ mag at 1,400 Å.

The interesting feature of Fig. 2 is that shortward of $\lambda^{-1} = 3.8\ \mu\text{m}^{-1}$ the extinction curve for SK-69-108 is clearly different from those of the other stars: shortward of $5.5\ \mu\text{m}^{-1}$ the extinction for SK-69-108 is on average 2 mag lower than that for the other stars and near 2,200 Å ($4.6\ \mu\text{m}^{-1}$) it is ~1 mag greater. But longward of 2,600 Å ($\lambda^{-1} = 3.8\ \mu\text{m}^{-1}$), the normalised extinction values for all the stars are the same. Note that the reddened star SK-69-108 is situated in the bar, while the other reddened stars are located to the north-east of the bar within 2° of the 30 Doradus region, a site of recent star formation. This raises the interesting possibility that the extinction properties of the dust in the latter region may differ from those of the dust in

* IUE observations recorded using the small spectrograph aperture. All other IUE data were obtained using the large aperture. Figure in brackets is photographic V-mag (ref. 11).

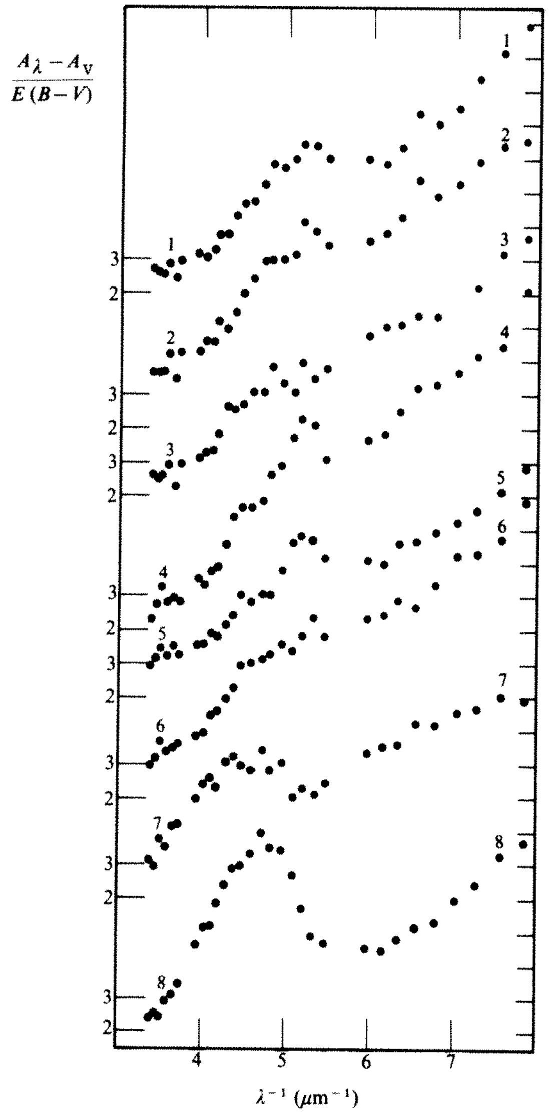

Fig. 2 Individual extinction curves normalised to $V = 0$ and $E(B-V) = 1$ derived from IUE observations. The numbers 1–8 denote the following pairs of reddened and comparison stars: 1, SK-68-107, SK-70-32; 2, SK-69-253, SK-70-32; 3, SK-68-135, SK-70-32; 4, SK-69-274, SK-68-177 and SK-71-17; 5, SK-70-116, SK-68-177; 6, SK-69-213, SK-65-9; 7, SK-69-274, SK-65-11; 8, SK-69-108, SK-71-17.

the bar. As the extinction curves of seven of the stars have similar shapes, they have been combined to give a mean curve. This curve is shown in Fig. 3 with the extinction curve for SK-69-108; also shown in Fig. 3 are the mean visible extinction curve as determined for the LMC stars, and for comparison the galactic extinction law of Seaton[16]. The mean normalising factor being 4, the r.m.s. error bar shown in the mean extinction curve can be explained in terms of the observational errors. Within this error, the extinction curve for SK-69-108 is close to the galactic law, while the mean extinction curve for other stars shows an increase in extinction by ~3 mag in the far UV shortward of $\lambda^{-1} = 6\ \mu\mathrm{m}^{-1}$, which is much larger than twice the r.m.s. error.

The 2,200 Å feature for the mean curve seems to be weaker than that for the galactic law, but not as much as suggested by Koornneef[7]. For example, the colour-excess ratio $E(2{,}200-2{,}500)/E(B-V)$ has a mean value of 2 for the seven stars, (2.7 for SK-69-108) and 2.5 for galactic stars. Between 4.6 and 5.5 $\mu\mathrm{m}^{-1}$ the mean extinction curve does not decrease as much as it does in the case of SK-69-108 and in the galactic law. This is partly due to the broad 1,920 Å feature ($\Delta\lambda \sim 100$ Å) of stellar origin, being much stronger in the spectra of five of the seven reddened stars than in the comparison stars. This 1,920 Å feature is due to a blend of Fe III lines, first detected in the S2/68 spectra of luminous stars and found to be independent of spectral type[19]. The structure near $\lambda^{-1} = 5.2\ \mu\mathrm{m}^{-1}$ in the mean extinction curve is due to this stellar feature. But when corrected by using interpolated continua for the 1,920 Å feature, the extinction near 1,920 Å decreased by only a few tenths of a magnitude. Therefore the difference between the mean extinction curve for the seven stars and the galactic law as well as SK-69-108 seems to be real shortward of 2,200 Å. A possible explanation for the increasing extinction in the far UV for the LMC region around 30 Doradus is that the relative abundance of small (a few hundred ångströms sized) dielectric particles is significantly greater than that in the interstellar medium in the solar neighbourhood.

The difference between the extinction curves for SK-69-108, located in the bar, and the other seven stars may indicate a regional difference in the extinction law in the LMC. Clearly further observations of reddened stars in the LMC bar are needed.

Conclusion

From the study of seven reddened stars located within 2° of 30 Doradus in a region to the north-east of the bar of the LMC, and five comparison stars, the mean extinction curve for this region shortward of 1,600 Å, shows significantly greater extinction than the mean galactic extinction law. This may be due to a relatively higher abundance of small (few hundred ångströms sized) dielectric particles. However, an eighth reddened star, SK-69-108, shows an UV extinction curve similar to the mean galactic law: but this star is located in the bar of the LMC, suggesting a possible regional variation of the far UV extinction law throughout the LMC.

The interstellar extinction curves of all the stars in the visible and near UV wavelength ranges show no significant differences from the mean galactic extinction law.

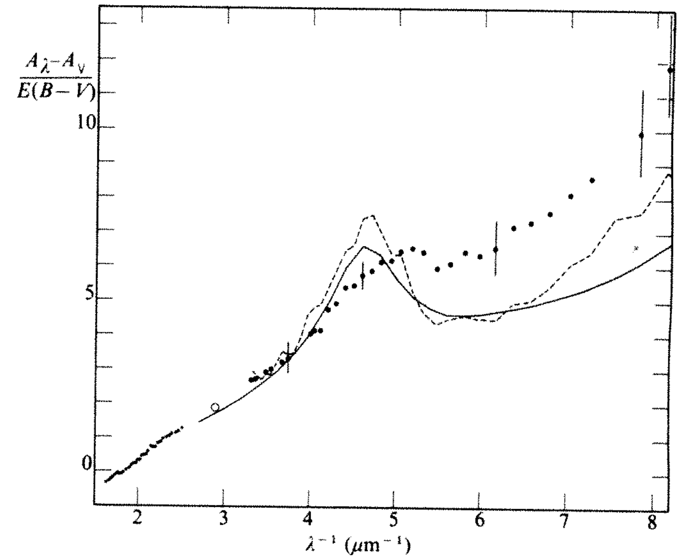

Fig. 3 The mean extinction curve derived from IDS data (dotted line); the mean extinction in the U-band (○); and the mean UV extinction curve for seven stars situated in a region within 2° of 30 Doradus (●). The dashed lines denote the extinction curve for SK-69-108 (situated in the bar). The solid line is the mean interstellar extinction law for the galaxy.

An extensional origin for the Buchan and Witchground Graben in the North Sea

Seismic refraction and subsidence observations are used to explain the heatflow and subsidence properties of the North Sea.

THE theory of plate tectonics has been very successful in describing the creation of oceanic crust and accounting for the heat flow and subsidence anomalies observed over mid-ocean ridges[1]. However, the theory has not been able to explain the heat flow or subsidence of continental shelves or of epicontinental basins, in particular the Mesozoic and Cenozoic subsidence of the North Sea[2], which is considered here.

The main structural elements of the North Sea are the Viking and Central Graben, which underlie the axis of Tertiary sinking of the North Sea basin. These two major graben meet the Moray Firth Basin in the region of the Forties oil field, which also marks the confluence of the Buchan and Witchground Graben. The North Sea has been a centre of subsidence since the Devonian and although the graben system was initiated in Permo–Triassic times, most of the extension occurred from the Jurassic to Mid-Cretaceous[3]. Major rifting seems to have died out by the start of the Upper Cretaceous, giving way to a broad, general subsidence which allowed the accumulation of chalk, sands from the north-west and finally a thick sequence of Tertiary clays, shales and siltstones.

Although there are many models to account for the formation of shelves and inland basins (see refs 4–6), the most attractive are those based on the concepts used in describing the evolution of lithosphere as it moves away from the mid-ocean ridges[7–9]. In particular, on the basis of a high heat flow and a shallow Moho in the Aegean Sea, McKenzie[8,10] has suggested a simple stretching mechanism to account for the formation of sedimentary basins. In this model, thinning of the lithosphere occurs as a result of large scale extension whereby the surface area is increased by a factor b. If the extension is rapid and lithosphere is conserved, both the crust and the lithosphere decrease in thickness by a factor of $1/b$, causing a fault controlled isostatic subsidence of the surface and creating a thermal anomaly by the passive upwelling of hot asthenospheric material. As the thermal anomaly decays by conduction through the crust, the lithosphere thickens and subsides allowing, in the absence of further extension, the formation of a saucer shaped sedimentary basin. It can be shown[8] that the heat flow and subsidence history of a basin can be predicted as a function of the extension factor. If crustal material is conserved, a measurement of the depth to the Moho will indicate the amount of extension when compared with the Moho depth beneath a non-extended region. We show here that the decrease in Moho depth and increase in subsidence beneath the Witchground and Buchan Graben can be accounted for by a mechanism involving between 50 and 100% stretching of the lithosphere from the Jurassic through to the Mid-Cretaceous.

Seismic refraction data

The Marine Group at Cambridge University undertook the investigation of the velocity structure of the crust and upper mantle along a line parallel to and west of the main axis of Tertiary sinking in the North Sea (Fig. 1). The refraction experiment involved the shooting of three lines into sea bottom seismometers designed and built at Cambridge specifically for this experiment[11]. The main line, reversed over 400 km, was fired across the Witchground and Buchan Graben and was complemented by a shorter crustal control line at each end. Crustal and upper mantle phases were identified from the seismograms and interpretation of the travel time information was made using the method of time term analysis (see ref. 12). Using this approach, each shot and receiver location is assigned a delay time, or time term, which is due to the presence of the overburden between the shot or receiver point and the buried refractor. If the velocity structure in the overburden is known, then the delay time to the refractor beneath a particular site may be inverted to a depth value.

The analysis of the Firth of Forth profile revealed three refractors beneath the sediments with velocities of 5.7, 6.2 and 7.2 km s^{-1}. The Moho velocity is ~8.16 km s^{-1}, a value taken from the Main Line as the Moho refraction was not reliably identified as a first arrival on this profile. The overall depth to the Moho is ~30 km compared with 32–33 km observed for the Moho depth beneath the Southern Uplands as revealed by the LISPB experiment[13]. For the crustal control line at the north, a time term analysis of these arrivals, together with the crustal arrivals from Main Line shots, gave good control over the crustal refractors although the quality of the data was not as high as for the Firth of Forth Line. On the East Shetland Platform, the short range refractions gave a phase velocity of ~4.1 km s^{-1}, which is consistent with Devonian Old Red Sandstone at shallow depth. This overlies an upper crustal layer of 5.7 km s^{-1}, which in turn covers a layer of 6.2 km s^{-1}. Both these values are in good

0028–0836/80/080729—04$01.00

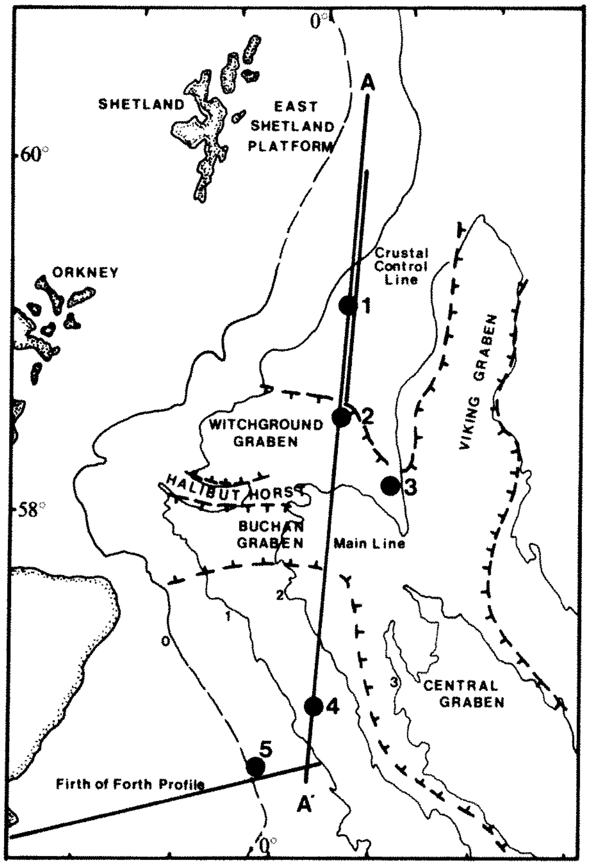

Fig. 1 Seismic refraction lines, drill holes, the major Mesozoic faults and Tertiary isopachs in the Central North Sea. The three refraction lines are the Firth of Forth Line, the Crustal Control Line and the Main Line.

agreement with the velocity structure determined from the Firth of Forth Profile, although difficult correlations make identification of a lower crustal refractor uncertain. On the main north–south line, energetic mantle arrivals were observed on most of the seismograms, but with greatly varying waveform suggesting the superposition of rays. Arrivals were generally well defined and a time term analysis yielded an upper mantle velocity of 8.16 km s^{-1}, which is controlled by good reversed coverage. The delay times to the Moho computed in the analysis increase towards the centre of the line, as does the sediment thickness.

A large number of oil companies have allowed generalised velocity–depth structures to be compiled from their individual well logs. By combining this information with the crustal refraction data already deduced, the Main Line delay times were converted into depths, enabling a seismic section to be constructed (Fig. 2). After stripping off the delay due to the sediments, the Moho has an anticlinal form beneath the sedimentary basin, with the shallowest Moho depth of ~25 km below the deepest sediments. Further north, the Moho deepens again to ~32 km beneath the East Shetlands Platform. The anticlinal structure can cause focusing of the refracted rays to produce the varying waveforms observed. The asymmetric position of the Moho anticline with respect to the centre of the profile can also explain the asymmetric amplitude peaks on the Main Line records, if focusing is admitted. The amplitude peaks are at receiver R3 from the northern shots and receiver R8 from the southern shots[14].

Subsidence data

Basement subsidence as a function of time was estimated in a suite of five holes across the Witchground and Buchan Graben from lithologic and biostratigraphic logs provided by the Shell/Esso, Conoco, Mobil and Amoco oil companies. From these data, the generalised lithologic sections (Fig. 3*a*) were constructed. To calculate the basement depth at a given time, it is necessary to remove the younger sediments, allow for the effects of compaction on the older sediments, compute the isostatic loading effect of the uncompacted sediments and add the water depth at the time of deposition[15,16]. We have ignored the effects of eustatic sea level changes. In the decompaction process, the base of the Upper Permian salt or anhydrite was taken as being basement. As the regression at the end of the Aptian–Albian is an almost basinwide reflective marker at the beginning of the phase of general subsidence, this event has been taken as the datum for plotting the depths of subsequent time–stratigraphic units. This unconformity is evidence that the North Sea was generally close to sea level at the beginning of the Upper Cretaceous, a view which is also supported by reports that shallow-water faunal assemblages have been found in the uppermost Lower Cretaceous[17]. Hence, plots of depth relative to the Aptian–Albian are graphs of approximately true depth below sea level.

In contrast to Clarke[2], who suggested that the subsidence rate was increasing during the Tertiary, we find that the subsidence varies almost linearly with time (Fig. 3*b*). When corrected for the depth of deposition of the sediments, as estimated from faunal assemblages by W. A. Berggren and F. M. Gradstein (personal communcations) and by analysis of the sands at hole 2, the exponential tail off of subsidence rate with time becomes more pronounced. Along the profile the subsidence varies from about 500 m to ~1,300 m, with the greatest amount of subsidence in the centre of the graben which coincides with the shallowest Moho depth.

Discussion

An estimate of the stretching factor can be obtained from the seismic section, assuming that stretching stopped at the base of the Upper Cretaceous and that crustal material has been conserved. The depth from base Upper Cretaceous to the Moho at R5 is ~20 km, while under the East Shetlands Platform (or the Southern Uplands) it is roughly 32 km. This indicates a thinning of about 0.6 or a stretching of 1.6. If the value of 35 km for the depth to the Moho beneath the Shetland Islands is used as the estimate of the thickness of the unstretched part of the lithosphere, a value of 1.7–1.8 is obtained for the stretching factor.

Estimates of the amount of stretching can also be obtained from the amount of post-Lower Cretaceous subsidence. The observed subsidence of the five holes was examined and compared with that predicted by the model for stretching factors of 1.25, 1.5 and 2.0. The subsidence on the flanking blocks of the graben system indicates only sight stretching whereas the subsidence curves within the graben suggest stretching values of between 1.5 and 2.0, which covers the range of values given by the seismic evidence.

The stretching mechanism is supported by the heat flow which is higher than normal[18]. The observed values are obtained from extrapolated Bottom Hole Temperatures and estimates of thermal conductivities, and could well be too high. Reducing these values by only 10% gives a value that is close to that expected if 35 km of continental crust with a mean radiogenic component of heat flux of 0.8 μcal cm^{-2} s^{-1} is stretched by a factor of between 1.5 and 2.0 (Table 1).

Another observation accounted for by this mechanism is the 2–3 km of Middle Jurassic to Lower Cretaceous sediment observed within the graben itself. The initial subsidence is probably dominantly fault controlled and occurred during the extensional process. It is caused by isostatic adjustment as a result of the replacement of light crust by denser asthenospheric material. Given the amount of extension deduced from the seismic and subsidence data, the amount of this initial fault controlled subsidence within the graben may be computed from

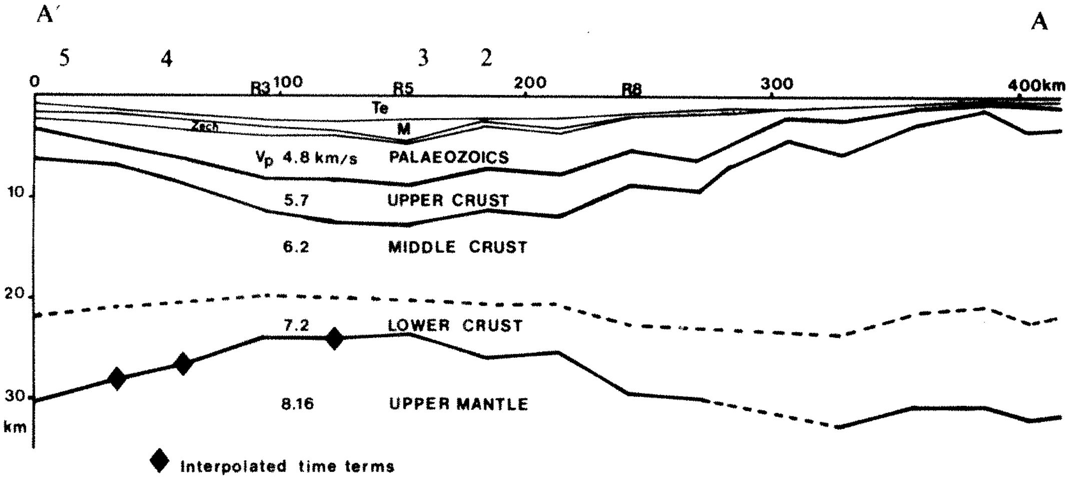

Fig. 2 Velocity depth section obtained along the main refraction profile after inverting time terms to depths. The thickness of the lower crust is constrained to be half the thickness of the middle crust as observed at the southern end of the profile[14]. The projected positions of the drill holes are shown (vertical exaggerated four times).

the model[8,16]. For a stretching factor of 2, ~1.2 km of water-filled or 3 km of sediment-filled subsidence would result. This is very close to the amount of subsidence observed.

Because of the agreement between the observed values of Moho depth, subsidence history and heat flow with the values predicted by the extensional mechanism, we would propose the following model to explain the major features of the development of the North Sea basin. The graben system was emplaced during the Permo–Triassic but with relatively little extension. From the time of the Jurassic through to the Lower Cretaceous, there was significant radial extension with the three parts of the graben system extending by a factor of ~2. The upper crust at least underwent brittle failure, thinning by a factor of ~2 and producing isostatic subsidence within the graben. When extension terminated, a general subsidence, caused by thermal relaxation through the crust, continued and the present saucer-shaped basin developed (Fig. 4). It is not clear from the observations whether the lithosphere extended as much at depth as it did at the surface. If this were the case, the ductile part of the lithosphere could have thinned by less than the brittle crust but over a greater areal extent. Such deformation would replace cold lithosphere by less dense, hot asthenosphere and would cause the graben flanking blocks to rise during extension. The consequent erosion could explain the absence of Jurassic and

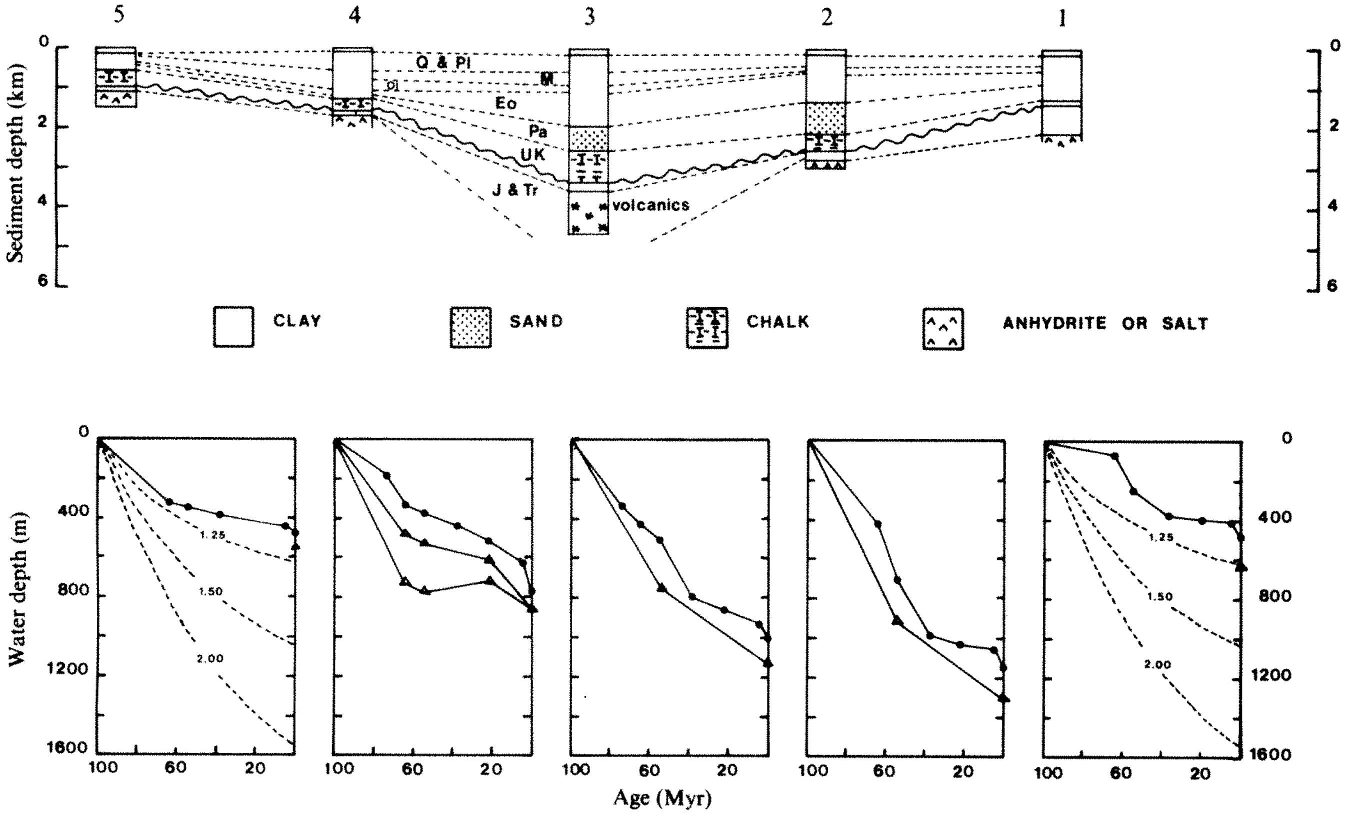

Fig. 3 A lithologic cross-section of the Witchground–Buchan Graben complex showing five wells below line AA′ on Fig. 1. The letters on the cross-section represent standard stratigraphic stages and the symbols represent the different lithologies. (Explicitly: J, Jurassic; Tr, Triassic; UC, Upper Cretaceous; Pa, Palaeocene; Eo, Eocene; Ol, Oligocene; M, Miocene; Pl, Pleistocene and Q, Quaternary.) The inferred post-Upper Cretaceous basement subsidence (●), corrected where possible for depth of deposition (△), is shown below each well. The thermal subsidence curves expected after 25% ($b = 1.25$), 50% ($b = 1.50$) and 100% ($b = 2.00$) instantaneous stretching at 100 Myr are shown on the outer two plots of basement subsidence.

Lower Cretaceous sediments on these blocks. However, the presently available seismic, eustatic and subsidence data are too imprecise to allow the inference that such sub-crustal flow has actually taken place.

This model has been proposed to account for the development of the North Sea basin in the absence of a full discussion of alternative mechanisms. We are drawn to this mechanism in preference to models invoking thermally or gravitationally induced metamorphism in the crust or upper mantle because of the observed decrease in the rate of subsidence with time. Purely flexural subsidence in response to gravitational loading predicts a deeper Moho beneath the thickest sediments, which is inconsistent with the seismic evidence. Crustal attenuation by supra-crustal erosion is rejected because of the presence of thick sequences of pre-Upper Cretaceous sediments over much of the present North Sea basin. The effects of some or all of these mechanisms may be observed in the geological record of the North Sea but we believe that the dominant mechanism in the formation of the basin is that of lithospheric attenuation due to extension.

A major responsibility of the model is to account for the required extension in the geology of the North Sea. This cannot be done by back-tracking such high angle faults as are inferred from most multi-channel seismic lines. However, hitherto unexpected low angle faults have been observed, and secondary high angle faulting is known to have occurred in the area of the Piper oilfield[19], which may be the last of a series of listric faults such as are proposed by Profett[20] to explain the extension in the Basin and Range province of the US. While this difficulty needs to be resolved, we feel that the good agreement between the refraction, heat flow and subsidence data warrants the consideration and further investigation of the model.

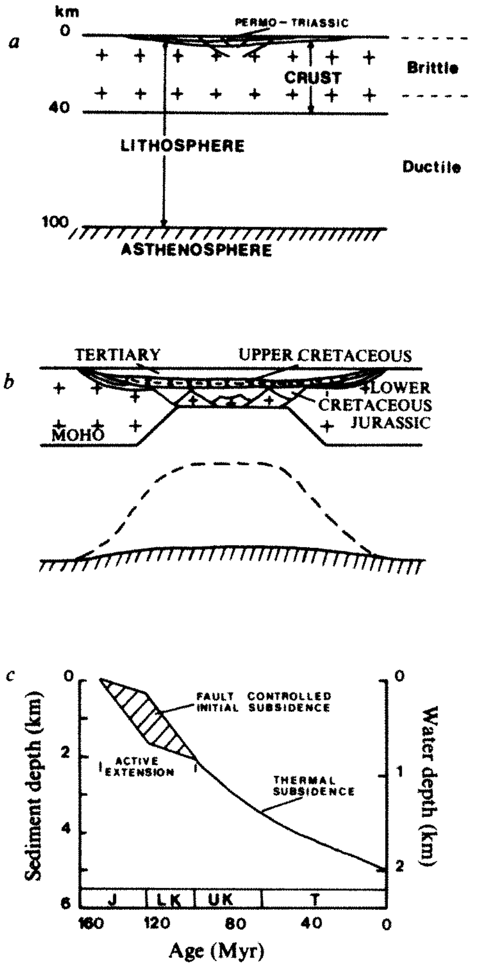

Fig. 4 An outline of the post-Triassic development of the Witchground–Buchan Graben complex. *a*, Initial cross-section before Mid-Jurassic and Lower Cretaceous extension. *b*, Present section after stretching by 100% in the graben. Note the shallow Moho, the localised Jurassic and early Cretaceous section and the widespread Upper Cretaceous and Tertiary. At the beginning of the Upper Cretaceous, the asthenosphere (dashed line) had thinned by a factor of 2. *c*, Conceptual post-Mid-Jurassic subsidence of the centre of the graben complex were the sedimentary supply to match exactly the basement subsidence.

Table 1 Comparison of observations from the centre of the graben with values predicted by the stretching model, for two stretching factors

		Model prediction	
	Observed	1.5	2.0
Fault controlled subsidence, Jurassic to Lower Cretaceous	200–800 m	800 m	1,200 m
Corrected thermal subsidence, Upper Cretaceous to Present	1,100–1,300 m	1,000 m	1,500 m
Type of thermal subsidence	Exponential	Exponential	
Moho depth below Upper Cretaceous	20 km	23 km*	17.5 km*
Heat flow (μcal cm^{-2} s^{-1})	1.70 ± 0.35	1.47 ± 0.3†	1.41 ± 0.3†

* Assuming 35 km thickness of normal crust.
† Assuming 0.8 μcal cm^{-2} s^{-1} radiogenic contribution.

Conclusions

The approach we have taken has been simplistic, and we have ignored such complications as flexure of the lithosphere due to sediment loading and eustatic sea level changes. Even though these factors have been neglected, we believe that the method is justified by the results which show that stretching by a factor of between 1.5 and 2.0 in the Jurassic and Lower Cretaceous can account for the shallow Moho, subsidence history and present heat flow across the Witchground–Buchan Graben complex. We feel that this study demonstrates the power of comparing seismic refraction and subsidence observations in unravelling the geologic history of the North Sea basin and we suggest that such comparisons may be as useful in investigating other basins. In particular, these studies may be of value to the oil industry because, if the stretching factor can be determined, it should be possible to predict the palaeo-heat flow and hence the degree of thermal maturation of the individual sedimentary horizons[16].

We thank representatives from the Shell, Conoco, Mobil and Amoco oil companies, for access to well logs which, with their experience and that of P. Ziegler, have led us through the complexities of the Mesozoic and Cenozoic sedimentary history of the North Sea.

An immunoglobulin heavy-chain gene is formed by at least two recombinational events

Mark M. Davis*, Kathryn Calame*, Philip W. Early*, Donna L. Livant*, Rolf Joho†, Irving L. Weissman† & Leroy Hood*

* Division of Biology, California Institute of Technology, Pasadena, California 91125
† Laboratory of Experimental Oncology, Department of Pathology, Stanford Medical School, Stanford, California 94305

The events of B-cell differentiation can be reconstructed in part through an analysis of the organisation of heavy-chain gene segments in differentiated B cells. A mouse immunoglobulin α heavy-chain gene is composed of at least three noncontiguous germ-line DNA segments—a V_H gene segment, a J_H gene segment associated with the C_μ gene segment, and the C_α gene segment. These gene segments are joined together by two distinct types of DNA rearrangements—a V–J joining and a C_H switch.

THE antibody genes provide a unique opportunity for studying the molecular basis of one pathway of eukaryotic differentiation because the rearrangement of gene segments is correlated with the expression of antibody molecules. Antibody molecules are encoded by three unlinked gene families—λ, κ and heavy chain (H)[1]. The λ and κ families encode light (L) chains and the heavy-chain family encodes heavy chains. The light chains are encoded by three gene segments, V_L (variable), J_L (joining) and C_L (constant), which are separated in the genomes of cells undifferentiated with regard to antibody gene expression[2,3]. During differentiation of the antibody-producing or B cell, the V_L and J_L gene segments are rearranged and joined together while the intervening DNA between the J_L and C_L gene segments remains unmodified[2-4]. This process of DNA rearrangement is termed V–J joining. During the expression of the rearranged gene in the differentiated B cell, the coding regions as well as the intervening DNA between the J_L and C_L gene segments are transcribed as part of a high molecular weight nuclear transcript. The intervening region is then removed by RNA splicing to produce a light-chain mRNA with contiguous V_L, J_L and C_L coding segments[5,6]. Recently, we demonstrated that the heavy chain contains three analogous gene segments, V_H, J_H and C_H, which undergo a similar type of V–J joining during B-cell differentiation[7-9]. Each antibody-producing cell synthesises only one V_LJ_L polypeptide sequence and one V_HJ_H sequence, which together form the antigen-binding (V) domain of the antibody molecule.

The heavy-chain genes seem to have a special role in the differentiation of the antibody-producing cell as reflected in a second phenomenon known as the switching of heavy-chain constant regions or C_H switching. Antibody molecules can be divided into five different immunoglobulin classes—IgM, IgD, IgG, IgA and IgE—which are determined by one of eight distinct heavy chain genes [that is, C_μ, C_δ, ($C_{\gamma1}$, $C_{\gamma2a}$, $C_{\gamma2b}$, $C_{\gamma3}$), C_α and C_ϵ]. Each class of immunoglobulin seems to be associated with unique functions such as complement fixation or the release of histamine from mast cells. The process of B-cell differentiation is complex and a variety of conflicting views exists on the transitional stages. It is generally agreed, however, that IgM is the earliest immunoglobulin class that is expressed in the differentiation of a B cell (see ref. 10). The immature B lymphocyte apparently has the capacity to differentiate along a variety of discrete pathways and produce progeny which may switch from IgM expression to the expression of any one of the other classes of immunoglobulins. The terminal stage of B-cell differentiation is the plasma cell, which is committed to synthesise and secrete large quantities of a single molecular species of antibody. Several studies suggest that the specificity or V domain does not change as different immunoglobulin classes are expressed throughout this differentiation process[11-15]. During C_H switching, light-chain expression remains unaltered.

We are interested in studying the molecular mechanisms which permit a B cell (or its progeny) to express successive classes of antibody molecules. Here we demonstrate that an α heavy-chain gene derived from a terminally differentiated plasma cell is composed of three noncontiguous germ-line DNA segments. These gene segments are joined together by at least two distinct DNA rearrangements—a V–J joining and a C_H switch.

Organisation of the α heavy-chain gene is altered in differentiated as opposed to undifferentiated DNAs

We have constructed 'libraries' of recombinant phage[16] containing large (12–20 kilobases) inserts of mouse DNA in the vector Charon 4A (ref. 17). These libraries contain sufficient numbers of recombinants ($\sim 10^6$) for there to be a high probability that most single-copy sequences of a given genome are included. We have previously reported the construction of such a library from the DNA of the mouse IgA-producing myeloma tumour M603, and the subsequent isolation and characterisation of clones containing rearranged or differentiated genomic DNA. These clones, CH603α6 (α6) and CH603α125 (α125), have V_H and C_α gene segments on a single fragment of DNA[7,8]. The *Eco*RI restriction maps of these clones are shown in Fig. 1*a*. The α6 clone has three *Eco*RI fragments—one 7.3 kilobases long containing the V_H gene segment, a second of 5.1 kilobases containing the 5′ portion of the C_α gene segment, and a third of 4.4 kilobases containing the 3′ portion of the C_α gene segment. Approximately 6.8 kilobases of intervening DNA separate the V_H and C_α gene segments. The α125 clone also has three *Eco*RI fragments—one of 6.5 kilobases which is located on the 5′ side of the 7.3- and 5.1-kilobase *Eco*RI fragments also described for α6.

The genomic clones were isolated using a cloned cDNA plasmid representing the entire heavy-chain mRNA of the IgA-producing tumour S107 (denoted S107 cDNA)[7]. The S107 V_H region is about 98% homologous to the M603 V_H region at the nucleotide level[9]. Analysis by the Southern blot procedure[18,19] of *Eco*RI-digested M603 DNA hybridised to the S107 cDNA probe demonstrates the presence of three *Eco*RI fragments corresponding to those described above in the α6 clone[7]. Thus, the rearranged α6 clone is not an artefact of the cloning or isolation procedures.

When the S107 cDNA probe is used to examine a Southern blot of *Eco*RI-digested sperm or embryo DNA, a somewhat different pattern is observed[8]. In particular, the 5.1-kilobase

0028–0836/80/080733—07$01.00

*Eco*RI fragment containing most of the large intervening sequence and the 5′ portion of the C_α gene segment is not present. This observation indicates that the α6 clone is the product of one or more DNA rearrangements which presumably occurred during B-cell differentiation[8].

The α gene is composed of at least three different germ-line segments of DNA

In view of the possibility that lymphocytes earlier in the M603 lineage might first have produced IgM molecules and later IgA molecules, we decided to investigate the possible contribution of germ-line C_μ sequences as well as V_H and C_α sequences to the myeloma α gene (Fig. 1*a*). We constructed several libraries of germ-line DNA (sperm) and proceeded to isolate clones containing V_H, C_μ and C_α gene segments using cloned cDNA probes (denoted S107 V_H, C_α and C_μ) for the corresponding coding regions and the screening procedure of Benton and Davis[20]. *Eco*RI restriction maps of several germ-line clones are shown in Fig. 1*b*. We chose sperm (germ-line) DNA for our undifferentiated genomic libraries to eliminate any possibility of DNA rearrangements which may occur in somatic tissues during embryogenesis. The C_α and V_H clones seem to be representative of germ-line sequence organisation because the *Eco*RI fragments containing the corresponding coding regions (in the clones) are identical in size to those found in the Southern blot analysis of undifferentiated DNA with C_α and S107 V_H cloned cDNA probes—9.5 and 7.4 kilobases, respectively (Fig. 2*a*–*d*). The V_H and C_α probes were derived from restriction fragments of the S107 cloned cDNA[7] extending from approximately the 5′-untranslated region to codon 108 (V_H) and from codons 108 to 274 (C_α). Figure 2*a* shows that a Southern blot of a germ-line

Fig. 1 *a*, α Heavy-chain clones isolated from a genomic library of myeloma M603 DNA. CH603 α6 and CH603 α125 are two overlapping clones derived from a partial *Eco*RI library of M603 DNA, constructed using the phage Charon 4A (ref. 7). The position of the respective gene segments, as well as their direction of transcription, was determined by R-loop mapping and restriction analysis[7,8]. *b*, Germ-line V_H, C_μ and C_α clones isolated from a genomic library of sperm DNA from inbred BALB/c mice. Sperm DNA[33,34] was partially digested with restriction enzymes in two ways: (1) with a mixture of *Hae*III plus *Alu*I and (2) with *Eco*RI alone. After digestion in conditions designed to maximise the yield of 12–20-kilobase fragments, these fragments were selected on sucrose gradients. The *Hae*III/*Alu*I fragments were methylated with *Eco*RI methylase and blunt end ligated with synthetic *Eco*RI cleavage sites and then cleaved with *Eco*RI essentially as described previously[16] except that *Eco*RI linker ligations were done at 18 °C to lessen the endonuclease degradation. Both types of fragments were then ligated to the isolated arms of the bacteriophage Charon 4A (ref. 16) at 4 °C. The enzymatically recombined DNAs were packaged *in vitro* using the strains of Sternberg[35] and the protocol of Hohn[36]. The efficiency of packaging was 400,000 plaque forming units (PFU) per μg inserted DNA in the case of *Eco*RI partially digested DNA and 200,000 PFU per μg for *Hae*III/*Alu*I digestions. The background of non-recombinant Charon 4A was 25% and <5%, respectively. Approximately 500,000 *Eco*RI and 1,200,000 *Hae*III/*Alu*I clones were constructed and amplified. A library of ~500,000 clones provides a 90% chance of finding a given single copy sequence and a library of 1,200,000 clones a 99% chance[37]. The use of enzymes that recognise three different sequences reduces the possibility that a particular region of interest is lost from the library because it had too many or too few restriction sites to fall within the sucrose gradient size cut. Libraries were screened[7,16] with the cDNA clone (see text) S107 or M104E C_μ cloned cDNA probes identified by DNA sequence analysis[9,38]. The C_μ clone used extends from codon 300 to the 3′-untranslated region (~1,000 base pairs).[38]. Independent overlapping clones were obtained from the C_α and C_μ gene segments. Location of the coding regions and the direction of transcription were determined by DNA sequence analyses for the CHSp PC-3 clone, by heteroduplex analyses with the α6 clone for the CHSp α29 clone, and by R-loop mapping and restriction analyses of the CHSpμ27 clone[38]. The germ-line genomic clones will be denoted μ27 (CHSpμ27), V_H3 ($CHSpV_H3$), and α29 (CHSpα29).

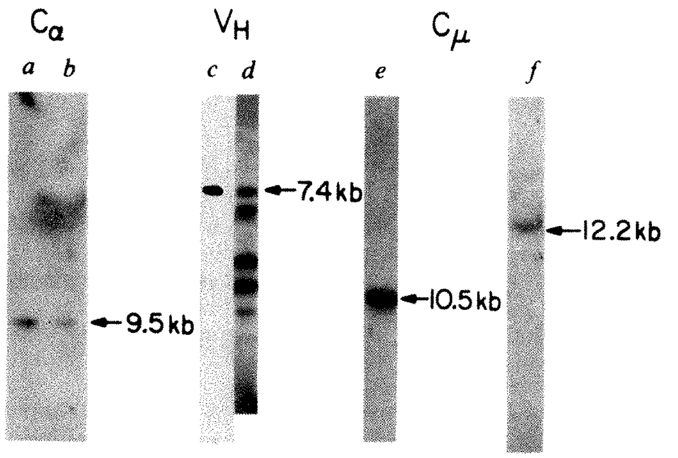

Fig. 2 Southern blot analyses of C_α, C_μ and S107 V_H coding regions in germ-line DNA. Approximately 3–20 μg of sperm DNA or 13-day embryo was digested with *Eco*RI and electrophoresed on a 0.7% neutral agarose gel for 10–12 h at 30–40 V. Gels were then blotted according to the procedures of Southern and Flavell[18,19] and hybridised with ^{32}P nick-translated cDNA[39]. Washing was for 1.5 h in 1 M NaCl, 1 M Tris *p*H 8, 0.1% SDS and 0.1% sodium pyrophosphate at 65 °C and for 1 h in 1×SSC, 0.1% SDS and 0.1% sodium pyrophosphate. Lanes *a* and *b* are α29 and embryo DNAs, respectively, hybridised to the C_α cDNA probe. Lane *c* is V_H3 DNA hybridised to the S107 cDNA probe. Lane *d* is sperm DNA hybridised to the S107 V_H cDNA probe. This probe cross-reacts with eight or nine closely related V_H gene segments[8]. Lanes *e* and *f* are μ27 and sperm DNAs, respectively, hybridised to the C_μ cDNA probe. Identical results in all cases were obtained with BALB/c 13-day embryo DNA or sperm DNA as has been found for a V_κ gene[34]. Sizes (given in kilobases) were determined by comparison with restriction fragments of PBR322 (ref. 40) or by the use of PBR322 multimers generated by *Bam*HI cleavage of PBR322 and limited ligation of the resulting monomer.

C_α clone (α29) digested with *Eco*RI and hybridised with the C_α cDNA probe yields a 9.5-kilobase fragment. A similar analysis of embryo DNA produces a band of identical size (Fig. 2*b*). Southern blots of a germ-line V_H clone (V_H3) and embryo DNA digested with *Eco*RI and hybridised to a S107 V_H cDNA probe gave, respectively, a 7.4-kilobase fragment (Fig. 2*c*) and several fragments including a 7.4-kilobase fragment (Fig. 2*d*). An important question is the relationship between the germ-line V_H3 and myeloma M603 V_H coding regions because there are at least eight V_H gene segments that hybridise to the S107 probe[8]. The germ-line V_H3 DNA sequence codes for the S107 V_H protein sequence[9] and, accordingly, differs from the M603 V_H region by a minimum of four base changes leading to three amino acid subsitutions[21]. Thus, the germ-line V_H3 and the myeloma M603 V_H gene segments may be encoded by two distinct germ-line V_H gene segments or the V_H3 gene segment may give rise to the M603 V_H gene segment by somatic mutation and selection. As we shall show subsequently, the V_H3 clone seems to be indistinguishable from the M603 clone in the V_H coding region and in more than 11-kilobases of 5'-flanking sequence by heteroduplex and restriction enzyme analyses. Therefore, our analyses of the localisation of V_H sequences in the myeloma α6 clone are valid because the germ-line V_H clone serves as a probe for the M603 V_H gene and its attendant 5'-flanking sequence.

The *Eco*RI fragment of the germ-line C_μ clone containing the C_μ coding region is smaller (10.5 kilobases; see Fig. 2*e*) than its counterpart seen on a Southern blot analysis of sperm DNA with a cloned μ cDNA probe (12.2 kilobases; see Fig. 2*f*). We believe this discrepancy arises from one (or more) deletion(s) in the DNA flanking the C_μ coding region during the propagation of the recombinant phage. In isolating μ clones from the M603 library, we obtained several 9.5–10-kilobase *Eco*RI fragments containing C_μ coding regions, whereas Southern blot analysis of M603 DNA with a cloned C_μ cDNA probe demonstrated a genomic fragment of 12.2 kilobases, as in the sperm DNA (data not shown). Attempts to isolate C_μ clones from a library of mouse liver DNA have led to similar results (N. Newell and F. Blattner, personal communication). We will present restriction enzyme data below which demonstrate that this apparent deletion in the μ clone does not affect our general conclusions.

The germ-line V_H, C_α and C_μ clones were compared with the myeloma α6 and α125 clones by heteroduplex analysis. Representative heteroduplexes from each of these comparisons show extensive homologies. The germ-line V_H clone shares approximately 11.6 kilobases of homology with the myeloma α125 clone (Fig. 3*a*). This homology extends from the 5' end of the α125 clone up to and including the V_H coding region. The germ-line C_μ clone shows 5.0 kilobases of homology with the large intervening sequence of the myeloma α6 clone (Fig. 3*b*). Starting at its 3' end, the germ-line C_α clone has about 6.4 kilobases of homology with the myeloma α6 clone (Fig. 3*c*). The heteroduplex measurements for these analyses are given in Table 1.

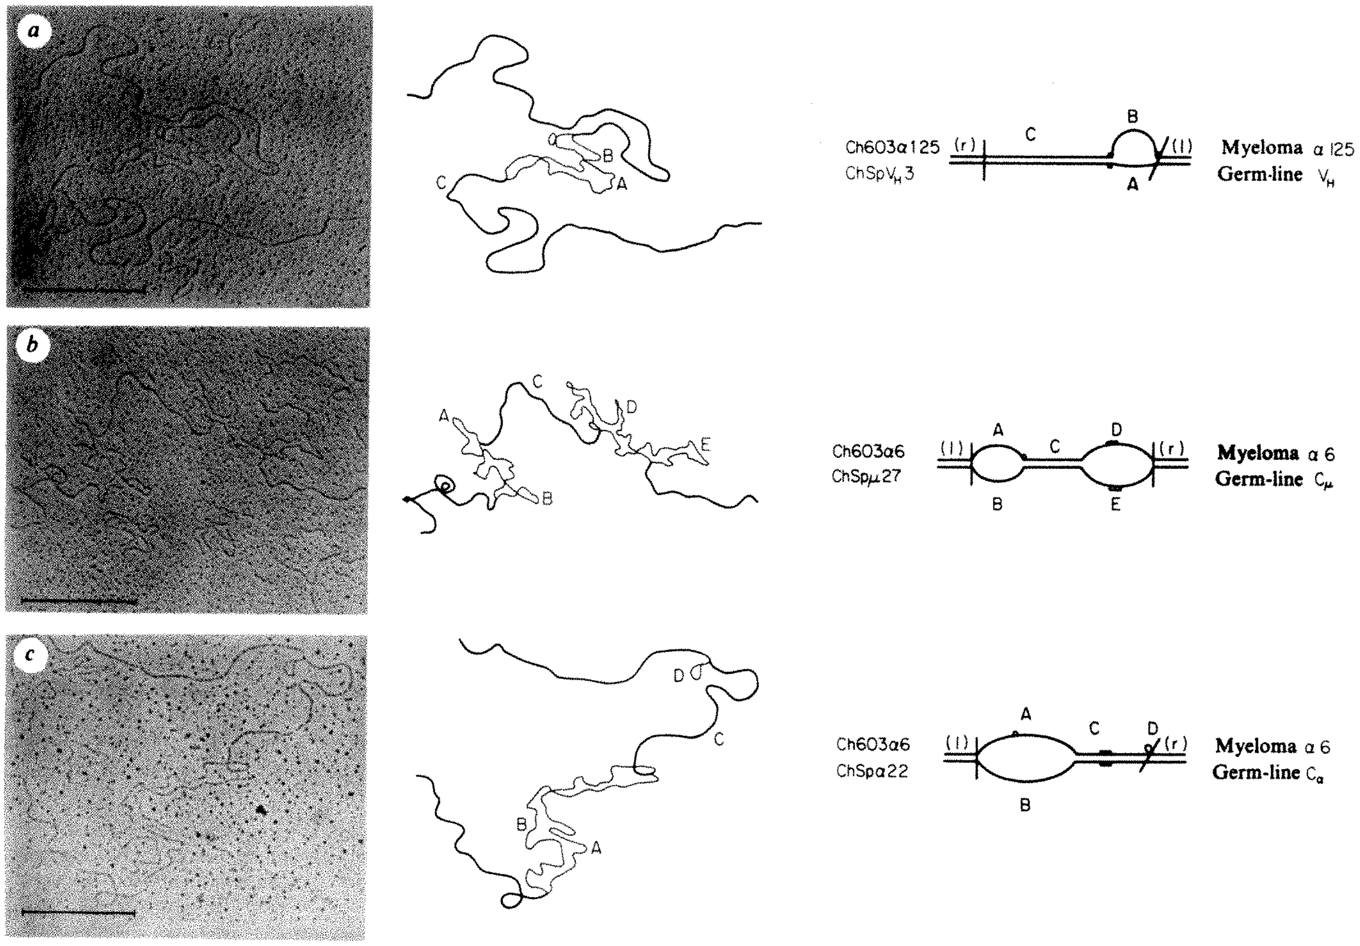

Fig. 3 Heteroduplex analyses of germ-line and somatic clones. The electron micrographs are shown on the left, tracings of these heteroduplexes in the middle and diagrammatic representations on the far right. *a*, Myeloma α125/germ-line V_H PC3. *b*, Myeloma α6/germ-line μ27. *c*, Myeloma α6/germ-line α22. Letters A–E indicate single-strand and double-strand regions for which measurements are given in Table 1. In corresponding line drawings, (r) and (l) refer to the right and left arms of the λ vector. Blocks indicate coding regions in these figures, CsCl purified phage particles were treated with 0.1 M NaOH for 10 min at 20 °C to lyse the phage and denature the DNA simultaneously. After neutralisation of the mixture, the DNA was allowed to reanneal in 50% (v/v) three times recrystallised formamide for 45 min at 20 °C before spreading for electron microscopy[41].

Table 1 Measurements of heteroduplex molecules

Heteroduplex	No. of Molecules	Distance in kilobases A	B	C^+	D	E
a						
Myeloma α125/ germ-line V_H3	35	4.5 ± 0.4	7.2 ± 0.7	11.6 ± 0.4		
b						
Myeloma α6/ germ-line μ27	30	4.8 ± 0.5	5.1 ± 0.5	5.0 ± 0.4	6.7 ± 0.4	7.5 ± 0.5
c						
Myeloma α6/ germ-line α22	26	9.3 ± 0.5	10.4 ± 0.9	6.4 ± 0.5	1.2 ± 0.2	

Measurements were standardised relative to two circular DNA molecules on the same grid [single-strand ΦX174 DNA (5,375 bases) and double-strand pBR322 DNA (4,365 base pairs)]. Letters refer to regions indicated in Fig. 3. The complete clone designations are given in Fig. 3. In heteroduplex *a*, C refers to the region of duplex between the germ-line V_H clone and the myeloma clone. A and B are the non-homologous single strands of these clones. Similarly, C for heteroduplexes *b* and *c* refers to the duplexes formed between myeloma and germ-line C_μ or C_α clones.

Comparative restriction analyses confirm and extend the heteroduplex data discussed above. A detailed restriction map for the M603 myeloma clones was obtained by double digestion with pairs of restriction enzymes and is shown in Fig. 4*a*. To compare the placement of these cleavage sites with those of the germ-line clones, the 5.1-kilobase restriction fragment of the α6 clone (Fig. 1*a*) that spans the region joining the germ-line C_α and C_μ sequences was subcloned. Using this fragment as a probe, detailed restriction comparisons of the myeloma α6 clone and the germ-line C_μ and C_α clones were made. Representative data are shown in Fig. 5 for these comparisons. Figure 5*a*, *b* and *c* represents *Hin*cII plus *Eco*RI digestions of the myeloma α6 5.1-kilobase RI fragment, the germ-line α29 clone and the germ-line C_μ clone, respectively. These digests were electrophoresed on an agarose gel, blotted onto a nitrocellulose filter and hybridised with the labelled 5.1-kilobase RI fragment. This enables homologous restriction fragments to be identified rapidly and precisely (arrows indicate identical fragments). Figure 5*d*, *e* and *f* shows a similar analysis using *Hin*dIII plus *Eco*RI digestions, respectively, of the myeloma 5.1-kilobase subclone, the germ-line α29 clone and the germ-line μ27 clone. These data, as well as additional restriction analyses of the germ-line V_H3 clone, demonstrate that 4 out of 4 restriction sites in the germ-line V_H3 clone, 10 out of 10 sites in germ-line α29 clone and 9 out of 10 sites in the germ-line μ27 clone corresponded exactly to those found in the myeloma α6 clone (Fig. 4). Not only do these restriction analyses independently confirm the heteroduplex results, but they also suggest that the component germ-line sequences of the α6 clone are very similar to their germ-line counterparts. Thus, the heteroduplex and restriction analyses demonstrate that the germ-line V_H gene segment and its 5′-flanking sequence, although not identical to its M603 counterpart, are very similar and may be used to analyse V_H gene segment organisation in the myeloma M603 clones.

DNA sequence analyses of the myeloma α6 clone and the germ-line μ27 clone have demonstrated that the heavy-chain gene family does have distinct V_H and J_H gene segments in the germ line[9]. Moreover, the germ-line J_H gene segment corresponding to that expressed in the myeloma α6 clone is associated with the germ-line C_μ gene[9]. This J_H gene segment contains the *Hha*I site that marks the end of the homology between the germ-line μ27 clone and the myeloma clones (Fig. 4). Accordingly, the distinct germ-line V_H and germ-line J_H gene segments are rearranged in the myeloma clones in a manner analogous to the V_L and J_L gene segments of myeloma light chain genes[2,3].

Although it seems unlikely, the M603 J_H gene segment and flanking sequences could have been fused to a germ-line C_μ clone as the result of some cloning artefact. To eliminate this possibility, we decided to demonstrate the germ-line association of the J_H flanking sequence and C_μ sequences by Southern blot analyses. On different slots of the same agarose gel, we electrophoresed mouse sperm DNA cleaved with either *Hin*cII or *Eco*RI, transferred these DNAs to a nitrocellulose filter and hybridised one lane of each digest with a C_μ probe and a second lane with the 5.1-kilobase *Eco*RI fragment from the intervening sequence of the myeloma α6 clone (Fig. 6). Figure 6*a* and *b* shows Southern blots of *Eco*RI-digested sperm DNA hybridised with the C_μ cDNA probe and the 5.1-kilobase *Eco*RI subclone from the α6 clone, respectively. In both lanes, a 12.2-kilobase band corresponding to the germ-line C_μ fragment can be identified. In a second digest (*Hin*cII) of mouse sperm DNA, a similar result is obtained with both the C_μ probe (Fig. 6*c*) and the 5.1-kilobase *Eco*RI subclone (Fig. 6*d*) hybridising to a 9.3-kilobase *Hin*cII fragment. The 9.5-kilobase *Eco*RI band in Fig. 6*b* and the 5.0-kilobase band in Fig. 6*d* correspond to C_α restriction fragments. In each case, one of the two bands from the 5.1-kilobase *Eco*RI probe co-migrated with the single C_μ DNA fragment. This analysis shows that at least part of the intervening sequence from the myeloma α6 clone is adjacent to the C_μ gene in the germ line. Thus, the apparent deletion in the germ-line μ27 clone is not a significant factor in our discussion.

A summary of these analyses is presented in Fig. 7. The myeloma α6 clone is composed of three noncontiguous germ-line gene segments: (1) a V_H gene segment and its 5′-flanking

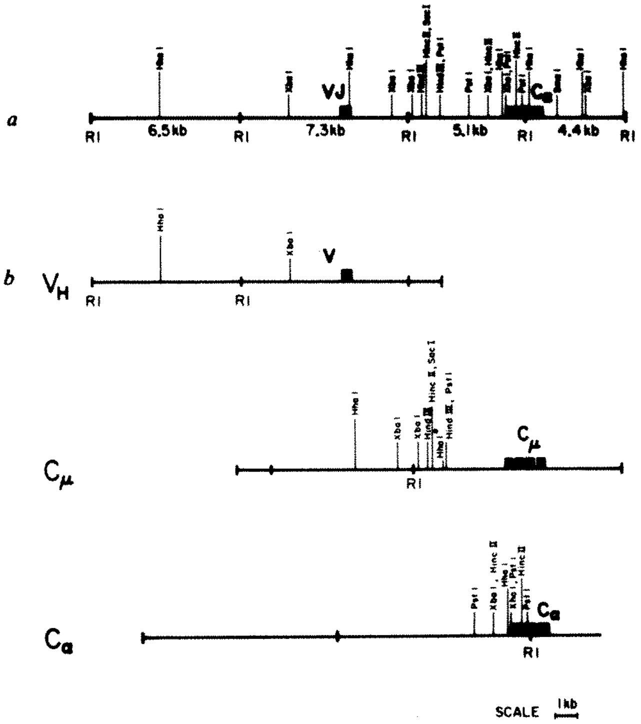

Fig. 4 *a*, Restriction map of myeloma clones α6 and α125. Specific cleavage sites were determined using double enzyme digestion and sizing by gel electrophoresis. Size standards were restriction digests of PBR322 and PBR322 multimers (see Fig. 2 legend). *Hin*dIII, *Hin*cII, *Pst*I and *Sac*I cleavage sites are only shown for the 5.1-kilobase *Eco*RI fragment. *b*, Restriction sites corresponding to those of the myeloma clones detected in the V_H, C_μ and C_α germ-line clones (Fig. 1). Restriction sites in regions corresponding to the 6.5- and 7.3-kilobase RI fragments of α6 and α125 were mapped by double digestion as above. All sites within the 5.1-kilobase RI fragment were compared by co-migration and blotting as described and illustrated in Fig. 5. The *Hha*I site marked by an asterisk in the C_μ clone was the one site found not to conform with those of the myeloma α6 clone.

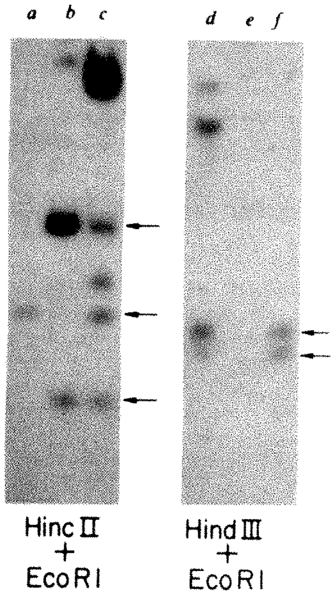

Fig. 5 Comparative restriction digests of the α6 myeloma, germ-line C_μ and C_α clones. Lanes *a–f* show parallel *Hin*cII + *Eco*RI and *Hin*dIII + *Eco*RI digests of the 5.1-kilobase *Eco*RI subclone of the α6 clone (Fig. 1*a*) and DNA from the germ-line α29 and μ27 clones (Fig. 1*b*). Samples were electrophoresed in 1% agarose, transferred to nitrocellulose and hybridised with nick-translated 5.1-kilobase α6 subclone DNA. The co-electrophoresis of restriction fragments allows a large number of different restriction sites to be compared rapidly. In this way, all 16 mapped sites in the 5.1-kilobase α6 subclone were compared with equivalent sites on the α29 and μ27 clones. Arrows show coincident bands.

sequence, (2) flanking sequences located 5′ to a germ-line C_μ gene which includes the J_H gene segment, and (3) the germ-line C_α gene segment with its flanking 3′ and 5′ sequences. Note that within the limits of the methods used here these three germ-line gene segments and their attendant flanking sequences apparently cover the entire myeloma α6 clone.

The α heavy-chain gene is formed by at least two recombinational events

Two distinct DNA rearrangements have occurred to form the M603 α gene—V–J joining and C_H switching (Fig. 8)[9]. The simplest interpretation of these observations is that the V_H gene segment is first joined to a J_H gene segment linked to the C_μ gene segment. This V–J joining, analogous to that which occurs in light chains, generates a rearranged μ gene that presumably leads to the expression of IgM molecules. V–J joining also commits an individual lymphocyte to the expression of a single V domain that remains invariant throughout subsequent steps of B-cell differentiation. Later, a C_H switch joins the V–J gene segment to the C_α gene segment to create a functional α gene and thus enables the differentiated lymphocyte to express IgA molecules. Thus, the myeloma α6 heavy-chain gene is assembled by two distinct and presumably independent DNA rearrangement events. Our heteroduplex, Southern blot and restriction mapping data show unequivocally that these two rearrangements occur at two distinct sites in the genome. These two sites of rearrangement are termed the V–J joining site and the C_H switch site, respectively.

These data are consistent with a differentiation pathway in which a B cell may switch from IgM to IgA synthesis while expressing the same V domain. We cannot establish that these two DNA rearrangement events occurred at different times, although this supposition is reasonable. We also cannot rule out the possibility of intermediate differentiation states in this B-cell lineage where IgG molecules were produced, although there is no direct evidence for such a stage.

The C_H switch may be explained by any one of several genetic models

Several mechanisms of C_H switching have been proposed[11,22–26], many of which are similar to those proposed for V–J joining[27]. These models can be categorised as involving either DNA rearrangements to replace one constant region with another (successive deletions, excision–insertions or inversions) or the differential processing of a large nuclear RNA transcript containing multiple heavy-chain constant-region genes[26].

The RNA processing model seems unlikely as a general mechanism for C_H switching at the level of antibody-secreting plasma cells. High molecular weight nuclear RNAs from three myeloma tumours hybridise only with a cDNA probe complementary to the class of immunoglobulin expressed in that tumour and not with probes from non-expressed immunoglobulin classes[28]. Moreover, cell fusion experiments hybridising two different myeloma cells demonstrate that the hybrid cells synthesise only parental V_HC_H combinations[29], a result in conflict with the simple RNA processing model. Furthermore, neither $C_{\gamma1}$ nor C_μ DNA probes hybridise on Southern blots with the M603 α clones (data not shown), contrary to one prediction of the RNA processing model.

On the other hand, the evidence presented here strongly supports DNA rearrangement as a fundamental element in the mechanism for heavy-chain switching. As summarised in Fig. 7, a very large segment of C_μ flanking sequence has been brought adjacent to C_α and V_H gene segments in the active α gene of myeloma tumour M603. The creation of the M603 α gene apparently requires two DNA rearrangements (Fig. 8). A C_H switching

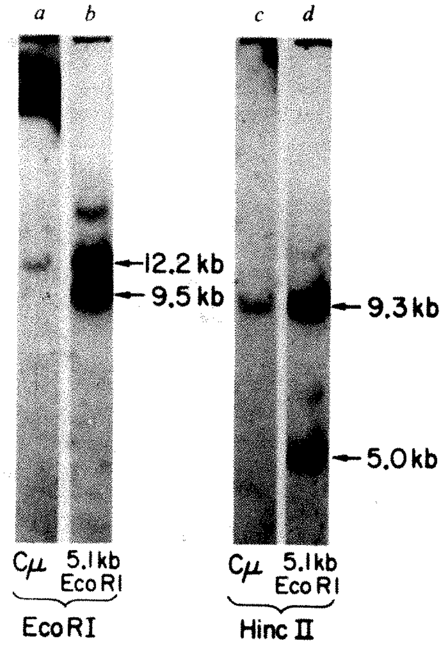

Fig. 6 Southern blots of the 5.1-kilobase *Eco*RI and C_μ fragments. Mouse sperm DNA was digested with *Eco*RI or *Hin*cII and 3 μg was loaded onto a 4 mm × 20 × 20 cm 0.7% agarose gel, electrophoresed at 40 V for 10 h and blotted as described. Probes used were either the 5.1-kilobase *Eco*RI fragment or a C_μ cDNA clone nick-translated to 4×10^8 c.p.m. per μg. Washing was as described in Fig. 3 legend except that lanes hybridised with the 5.1-kilobase *Eco*RI fragment were washed further in 10 mM NaCl, 10 mM Tris, 0.1% SDS and 0.1% $NaPP_i$ for 2 h at 68 °C to reduce the signal strength of weakly homologous repeats. Filters were exposed for 12 h with an intensifying screen at −80 °C. The faint band above the 12.2-kilobase band in *b* is a partial digestion product. All lanes shown were run on the same gel and blotted simultaneously, alignment being assisted by inclusion of pBR322 multimers as internal standards (see Fig. 2).

DNA rearrangement is not postulated in the RNA processing models[26]. The data presented here do not distinguish between the various types of DNA rearrangements proposed, but the hybridisation kinetics experiments of Honjo and Kataoka are consistent with a deletional mechanism for the C_H switch[25]. In addition, recent experiments suggest that V–J joining in mouse λ genes is accomplished by a deletional mechanism[4]. Thus, both types of DNA rearrangement, V–J joining and C_H switching, may arise through deletional mechanisms. If the deletional model is correct for either type of DNA rearrangement, the differentiation of B cells is irreversible because chromosomal information is lost with the excision of each deletional loop of chromosome.

Gene organisation studies may delineate distinct pathways of B-cell differentiation

It will be interesting to determine whether all joined α genes have the same switch site. Southern blot analyses of the DNA from a second IgA-producing myeloma tumour, H8, with the 5.1-kilobase *Eco*RI probe yield a restriction fragment pattern identical to that of M603 DNA (data not shown). In particular, the 5.1-kilobase *Eco*RI fragment (Fig. 1) which contains the switch site seems the same. These data suggest that the expressed α genes in both M603 and H8 myeloma tumours have the same C_H switch site. However, Southern blot analyses of several other closely related IgA-producing tumours do not show a 5.1-kilobase *Eco*RI fragment (M.M.D., unpublished observation). Thus, there may be multiple C_H switch sites for the C_α gene segment. As it seems that B cells producing IgM or IgG may switch to the production of IgA, perhaps distinct C_H switch points reflect distinct pathways of B-cell differentiation. It will also be interesting to determine the location and number of switch sites for other immunoglobulin classes. If each C_H gene segment has a unique site or set of sites for C_H switching, one may be able to trace the distinct pathways of B-cell differentiation by studying the sequence organisation of each functional heavy-chain gene.

DNA rearrangements of antibody gene segments lead to combinatorial amplification of immunoglobulin information

V–J joining and C_H switching are mediated by DNA rearrangements which display combinatorial properties that amplify the germ-line information encoding the antibody gene families. (1) The V and J gene segments of one antibody gene family may be joined in a combinatorial manner to generate diversity in the third hypervariable regions of both κ and heavy chains[4,8,9,30,31]. For example, mice may have at least 200 V_H and 5 J_H gene segments that may be joined combinatorially to generate 1,000 different V_HJ_H coding regions. (2) One V domain may be combinatorially switched among eight or more different C_H regions to carry out a variety of different effector functions that are directed at eliminating antigen or triggering defensive mechanisms such as complement fixation. Thus, each recognition (V) domain may be switched to many different effector (C) domains. The combinatorial properties of antibody gene segments and polypeptides therefore contribute to several fundamental aspects of the vertebrate immune response—V region diversity and the combinatorial switching of antigen-recognition (V) domains with a variety of different effector (C) domains during B-cell differentiation. Other complex eukaryotic gene families may use similar DNA combinatorial mechanisms for information amplification[32].

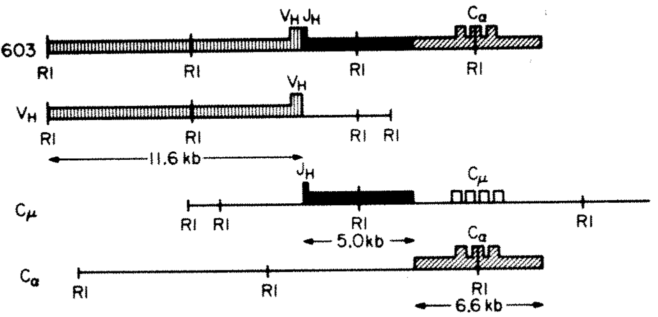

Fig. 7 Origins of the three germ-line components of the myeloma α heavy-chain gene. Various types of shading indicate homology by heteroduplex analyses and by restriction enzyme analyses.

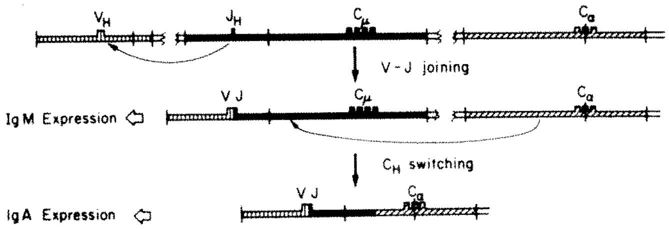

Fig. 8 Two types of DNA rearrangements leading to the creation of the myeloma α heavy-chain gene V–J joining and C_H switching. V–J joining indicates a DNA rearrangement that joins the V_H and J_H gene segments. Because the J_H segments seem to be associated with the germ-line C_μ gene[9], V–J joining permits a μ chain and IgM molecules to be expressed by the differentiating B cell. C_H switching denotes a DNA rearrangement that replaces the C_μ gene segment with a C_α gene segment. This second rearrangement presumably permits an α chain and IgA molecules to be expressed by the now fully differentiated lymphocyte.

The primary structure of 16S rDNA from *Zea mays* chloroplast is homologous to *E. coli* 16S rRNA

Zs. Schwarz[*] & H. Kössel[†]

Institut für Biologie III der Universität Freiburg, Schänzlestrasse 1, D-78 Freiburg i. Br., FRG

The nucleotide sequence of ribosomal DNA coding for 16*S rRNA from* Zea mays *chloroplast has been determined. A comparison with the* 16*S rRNA sequence from* Escherichia coli *reveals strong homology and thereby demonstrates the prokaryotic nature of chloroplast ribosomes from a higher plant.*

CHLOROPLASTS of green plants contain 70S ribosomes which differ from the eukaryotic 80S type ribosomes of the cytoplasm[1]. The organelle-specific ribosomes mediate translation of organelle-specific mRNAs, which in turn are encoded in chloroplast DNA[2,3]. Organelle-specific rRNA[4] and tRNA[5] species are also encoded in the chloroplast genome, which thus provides the basis for the semiautonomous nature of the organelle. This, along with the various prokaryotic characteristics of the chloroplast-specific translation system, has lent strong support to the endosymbiont hypothesis[6]. This hypothesis postulates that modern chloroplasts are descendants of endosymbiotic prokaryotes—particularly cyanobacteria[7]—which have entered eukaryotic cells during evolution.

Due to a supposedly heavy functional constraint of a highly complex entity such as the ribosome, it seemed likely that its components would have changed comparatively slowly during evolution. Therefore, a comparison of rRNA primary structures from chloroplasts and *E. coli* should provide a quantitative measure of their evolutionary relationship, even if they are separated by a large phylogenetic distance. As an extension of previous work based on T_1-oligonucleotide catalogues[7-9] of 16S rRNAs, complete sequencing should not only allow the exact positioning of conserved T_1 oligonucleotides, but also a comparison of regions in which larger T_1 oligonucleotides are absent. Furthermore, a differentiation between strongly conserved regions and regions which have gone through changes during the course of evolution will be possible only on the basis of complete sequences. We have, therefore, analysed rDNA from *Zea mays* chloroplasts at the nucleotide level, which should allow deduction of the primary structures of the corresponding rRNA species and comparison with the corresponding rRNA species from *E. coli*. Furthermore, it was anticipated that analysis of sequence homology between organelle and *E. coli* rRNA species would support the prediction of secondary structures if they are common or would help to exclude them if they are not preserved. In this article we report the primary structure of 16S rDNA from *Zea mays* chloroplast and compare it with *E. coli* 16S rRNA recently analysed by others[10,11].

Sequencing of maize chloroplast 16S rDNA

DNA from *Zea mays* chloroplasts is a circular molecule of about 135 kilobase pairs on which two rRNA coding regions are positioned in opposite orientation within two 22 kilobase-pair inverted repeats[4]. Each inverted repeat includes within a 12 kilobase-pair *Eco*RI fragment one copy of a 16S rRNA, 23S rRNA, 4.5S and 5S rRNA gene and a 2 kilobase-pair spacer region between the 16S and 23S rRNA genes. One such 12 kilobase-pair fragment has been linked to the plasmid vector pMB9 within the *E. coli* clone pZmc134 (ref. 4). This clone was therefore used for isolation, mapping and sequencing of the 16S rRNA coding DNA fragments, which are positioned within the left half of fragment *Bam*HI·C (Fig. 1)[4,12,13].

In Fig. 2 the RNA-like strand of the entire 16S rRNA gene from maize chloroplast is depicted (lower row of each line). Together with maize chloroplast 4.5S and wheat 5S rDNA sequences (T. Dyer *et al.*, unpublished) it represents—to our knowledge—the first sequence analysis of a complete gene originating from a higher plant.

The exact termini of the structural part of the gene cannot be located by DNA sequencing and must await sequencing of the RNA ends. Taking into account the inhomology of the first four positions, it seems not unlikely that the position of the 5′-terminal nucleotide of maize 16S rRNA is different from position 1, although very close to it. At the opposite end positions 1,540 (last homologous position) or 1,541 (non-homologous, but in accordance with the chain end of *E. coli* 16S rRNA) appear as the most likely candidates coding for the 3′-terminal nucleotide of the chloroplast 16S rRNA. Neglecting this uncertainty a chain length of 1,491 results, which, due to several deletions, is 50 residues shorter than the *E. coli* 16S rRNA.

Sequence homology between maize chloroplast and *E. coli* 16S rRNA

When the maize chloroplast 16S rDNA sequence is compared with the 16S rDNA[10] or rRNA[11] from *E. coli* (Fig. 2) extensive

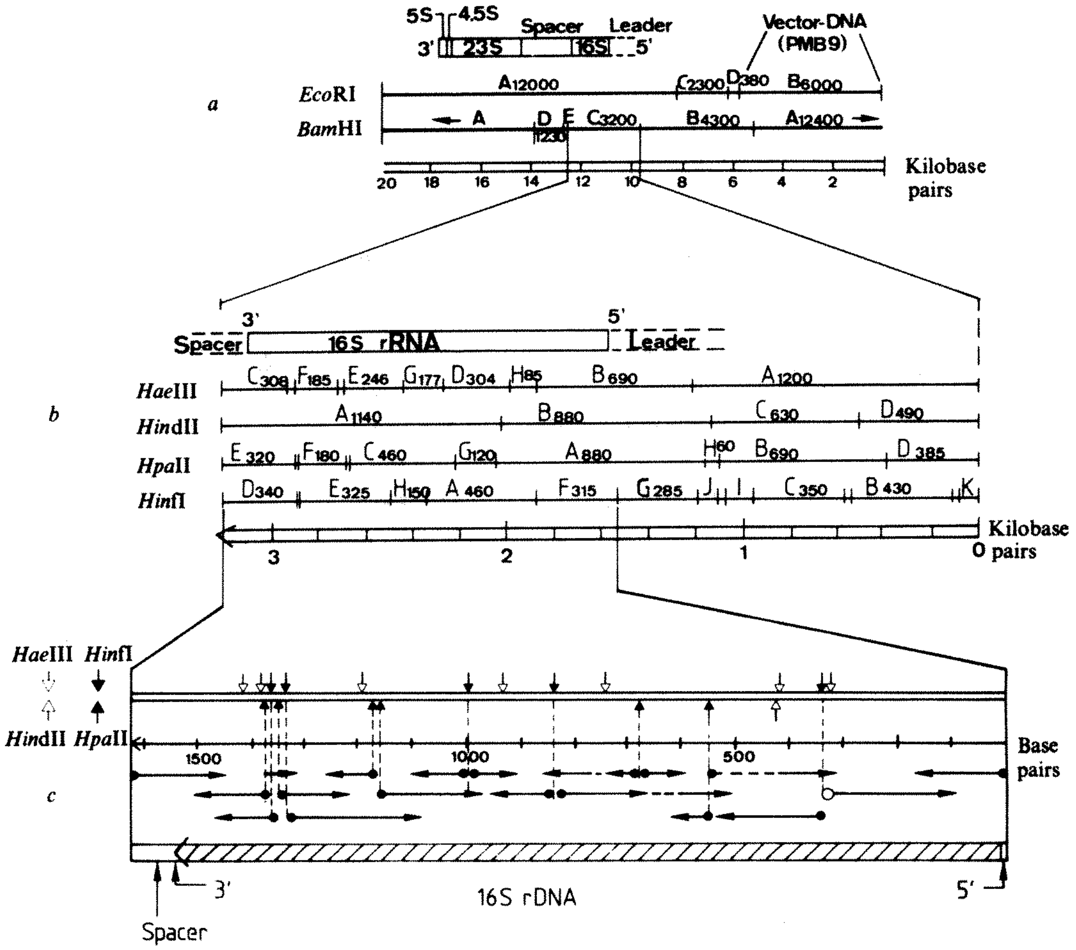

Fig. 1 Physical mapping and use of restriction fragments for sequence analysis of 16S rDNA from *Zea mays* chloroplasts. In *a* the *Eco*RI and *Bam*HI cleavage sites are shown relative to the position of cloned rDNA from maize chloroplasts (fragment *Eco*RI·A) and to the pMB9 vector DNA (fragment *Eco*RI·B)[4,12]. Fragment *Bam*HI·E originally placed between fragment C and B[12,13] has now been positioned between fragments D and C (W. Koch and H. K., unpublished). *b* Represents the fine mapping of fragment *Bam*HI·C, which contains the entire 16S rDNA within its left half. It should be noted that our previous map[12] has been slightly revised in respect to the position of fragments *Hin*fI·F/G and that fragments *Hae*III·C/D have now been assigned by sequence overlaps. In *c* the individual fragment ends selected for terminal labelling and sequence analysis of the respective fragments are indicated by filled circles (5'-terminal labelling) or open circles (3'-terminal labelling). Sequencing was carried out according to the dimethylsulphate/hydrazine procedure[27] with minor modifications as described[28]. The solid part of each connecting arrow represents portions of terminally labelled single fragments from which unambiguous sequences could be obtained. The sequences of most of the fragments have been worked out by a series of overlapping gels (not individually indicated) which allows multiple reading of more than 90% of all positions. The portions of antiparallel overlaps from which sequences for both strands can be deduced can also be seen. Single terminally labelled fragments were obtained from fragments labelled on both ends either by secondary cleavage reactions where sites were available or by strand separation.

homology is observed. Out of the 1,541 residues from *E. coli* 16S rDNA 1,144 positions (74%) are identical in maize 16S rDNA. The maximum number of consecutive identical nucleotides is 53 (positions 916 to 968). Note that in spite of the high degree of homology only less than one third of the cleavage sites for restriction enzymes are identical. Contrary to the structural part of the cistron, an immediately adjacent spacer region comprising nucleotide positions 1,542 to 1,729 shows virtually no homology with its *E. coli* counterpart[13]. Similar divergence has been observed with other spacer sequences[14]. This is evidence for a heavy constraint having acted in favour of the conservation of the ribosomal components during evolution, while an apparently free drift has been possible for the spacer region.

Of the 10 or 11 methylated positions observed in *E. coli* 16S rRNA[10,11] only position 1,206 is not preserved in the maize sequence. All others are identical and embedded within highly homologous regions (Fig. 2). From this a nearly identical methylation pattern can be predicted for chloroplast 16S rRNA if methylation enzymes of equal specificity are preserved in the organelle.

Sequence homology of the two 3'-terminal regions suggests[13] that initiator regions of chloroplast mRNAs will show typical prokaryotic sequences such as GGAGGA and its variants[15,16]. This is supported by the observation that an *in vitro* system from *E. coli* can be used for efficient translation of higher plant chloroplast mRNAs[17,18]. Sequences near the 3' end of *E. coli* 16S rRNA (positions 1,501 to 1,509 and 1,524 to 1,533) have been postulated as being involved in binding of the 50S ribosomal subunit by means of their complementarity to the 3' end of 23S rRNA[19]. This postulate gains support from the observation that these sequences have been largely preserved (except for the two positions 1,507 and 1,526) in maize 16S rRNA. It remains to be seen, however, whether the 3' end of maize 23S rRNA has also preserved complementary sequences and whether complementary substitutions have taken place in the positions corresponding to positions 1,507 and 1,526 of 16S rRNA.

Deletions reduce possible hairpin structures

Due to several deletions the actual chain length of maize chloroplast 16S rRNA is about 50 residues shorter than the *E. coli* species. Apart from several single nucleotide deletions occasionally compensated for by single nucleotide insertions at nearby positions (for example, positions 624/630 or 833/839), three regions containing larger deletions (Fig. 2, positions 77–99, 233–240 and 452–477) are observed within the 5'-terminal third of the cistron. Note that these deleted regions are flanked by conserved regions (with the exception of the left border of the 233–240 deletion) and that due to two of the deletions possible hairpin structures (Fig. 3*a*, *b*) present in *E. coli* 16S rRNA are precisely cut out. Independent evidence for a possible hairpin structure comprising positions 452 to 477 of *E. coli* 16S rRNA (Fig. 3*b*) has recently been deduced from co-migration of oligonucleotides representing this region in a two-dimensional gel electrophoretic system[20]. However, in contrast to Fig. 3*a*, positions 233–240 were predicted to base-pair with positions 122–126. Taking into account that due to the 233–240 deletion one complement of this secondary interaction is completely missing from maize chloroplast 16S rRNA, we consider this possibility unlikely. More likely is a structure in which the base-paired stem of Fig. 3*a* is connected by a continuous stack to a base-paired region comprising positions 241–294 (see Fig. 6 of ref. 20). A further possible hairpin structure is only reduced in size due to two closely positioned deletions (Fig. 3*c*).

It will be interesting to see whether similar deletions are present in other chloroplast 16S rRNAs and if the resulting, apparently more primitive structures are accompanied by smaller sizes of other ribosomal components or by even smaller numbers of ribosomal proteins. (The recent observation of an intervening sequence in the *Chlamydomonas* 23S rRNA gene[21] does not necessarily contradict a more primitive nature of chloroplast rRNA genes, if intervening sequences are interpreted as evolutionary remnants.)

Possible common secondary structures contain compensating base changes

Computer-aided screening of the maize chloroplast 16S rRNA for possible hairpin structures leads to a very large number of hypothetical secondary structures which are difficult to evaluate *per se*. Considering, however, the *E. coli* 16S rRNA species as a not too distantly related mutant species (or vice versa), screening for secondary structures can be narrowed down to structures which are common to both species. Also, common secondary structures gain even higher probability if compensatory base changes are observed in distant positions of the primary structure as exemplified in Fig. 4.

Library SCIENCE COLLEGE 92 Upper Circular Road Calcutta

A loop structure near the 5′ terminus has been postulated for *E. coli* 16S rRNA[22]. The homologous structure of maize chloroplast 16S rRNA shown in Fig. 4*a* contains six base exchanges (as well as one deletion and one insertion, which are considered as neutral) which match each other to allow a loop structure of almost identical size and stability as in the *E. coli* species. We have recently described similar conservation of a 3′-terminal loop structure[13]. In Fig. 4*b* a double loop structure from the middle portion of 16S rRNA is proposed which also includes a far distance pairing between positions 580–587 and 878–884. This domain would contain altogether 11 exchanges of complete base pairs, that is 22 single base substitutions; although the individual exchanges have occurred at comparatively distant positions of the primary structure, they exactly compensate each other and thereby permit maintenance of a thermodynamically highly stable secondary structure of similar size. Such compensatory base exchanges, therefore, give strong support to the functional significance of the proposed secondary structures, although they would have to be confirmed by more direct experimental evidence. Additional support for the existence of the double hairpin region shown in Fig. 4*b* comes from kethoxal reaction data[23], which indicate sensitivity of the G residue at position 790, and from T_1 RNase sensitivity data[24], which show that the two loop regions are sensitive within the free 30S particle. A reduced sensitivity against kethoxal and T_1 RNase in the presence of coupled 50S particles has led to the prediction[23,24] that this domain is involved in the interaction of the 30S and 50S subunits at their interphase. In agreement to this, 30S particles modified at position 790 are not found within the 70S particles obtained from subsequent coupling[25]. From the present data it seems likely that the subunit interaction is mediated by the 768–884 domain of 16S rRNA in the form of

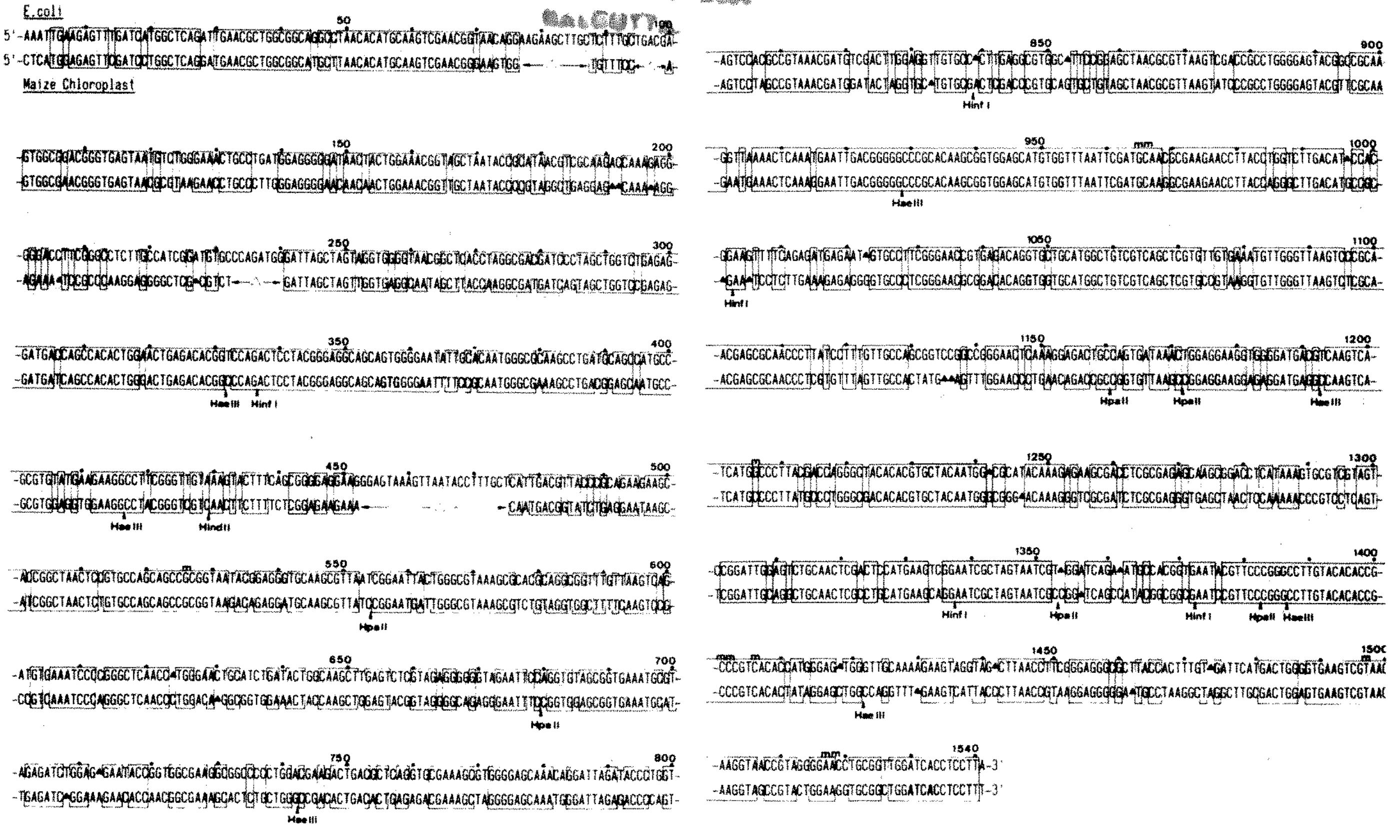

Fig. 2 Nucleotide sequence of 16S rDNA from *Zea mays* chloroplasts. Only the non-coding, RNA-like strand is given in the lower row of each line. The RNA-like strand of *E. coli* 16S rDNA[10,11] is depicted on top of it for comparison. Homologous sequences are marked by boxes. Triangles within sequences symbolise deleted positions as compared to the other DNA. Numbering refers to *E. coli* 16S rDNA. Due to several deletions not all *E. coli* positions are represented in the maize sequence. The actual numbering of the maize rDNA sequences would therefore be correspondingly lower if this sequence would be counted continuously. It should also be noted that the maize chloroplast rDNA sequence is depicted in opposite orientation as compared to Fig. 1. Cleavage sites for the restriction enzymes used in Fig. 1 are indicated. Methylated positions of *E. coli* 16S rRNA are marked by m.

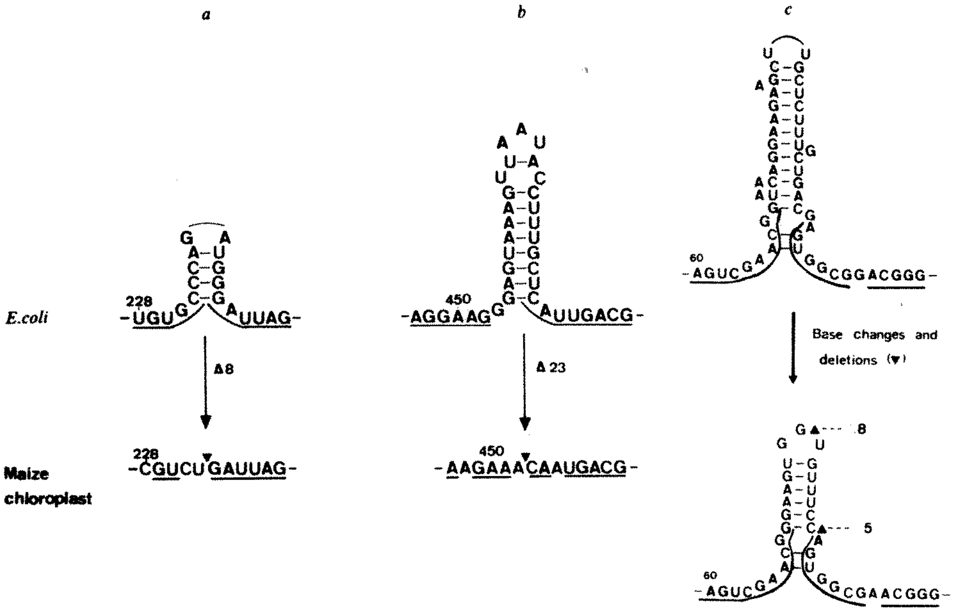

Fig. 3 Postulated hairpin structures deleted (*a*, *b*) or reduced (*c*) in maize chloroplast 16S rRNA as compared to *E. coli* 16S rRNA. Numbers refer to positions in *E. coli* 16S rRNA (see Fig. 2). Homologous positions are marked by underlining. Positions of deletions are indicated by ▼.

the hairpin structures depicted in Fig. 4*b*. Co-migration of oligonucleotides in a two-dimensional electrophoretic system also supports the existence of secondary structure in the 808–997 region of isolated *E. coli* 16S rRNA[20]. From these data, however, a secondary structure very different from Fig. 4*b* was proposed (see Fig. 6 of ref. 20). On the basis of best fit for compensatory base exchanges between *E. coli* and maize chloroplast 16S rRNA we prefer the structure proposed in Fig. 4*b*.

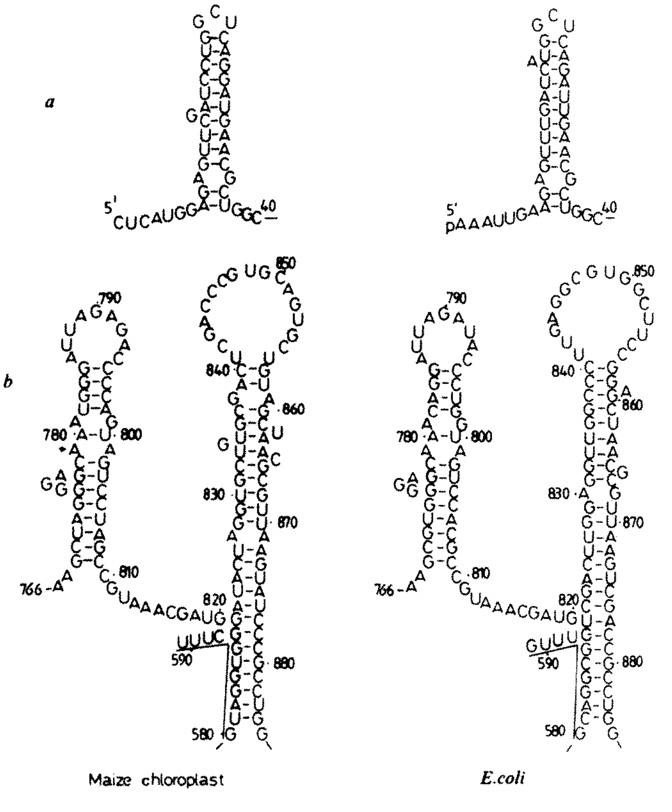

Fig. 4 Postulated secondary structures of 16S rRNA regions which, due to homology and/or compensating substitutions in distant positions of the two chains, show nearly identical dimensions. The two structures to the left represent maize chloroplast rRNA sequences. A possible far distance interaction in *b* is marked by underlining. Numbers refer to positions of *E. coli* 16S rRNA (see Fig. 2).

Compensatory base exchanges also support the proposed secondary structures for the protein S8/S15/16S rRNA interacting site[26] and allow a slight refinement of one of the two proposed structures (not shown here, but compare Fig. 7 of ref. 26 with our Fig. 2).

These examples taken together demonstrate that compensating base substitution between functionally related RNA species can provide a valuable criterion for the evaluation of their hypothetically or experimentally deduced secondary structures.

We thank Dr J. Bedbrook for kindly providing us with the clone pZmc134, Dr J. Gross for computer programing, Mrs E. Schiefermayr for technical assistance and Drs K. Edwards, R. Hausmann and R. Hertel for helpful criticism of the manuscript. This work was supported by grants from the Deutsche Forschungsgemeinschaft (SFB 46) to H.K.

Note added in proof: A major portion of the yeast 18S rDNA has recently been sequenced[29]. A comparison of this sequence with 16S rDNA from either *E. coli* or maize shows only very few homologous regions; this indicates a wide evolutionary distance between prokaryotic 16S and eukaryotic 18S rRNA and further substantiates the prokaryotic character of the maize 16S rDNA.

Left-handed DNA helices

Struther Arnott, Rengaswami Chandrasekaran, D. L. Birdsall, A. G. W. Leslie*
& R. L. Ratliff†
Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907

The synthetic DNA polymer poly d(GC) · poly d(GC) has been studied by X-ray diffraction of orientated fibres in which it has either the well known (A or B) right-handed conformations or a new left-handed helical conformation. Similar left-handed conformations have been observed with poly d(AC) · poly d(GT) and with poly $d(As^4T)$ · *poly* $d(As^4T)$, *demonstrating that the novel structure is accessible to any DNA segment with an alternating purine–pyrimidine base sequence.*

SINGLE crystals of $d(CpG(pCpG)_2)$ complexed with spermine and of the high salt form[1] of d(CpGpCpG) contain duplex structures which, if elaborated in a polymer, would lead to a left-handed DNA double helix of pitch ~4.4 nm containing six dinucleotide pairs (A. Rich and R. E. Dickerson, personal communications). Using X-ray diffraction of oriented fibres, we have been studying the structures of sodium salts of poly d(GC) · poly d(GC), a synthetic DNA polymer of high molecular weight ($\sim 2\times 10^6$). The polynucleotide is usually found to have one of the common (A or B) right-handed double helical conformations. Occasionally it is found with what must be essentially the same left-handed double helical conformation observed in the single crystal studies: its unit of structure is a dinucleotide, its screw symmetry is 6-fold, and its pitch is 4.35 nm. Moreover, our polymer models which incorporate the same *syn*-G and *anti*-C nucleoside conformations observed by the MIT group give a good account of the fibre diffraction intensities (F. J. Kolpac, A. Rich and G. J. Quigley, personal communications).

The left-handed helices can appear in fibres of poly d(GC) · poly d(GC) in which previously the right-handed B-DNA conformation was observed, and in conditions quite unexceptional with respect to hydration or the type or number of associated cations. Similar structures are observed with polymers containing other alternating purine–pyrimidine base sequences. It would be surprising, therefore, if this novel DNA conformation were not used biologically.

Molecular dimensions and packings

The A form of poly d(GC) · poly d(GC) (Fig. 1*a*) is not detectably different from that of other DNAs (ref. 2) being an 11_1 helix of pitch 2.82 nm packing in a monoclinic (*C2*) unit cell with $a = 2.22$ nm, $b = 4.06$ nm, $c = 2.82$ nm, $\beta = 97°$.

The B form (Fig. 1*b*) has the same symmetry (10_1) and helix pitch (3.35 nm) as in other DNAs (ref. 3). The overall intensity distribution in the diffraction pattern also suggests that the normal B-DNA conformation is unchanged although the orthorhombic unit cell with $a = 3.61$ nm, $b = 3.79$ nm, $c = 3.35$ nm probably contains twice as many DNA chains as the usual cell.

The new form (Fig. 1*c*) at 44% relative humidity is a 6-fold helix which packs in a hexagonal unit cell with $a = b = 1.91$ nm, $c = 4.35$ nm. The axial translation per (dinucleotide) residue is therefore $h = 0.725$ nm.

The conformation of left-handed DNA

The structures of about two dozen right-handed polynucleotide helices have been examined in detail[4]. All of them are conformationally polymononucleotides. The novel form of poly d(GC) · poly d(GC) is a polydinucleotide conformationally as well as chemically. Using the linked-atom least-squares procedure[5,6] and assuming that the G and C nucleosides have *syn* and *anti* conformations respectively (as found by the MIT group), we have produced a preliminary model for this structure (Table 1 and Figs 2 and 3) with standard bond lengths and bond angles and a minimum of steric compression. One nucleotide (pC) has the same kind of conformations that are commonly observed in right-handed polynucleotide helices such as A- and B-DNA. The nucleotide pG is quite different not only in the mutual orientation of sugar and base rings but also in the C4′–C5′ conformation which is *trans* rather than *gauche*$^+$, and the P–O conformations which are *gauche*$^+$ rather than *trans* or *gauche*$^-$. Nevertheless, this combination of conformation angles yields a structure free of overshort nonbonded contacts.

Morphology

In a polymononucleotide duplex every nucleotide is quasi-symmetrically related to every other one by the operations of the molecular screw axis or the dyad axes in the mean plane of each base pair and midway between each pair. One consequence is that the normals to every base plane make equal angles (γ) to the helix axis. In a polydinucleotide duplex like the novel left-handed DNA this is no longer the case and the guanines ($\gamma_G = 18°$) have quite a different orientation to the cytosines ($\gamma_C = 7°$).

The angle between the guanine and cytosine planes of a base pair (14°) is similar to that found in A-DNA (10°) and B-DNA (13°). The twist axis is tilted 5° from being perpendicular to the helix axis. This tilt is in the same sense as in all members of the B genus of polynucleotide helices[4]. The position of the base pairs relatively close to the helix axis is also like that found in the B genus. Consequently both major and minor grooves are deep. The base pairs are well stacked. As is commonly the case in polynucleotide duplexes most of the overlap involves the central part of the base pairs and not overlap of the heterocyclic rings themselves (Fig. 2). The cytosines are sandwiched relatively effectively between the guanines but these are more exposed.

Another consequence of the molecular asymmetric unit being a dinucleotide is that successive phosphate groups do not have the same radius (R): in CpG $R_P = 0.95$ nm; in GpC $R_P = 0.85$ nm. Nor are the phosphates equally spaced along the polynucleotide chain: in pGp $d(P\ldots P) = 0.61$ nm, in pCp $d(P\ldots P) = 0.64$ nm. As a result of this, pairs of proximate phosphates from the antiparallel chains cluster together (Fig. 3). Effective charge neutralisation or shielding is thus important to maintain this structure.

The provenance of the left-handed form of poly d(GC) · poly d(GC)

It is well known[10,12] that an unusual structure is accessible to poly d(GC) · poly d(GC) and its fragments in aqueous solutions of higher concentration than 2.5 M in Na^+ or >0.7 M in Mg^{2+}. The predictions of Patel *et al.*[10] with regard to the details of this unusual structure are sufficiently fulfilled by our model for

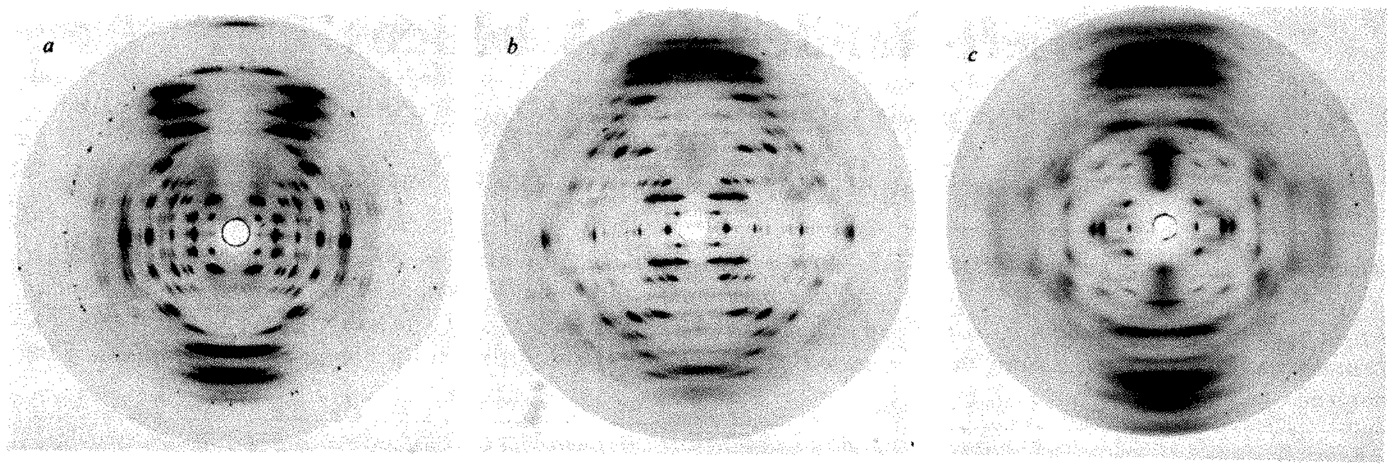

Fig. 1 X-ray diffraction patterns from oriented fibres of poly d(GC) · poly d(GC) in its A form (*a*), B form (*b*) and novel form (*c*). The specimens containing the A and B forms are also polycrystalline so that only Bragg reflections are observed. The symmetry of the new conformation is 226_5 and the space group of the diffracting structure probably $P226_5$. Which of the two molecular dyad axes (separated by $c/12$) is made to coincide with a space group dyad appears to be indeterminate. The result is a 'statistical' crystal structure[13] which gives both Bragg reflections and continuous streaks. The former are predicted to prevail on layer lines 0,2,5,7,9,14 the latter on layer lines 1,6,8,11,13 as observed.

us to be in no doubt that the new structure trapped in our oriented fibres is essentially the one that has been probed spectroscopically in 'high salt' solutions. The circumstances in which we have observed the transition to this new form in fibres supports this conclusion. It appears after prolonged annealing in some fibres prepared with the 3–6% retained NaCl necessary to reproduce the B conformation in typical DNA specimens. The left-handed helix has never appeared in fibres with minimum retained salt. With these, the A-DNA structure is observed initially and persists even after annealing for 30 months.

Apparently, left-handed helical conformations are not confined to poly d(GC) · poly d(GC) but are accessible certainly to other DNAs with alternating purine–pyrimidine nucleotide sequences. We have observed a similar diffraction pattern with one poly d(GT) · poly d(AC) specimen. This implies that pA can, when necessary, mimic the novel pG conformation. This conclusion is reinforced by the structure of poly d(As^{4}T) · poly d(As^{4}T). These molecules can have 7-fold screw symmetry[11] and pack in quasihexagonal unit cells with $a = b = 1.8$–2.3 nm and $c = 5.3$–5.4 nm depending on the relative humidity.

Although Saenger *et al.* interpreted the structure of poly d(As^{4}T) · poly d(As^{4}T) quite differently, we think that the diffraction patterns are so similar to Fig. 1*c* that a left-handed structure (Table 1) with $h = 0.76$ nm, $t = -51.4°$ (rather than 0.73 nm and −60°) provides a more plausible solution. Although s^{4}T nucleosides have been observed with the *syn* conformation in crystals[14,15], our modelling suggests that it is the purine (A) and not the pyrimidine (s^{4}T) nucleosides which play the conformationally unorthodox role like G nucleosides in the left-handed helix.

We have tested the possibility that our left-handed structure is accessible to DNAs with other base sequences by exchanging C and G and by imposing the homopolymer sequences of poly d(G) · poly d(C) on our model. Considerable steric compression results in both cases. Left-handed helical secondary structures that would accommodate any nucleotide sequence, therefore, would have to be somewhat different in conformational details.

Table 1 Comparison of conformation angles in the two common right-handed DNA helices with those of two left-handed helices

Under each helix type are given the molecular screw symmetry and axial rise per asymmetric unit.

* From ref. 7 as adjusted for ref. 8.

† The C2′-*endo* model of ref. 9 re-refined by S.A. and R.C. (unpublished data).

‡ It is too early to claim that these are the only conformations consistent with the diffraction from poly d(GC) · poly d(GC) but they are similar to those of the core of d(CpG(pCpG)$_2$) in one of its crystallised duplex forms (G. J. Quigley, personal communication) and to the structure anticipated by Patel *et al.*[10] from their NMR study of d(CpG(pCpG)$_3$) in solutions of relatively high ionic strength (2.5 M NaCl). Certainly, the diffraction pattern predicted by the model (Figs 2, 3) closely resembles the one observed (Fig. 1*c*): the crystallographic residual for the Bragg reflections has a value $R = 0.27$.

§ This model for the structure of poly d(As^{4}T) · poly d(As^{4}T)[11] may not be the best solution.

DNA polymorphism

The considerable polymorphism of regular helical DNA duplexes has only recently been established. In the A genus, having polymononucleotides with C3′-*endo* furanose rings and all conformation angles of the same kind as A-DNA in Table 1, there is little variability in the rotation per nucleotide residue ($30° \leq t \leq 33°$) except for single-stranded molecules when $t = 60°$ is possible[16]. However the translation per residue (and therefore the mass per unit length) can vary by as much as 23% ($0.26\ \text{nm} \leq h \leq 0.33$) from A-DNA to poly d(T) · poly d(A) · poly d(T). In the B genus—polymononucleotides with C2′-*endo* furanose rings and all conformation angles as in B-DNA in Table 1—h is not quite so variable ($0.30 \leq h \leq 0.34$ nm) but t varies from its low value of 36° in B-DNA to its high value of 45° in D-DNA[17].

The discovery of a left-handed DNA conformation dramatically extends the range of secondary structures known to be allowed to DNA duplexes and may help to render moot many topological problems thought to be associated with some DNA activities. The known DNA conformations that are substantially overwound or underwound compared with B-DNA could be used to store or shunt locally the rotations needed to wind or unwind a double helix. For example, a segment of left-handed DNA, maintained in a region where the preferred sequences were sufficiently common, could be a store of negative windings. In appropriate conditions these could be used to compensate positive windings and produce a region of melted DNA available for polynucleotide synthesis. Conversely, regions of unwound DNA could condense to give contiguous segments of left-handed and right-handed helical DNA separated by as few as two nucleotides[18]. Such a structure might be a manageable substrate for topological isomerisation. Alternatively, the left-handed segment would form a package of negative windings which could be translocated easily even to a distant site.

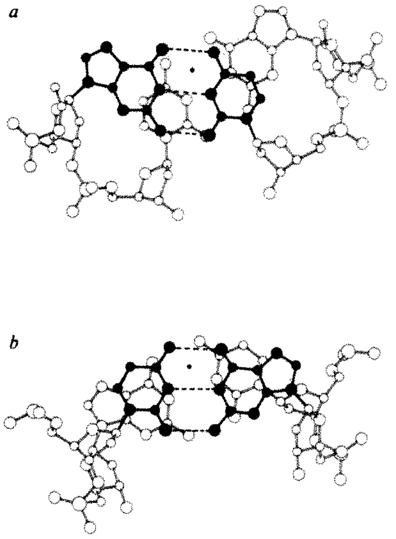

Fig. 2 The base stacking of *a*, GpC and *b*, CpG. The helix axis position is shown by a dot. A molecular dyad axis exists midway between the base pairs in each stack shown. In contrast to the more familiar polymononucleotide structures, the local dyad axis relating the glycosidic links of a base pair does not intersect the helix axis.

Overwound and underwound DNA secondary structures could also be associated with the creation or maintenance of supercoiled tertiary structures of either hand. When these are formed or destroyed, compensating changes in secondary structure are required. What these secondary structures might be has now been visualised.

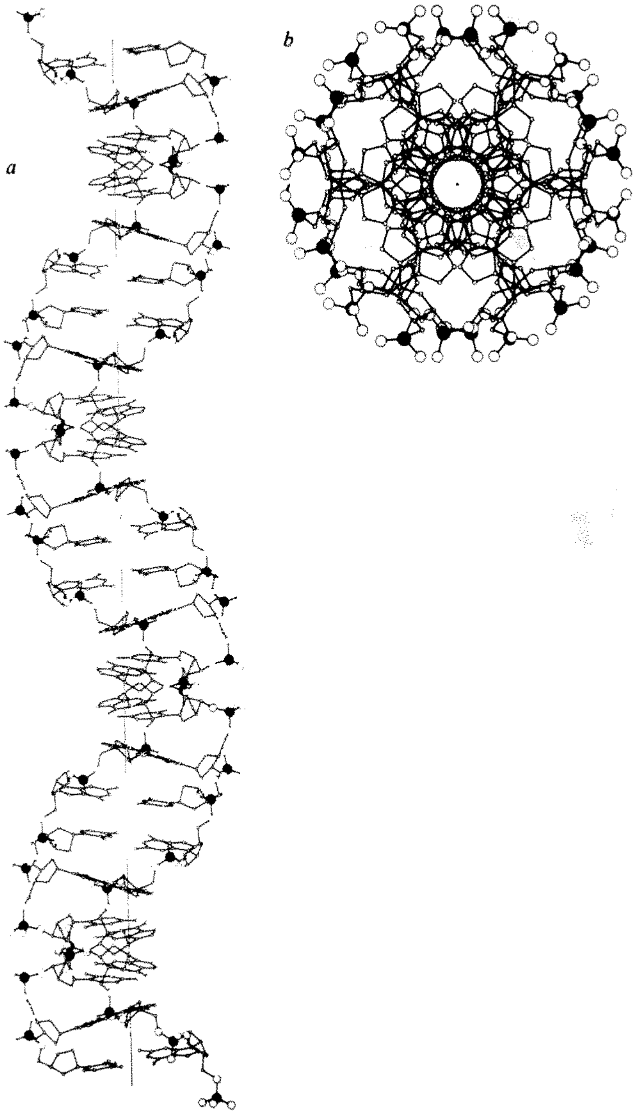

Fig. 3 A two-pitch length fragment of the new form of poly d(GC) · poly d(GC) viewed perpendicular to (*a*) and along (*b*) the helix axis and showing the disposition of the phosphate groups whose atoms are depicted with large circles.

We thank Alexander Rich and his colleagues, whose data has since been published[19], and R. E. Dickerson for discussing some of their results before publication, Bill Boyle for photography and the US PHS for support (grant GM17371 to S.A.).

LETTERS

Is 0406 + 121 the reddest BL Lac object?

Marc Aaronson & Todd Boroson

Steward Observatory, University of Arizona, Tucson, Arizona 85721

0406 + 121 is a flat-spectrum variable radio source first discovered by Shimmins *et al.*[1] and later studied by Condon *et al.*[2]. While no optical counterpart was identified, similar sources were often found to be either BL Lac-type objects or high redshift QSOs. Recently, Rieke *et al.* detected the object in the near-IR, where it was observed to vary in luminosity over the six-month period between August 1978 and March 1979. A Kitt Peak 4-m plate taken on 29 November 1978 and published by Rieke *et al.* revealed a stellar image ($V = 20.5 \pm 0.4$ mag) at the radio (and IR) position, which lies ~30 arc s north of an anonymous spiral galaxy. Rieke *et al.* suggested that 0406 + 121 and some similar sources they detected having steep power law spectra were a possible new type of QSO discriminated against in conventional optical searches. To clarify the nature of 0406 + 121 further, we obtained a spectrum in good seeing conditions on the night of 27 February 1979 using the Steward Observatory 2.25-m telescope and intensified Reticon spectrograph. The object, clearly visible on an intensified TV guider, was wobbled every 80 s between two circular apertures 2.5 arc s in diameter spaced 20 arc s apart. Eighty-five minutes of integration time, calibration with the spectroscopic standard EG 67 (ref. 4) and a HeAr comparison lamp, and eight point smoothing of the 10 A resolution spectrum gave the results shown in Fig. 1.

The spectrum in Fig. 1 is consistent with a smoothly rising featureless continuum and seems to place 0406 + 121 in the class of BL Lac-type objects. However, the source is unusual in several respects. First, a $\nu^{-\alpha}$ power law fit to the data leads to $\alpha \approx 3.8$. The absorption implied at galactic latitude $b = 28°$ is $A_V \approx 0.11$ mag (ref. 5) so that corrected for reddening, $\alpha \approx 3.7$, to which we attach a conservative error of ±0.7. Taken at face value, the optical continuum of 0406 + 121 is thus the reddest known for any object in the BL Lac class. For comparison, α is ≈ 3.2 for AO0235 + 164 and ≈ 3.1 for BL Lac itself, the sources having the steepest previously known spectra[6].

A second curious property of 0406 + 121 concerns the possible lack of optical variability as compared with that seen in the near-IR. The V flux we derive from Fig. 1 is 20.2 ± 0.3 mag. This agrees closely with the photographic V magnitude measured three months earlier and quoted above. (A further check on this consistency was provided by our own visual estimate off the TV guider!) However, a systematic and substantial decrease in near-IR brightness was observed by Rieke *et al.*: they measured a K (2 μm) flux of ≈ 14.0 mag at the end of August 1978; a flux of ≈ 14.3 mag on 11 September 1978; a flux of ≈ 14.9 mag on 10 February 1979; and could not detect the object on 8 March 1979 (nine days after our spectrum was taken) when a 2 σ upper limit of ≈ 15.6 mag was obtained.

We have examined all of the published IR photometry of BL Lac sources compiled in Table 1 of Rieke and Lebofsky[7]. In every other instance when luminosity variations are observed, either the optical and near-IR flux change in step, or the optical flux changes over more rapid time scales. In particular, during periods of fading, the optical luminosity has been observed to decrease faster than in the near-IR in AO0235 + 164 (ref. 8) and in B21308 + 326 (ref. 9). If we interpret the Rieke *et al.* 2-μm observations as indicating a gradual and constant decline, then the optical and near-IR continua of 0406 + 121 are decoupled in a manner that is very atypical. This may have important implications in regard to the underlying source energetics (see ref. 10).

Unfortunately, neither of the V magnitudes (which are themselves more uncertain than desirable) were determined simultaneously with the IR data. Thus we cannot rule out the possibility, however unlikely, that our spectrum was taken during an outburst of 0406 + 121 (a common event for BL Lac objects) which then faded rapidly, giving the appearance of constant optical luminosity.

Weak evidence for at least some change in the optical flux of 0406 + 121 over the past 30 years is provided by the absence of the object on either the blue or red Palomar Observatory Sky Survey (POSS); for example, the present brightness above the red POSS plate limit is ≥ 0.5 mag.

In one respect 0406 + 121 does seem similar to its cousins AO0235 + 164 and BL Lac in that the near-IR spectral index seems less steep than in the optical. Physical reasons for such an effect have been considered by O'Dell *et al.*[8]. While again lack of simultaneously obtained data does not permit a conclusive decision, two indirect arguments do suggest the presence of a

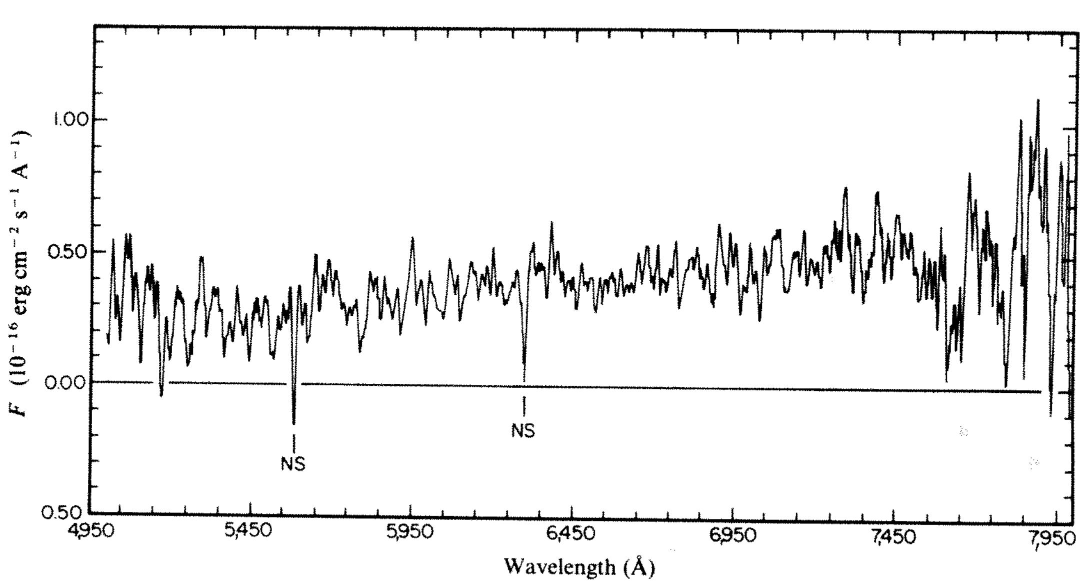

Fig. 1 A spectrum of 0406 + 121 is shown. Only a smoothly rising continuum is apparent, except for two poorly subtracted night sky lines. The spectrum becomes rather degraded shortward of 5,300 Å and longwards of 7,400 Å.

0028-0836/80/080746—02$01.00

spectral inflection point. First, the IR data of Rieke *et al.* are consistent with $\alpha \approx 2$–2.5, as compared with 3.7 here. Second, if our spectrum is extrapolated, then the predicted K flux is ≈ 10 times greater than a plausible interpolation of the 10 February and 8 March IR measurements. Any outburst this strong on such a short time scale would be unparalleled.

Clearly, further monitoring is essential to establish whether 0406 + 121 and similar objects are simply extreme cases of more familiar sources or represent a truly unique category.

We thank G. Rieke and M. Lebofsky for valuable discussions, and R. Moore for assistance at the telescope. This work was partly supported with funds from NSF grants AST 76-81874, AST 76-22991, and AST 79-21663.

A dramatic radio outburst in the quasar 1921 – 29

William A. Dent & Thomas J. Balonek

Department of Physics and Astronomy, University of Massachusetts, Amherst, Massachusetts 01002

We report here an exceedingly large amplitude radio outburst presently occurring in the quasi-stellar source 1921 – 29 (also known as OV – 236). This source which had exhibited slow ±25% variations about a 6 Jy level (1 Jy = 10^{-26} W m^{-2} Hz^{-1}) at centimetre wavelengths since 1971 has suddenly increased by more than a factor of 3 to 20 Jy. At 31 GHz, 1921 – 29 is now the strongest known quasar in the sky, even exceeding 3C273 which has been decreasing since 1975.

Variation curves at four radio frequencies from 1971 to the present are shown in Fig. 1. These observations of 1921 – 29 are part of our study of the long-term spectral evolution of variable radio sources. The measurements at 89.6 and 31.4 GHz were made with the 36-foot antenna of the National Radio Astronomy Observatory[1,2] and those at 15.5 and 7.9 GHz were made using the 120-foot antenna of the Haystack Radio Observatory[3,4]. The sharp rise in flux density begins at 89.6 GHz near 1979.3 and is progressively delayed at lower frequencies. Radio spectra of the source at four different epochs are shown in Fig. 2. The spectral turnover below 15 GHz at 1979.5 and 1979.8 is characteristic of self-absorption in a source emitting synchrotron radiation. The broad spectral maxima imply an inhomogeneous distribution of radiating particles and magnetic field.

The recent outburst is itself superimposed on a more slowly varying component which increased gradually through 1976 and 1977 and then remained constant until early 1979. Its broad flat spectrum in Fig. 2 is also characteristic of a self-absorbed inhomogeneous source. The high frequency transparent portion of the spectrum has a slope of $\alpha \approx -0.4$ above 31 GHz. Like the current 1979 outburst, the rise during 1977 of this slow component was self-absorbed and delayed at lower frequencies.

The spectrum of the rapid 1979 outburst at different epochs can be obtained (Fig. 3) by subtracting the spectrum of the source in 1978, just before the recent outburst. We see that the outburst itself has an initially steep low frequency cut-off with spectral index $\alpha \approx +2$ below 15 GHz. As the outburst evolves its low frequency spectrum flattens as the frequency of maximum decreases from about 100 to 30 GHz. The high frequency spectrum above 31 GHz becomes transparent with $\alpha \approx -0.3$, implying $\gamma = 1 - 2\alpha = 1.6$ in a relativistic electron distribution of the form $N(E)\,dE \propto E^{-\gamma}\,dE$. Such a hard electron distribution is characteristic of most variable radio sources. This distribution seems to be preserved over the different phase of activity in the source demonstrating the consistency of the particle acceleration mechanism.

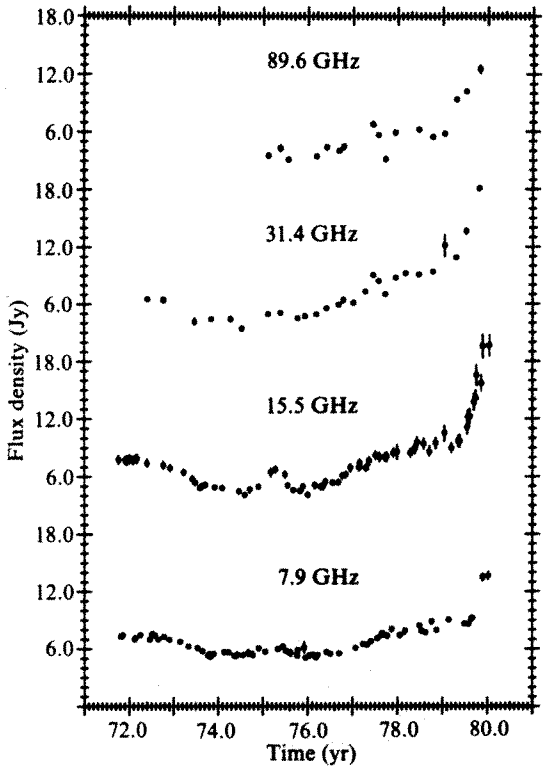

Fig. 1 The observed variation of 1921 – 29 at four radio frequencies.

The spectral evolution of both the slow 1977 outburst and the rapid 1979 outburst suggest that both are expanding from an initially smaller volume[5]. The initially sharp and eventually broad low frequency turnover of the slow outburst shows that an initially homogeneous component became inhomogeneous as it expanded. The pronounced difference in time scales of the two events must be due either to different rates of expansion or to time compression if there is relativistic motion near the line of sight.

Even though it does not have a published redshift, 1921 – 29 is undoubtedly a quasar. It has been identified as a stellar object

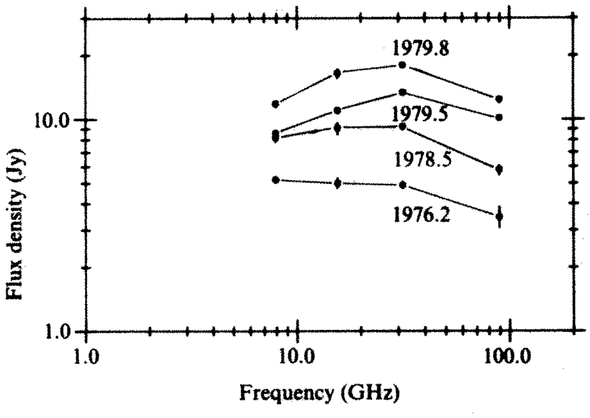

Fig. 2 The total radio spectrum of 1921 – 29 at four epochs.

0028-0836/80/080747—02$01.00

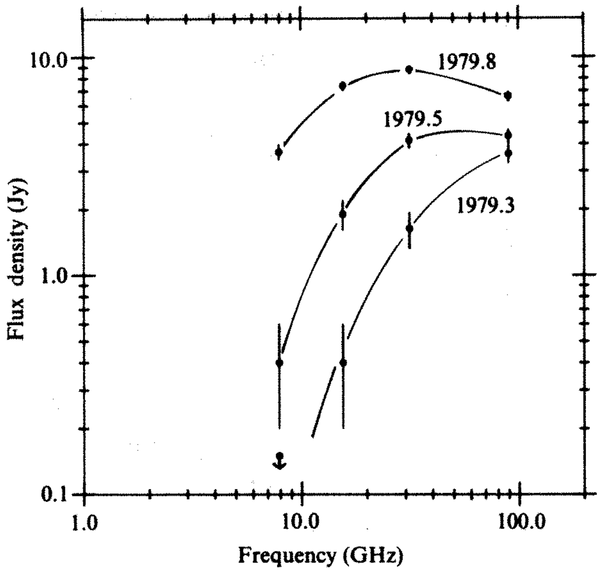

Fig. 3 The spectrum of the 1979 outburst at three epochs obtained by subtracting the average 1978 radio spectrum during 1978.

with a red colour[6] and flat radio spectrum[7]; it is variable at both radio and optical frequencies[8] and has angular structure $<10^{-3}$ arc s at 13 cm (ref. 9). The optical position of this 17 mag quasar is 19 h 21 min 41.42 s and −29°20′25.3″. Optical and X-ray observations of its spectrum and variability during the current outburst would be very valuable.

We thank the staffs of the NEROC Haystack Observatory and the NRAO for their continuing technical support. This research, and the NRAO and Haystack Observatories are supported by grants from the NSF.

Thermal history, chemical composition and relationship of comets to the origin of life

W. M. Irvine*†, S. B. Leschine‡ & F. P. Schloerb*

* Department of Physics and Astronomy, University of Massachusetts, and † Onsala Space Observatory, Chalmers University of Technology, Sweden
‡ Department of Microbiology, University of Massachusetts, Amherst, Massachusetts 01003

It is generally believed that a comet consists basically of a loose conglomeration of frozen gases with embedded material similar to that found in the carbonaceous chondritic meteorites, and consequently that comets may be nearly pristine samples of the original solar nebula[1–5]. We show here that thermal processing within comets could have played an important part in determining their present state; in particular, we find that liquid water might have been available in some comets over geologically and biologically significant spans of time. It follows that a cometary origin is not excluded for some thermally metamorphosed meteorites and asteroids, that comets may contain quite complex organic molecules, and that comets may have played a role in the origin and conceivably even in the subsequent evolution of terrestrial life.

Given a mixture of ices and chondritic material with the normal abundance of radioactive elements (U, Th, and K), Lewis[6] and Whipple and Stefanik[7] have shown that the central temperature in comets will not exceed the melting point of H_2O. Recently, however, inclusions with anomalous isotopic abundances have been found in certain meteorites which suggest that a nearby supernova explosion may have injected significant amounts of the short-lived radionuclide ^{26}Al into the condensing solar nebula[8]. In fact, the necessity for such a short-lived heat source was earlier implied from studies of the mineralogy of meteorites[9,10]. As it seems likely that comets formed in the outer portion of the Solar System, at least some of these objects may have received a particularly large dose of such 'extra-solar' material. An important parameter affecting the subsequent thermal history of a comet is the size of the cometary nucleus. Direct observations are largely non-existent, but present evidence is consistent with a model in which at least some new comets have radii of the order of 10 km (refs 11–14), while occasional cometary nuclei could be an order of magnitude or more larger (the largest presently observable possibly cometary object may be Chiron[15], whose radius is probably ~100 km (E. Bowell, personal communication)).

Will the surface temperature of a comet heated by such short-lived radioactivity be cool enough to retain the volatile material observed? An upper limit to the surface temperature can be obtained by assuming a sufficiently high thermal conductivity that all internally generated heat is immediately radiated away. The abundance of ^{26}Al in the meteoritic inclusions[8,16] is $^{26}\mathrm{Al}/^{27}\mathrm{Al} = {\sim}5\times10^{-5}$, which yields an available heat of 2 kcal g^{-1}. Since the half-life of ^{26}Al is 7×10^5 yr, we find that heat is generated at a rate $Q \simeq 2\times10^{-3}$ erg g^{-1} s^{-1}. The corresponding surface temperature T_s for a cometary nucleus of density ρ and radius R is $T_s \leqslant (QR\rho/3\sigma)^{1/4} \leqslant 120$ K for $R \leqslant$ 100 km, $\rho \simeq 2$ g cm^{-3}, and σ = the Stefan–Boltzmann constant. As this is an upper limit and T_s will decrease as the heat source decays, H_2O is certainly retained by the comet[17]; and H_2O may control the vaporisation of more volatile compounds, if these are trapped as clathrates in the H_2O lattice[18].

The temperature is potentially quite different in the interior of a comet. The abundance of ^{26}Al is sufficient to melt silicates, let alone icy material, provided thermal loss to the surface of the body is sufficiently slow[16] and provided (as we here assume) that the formation time of comets is not long compared with the ^{26}Al half life. Thus, even if significantly diluted by material without such short-lived radionuclides, sufficient energy would be available to raise the interior temperature of a comet to several hundred degrees. The time scale t_{int} for cooling the central regions is approximately $t_{\mathrm{int}} \simeq R^2\rho C_p/k = R^2/\kappa$ where k is the thermal conductivity and $\kappa = k/\rho C_p$ is the thermal diffusivity. At $T = 120$ K (appropriate to some intermediate region in the mantle of the comet) the thermal constants for ice are $C_p = 10^7$ and $k = 6\times10^5$ in c.g.s. units[19,20], so that the thermal diffusivity is $\kappa \simeq 3\times10^{-2}$ cm^2 s^{-1} for $\rho \simeq 2$ g cm^{-3}. For a loosely compacted body, however, κ might be significantly lower; for the Moon κ varies from $\simeq10^{-4}$ cm^2 s^{-1} near the surface to $\simeq10^{-3}$ cm^2 s^{-1} in the deeper regolith[21,22]. Counteracting the latter effect might be the possibility of thermal transport by gaseous diffusion and convection. If we take the intermediate value $\kappa = 0.004$ cm^2 s^{-1}, we find $t_{\mathrm{int}} \simeq 10^9$ yr for $R = 100$ km. For the more typical radius 10 km for a new comet, we find a cooling time for the interior of the order of 10^7 yr. These times might in fact be significantly lengthened by the accretion of an insulating dust layer, as Wood has proposed for the parent planetesimals of certain meteorite classes[23].

Note the following astronomical consequences. Some comets may have undergone significant thermal processing, so that the apparent exposure of, for example, chondritic meteorites and probably some Apollo asteroids to temperatures of several hundred degrees[24] does not in itself exclude their being derived from comets. Such an origin has been supported on dynamical[25] and spectroscopic[26] grounds, although other problems remain[27]. (If, instead of being initially homogeneous, comets were formed by accretion of volatiles onto an asteroid core[28,29], a similar generic relationship could exist.) Likewise, the existence in new comets of a particularly volatile outer shell, suggested by the appearance of a gaseous coma at large distances from the Sun[30], is a natural consequence, although this does not require as strong a heat source as considered here[7]. The possibility of thermal processing must be considered in calculating the chemical composition of the cometary volatiles. The original composition of the nucleus, like that of the Sun and the interstellar medium, will be reducing. Heating such a mixture, particularly in the presence of the metallic and clay catalysts expected to be present, results in the production of organic molecules, including amino acids and nucleic acid bases[31–33]. Complex organic molecules are also produced in such mixtures by ionising radiation, which would result from the radioactive decay postulated here[34].

Could comets be relevant to the origin of life? A principal problem in the synthesis of biologically significant molecules in the aqueous terrestrial environment is the polymerisation of amino acids and nucleic acid monomers. Dehydration reactions involving volcanic heating and/or evaporation and catalysis in tidal pools have been invoked[32,35]. Suitable environments might more naturally occur in a comet, where we may suppose temperature regimes from considerably above the boiling point of H_2O to a perhaps substantially depressed (by dissolved salts) freezing point, solid clay and metallic surfaces for catalysis, possible circulation of an aqueous solution with dissolved organics, and much less dilution than would be expected in a terrestrial ocean. Moreover, the time span determined above during which liquid water might be available in some comets is consistent with geochemical evidence for the epoch of the first O_2-releasing photosynthesis on Earth[36]. The biological requirement for free energy in a dark environment has been considered by Anders[37] in a discussion, similar to the above, concerning the possibility that asteroids might have supported life (we note also the existence of apparently photosynthesis-independent biocommunities at mid-ocean thermal vents[38]). Present models postulate that the Sun is surrounded by a vast cloud containing perhaps 10^{11}–10^{12} comets[39] and thus providing environments for a vast number of 'biological experiments'. When a comet enters the inner Solar System, it leaves behind a trail of debris which is encountered by the Earth as meteor showers and micrometeoroids. The Earth accretes about 10^7 kg yr^{-1} of such material[5,40]. Micrometeoroids smaller than 10^{-6} g will not be heated above 100 °C on entry, and the interiors of meteorite-sized objects also remain at moderate temperatures[41,42]. It follows that comets may have played a part in seeding the primitive Earth with biological polymers possibly capable of self-replication, or at least of evolving towards that capability.

Is it conceivable, as suggested by Hoyle and Wickramasinghe[43,44], that in subsequent times the Earth has been infected by organic material which arose independently in cometary environments and which was viable in terrestrial organisms? The resemblance between the genetic systems of viruses and cells implies that the evolution of viruses depends on the evolution of cellular genetic systems[45] and therefore makes the independent evolution of viruses on many different comets very unlikely. On the other hand, it seems difficult to exclude the possibility that small nucleic acids of cometary origin might occasionally be viable in terrestrial organisms if (in the apparent manner of viroids[46,47]) they could reproduce without the expression of self-specified proteins, so that they need not have evolved a genetic code translatable by the host cell.

We thank Professors E. Anders and F. Whipple for helpful correspondence and C. Harwood for useful discussions. This research was conducted with partial support from NASA grant NGL 22-010-023.

Neutron holography using Fresnel zone plate encoding

T. D. Beynon & A. G. Pink

Department of Physics, University of Birmingham,
Birmingham B15 2TT, UK

Zone plate shadow casting is a complementary technique to the Leith–Upatnieks modification of Gabor's interferometric method for producing holograms[1,2]. Suggested originally by Mertz[3] in 1961 for use in X-ray astronomy, the technique has received considerable attention in nuclear medicine[4] for imaging radioactive organs via emitted X rays and γ-rays and, more recently, for examining in a tomographic sense the microscopic spatial source distributions of X rays and charged particles in laser-produced plasmas[5]. A series of simple experiments are described here which demonstrate that zone plate encoded neutron holography can be used to image objects. An object placed in a cold neutron beam from a research reactor scatters neutrons through a Fresnel zone plate, with alternate zones of gadolinium and aluminium, which produces a hologram of the object on an X-ray film. The image is constructed by placing the hologram, linearly reduced in size, in a converging laser beam which produces a real image of the original object. Results are presented for two objects, a pair of 0.01 m diameter rubber spheres and a 0.04 m square Maltese cross made from polytetrafluoroethylene (PTFE).

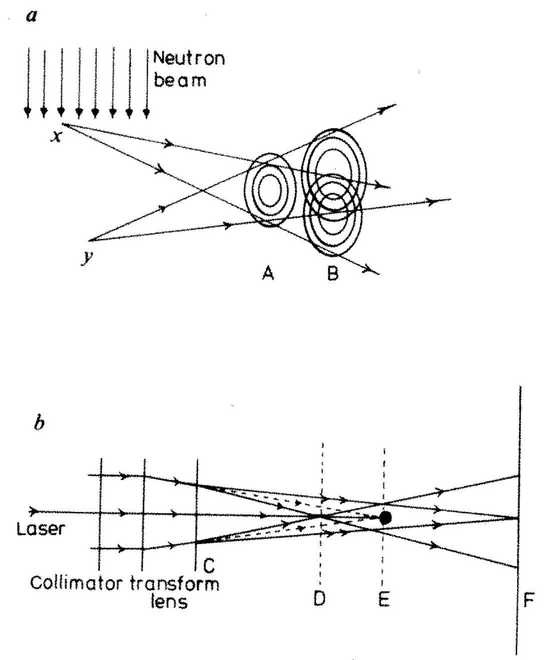

Fig. 1 *a*, Schematic arrangement of two point sources at x and y producing, through a fresnel zone plate at A, a zone plate hologram in a plane at B. The direction of the neutron beam is parallel to the zone plate at A. *b*, The optical arrangement for the reconstruction at E of the object encoded in the hologram at C.

The basic principles of zone plate encoded holography are outlined in Fig. 1. If we consider (Fig. 1*a*) two point sources of radiation at x and y, a Fresnel zone plate at position A will produce in a plane at B two overlapping zone plate shadowgraphs, provided that the wavelength of the radiation from x and y is sufficiently small not to be diffracted by the zone plate. Any solid object, regarded as a linear superposition of points, will produce on a suitable recording material in a plane B a two dimensional hologram consisting of a linear superposition of zone plate shadowgraphs in which is encoded non-coherently the full three dimensional information of the object. The reconstruction of the original object may be achieved coherently by using the optical properties of a Fresnel zone plate, as shown in Fig. 1*b*, which illustrates what is essentially a hardware analogue Fourier transform of the hologram. Each single zone plate in the hologram, acting as a lens, will produce a unique point image of the object point which produced the shadowgraph zone plate. A converging coherent light beam, produced by the transform lens, passes through a linearly reduced transparency of the hologram at a position C. The undiffracted component of the beam is stopped at E. The image at D, due to the negative focal length of the hologram, is superimposed as background on the desired image at E which is due to the hologram's positive focal length. The image in a particular plane through F is the reconstruction of a particular plane in the original object parallel to the original zone plate (Fig. 1*a*). All such object planes may now be retrieved by recording the images on the F-planes spanning the space in which the real image appears.

Neutron holograms have been made for several objects using the 6H beam tube on the DIDO research reactor at AERE, Harwell. This facility provides a well-collimated beam of cold neutrons (energies < 5 meV) with a very low γ-ray contamination. A description of this facility is given elsewhere[6]. As it is those neutrons which are scattered off the object into the zone plate which form the hologram, as illustrated in Fig. 1*a*, it is necessary to work in as large a neutron flux as possible. Consequently all the experiments were carried out inside the reactor shell wall at a distance of 2 m from the reactor face where foil activation measurements gave a value for the neutron flux strength of 3.3×10^{11} neutrons $\mathrm{m}^{-2}\mathrm{s}^{-1}$.

The Fresnel zone plate was made by photographically etching a zone plate pattern ($r_n = r_1\sqrt{n}$, $n = 1, 2, 3, \ldots$) onto a 1.2-mm thick aluminium alloy sheet to a depth of 100 μm and filling the etched zones with a paint containing gadolinium. The aluminium has a low scattering cross-section and is more than 99% transparent to cold neutrons, whilst the gadolinium is essentially opaque. The plate had 47 zones with a first-zone radius (r_1) of 1.12×10^{-2} m. The holograms were recorded on 0.18 m × 0.24 m X-ray films with a gadolinium foil intensifying screen in front of the film to ensure a linear response in the film emulsion during the relatively long exposure times at these low neutron flux levels. With the recording film 0.4 m from the zone plate which was placed typically at 0.15 m from the objects, with its

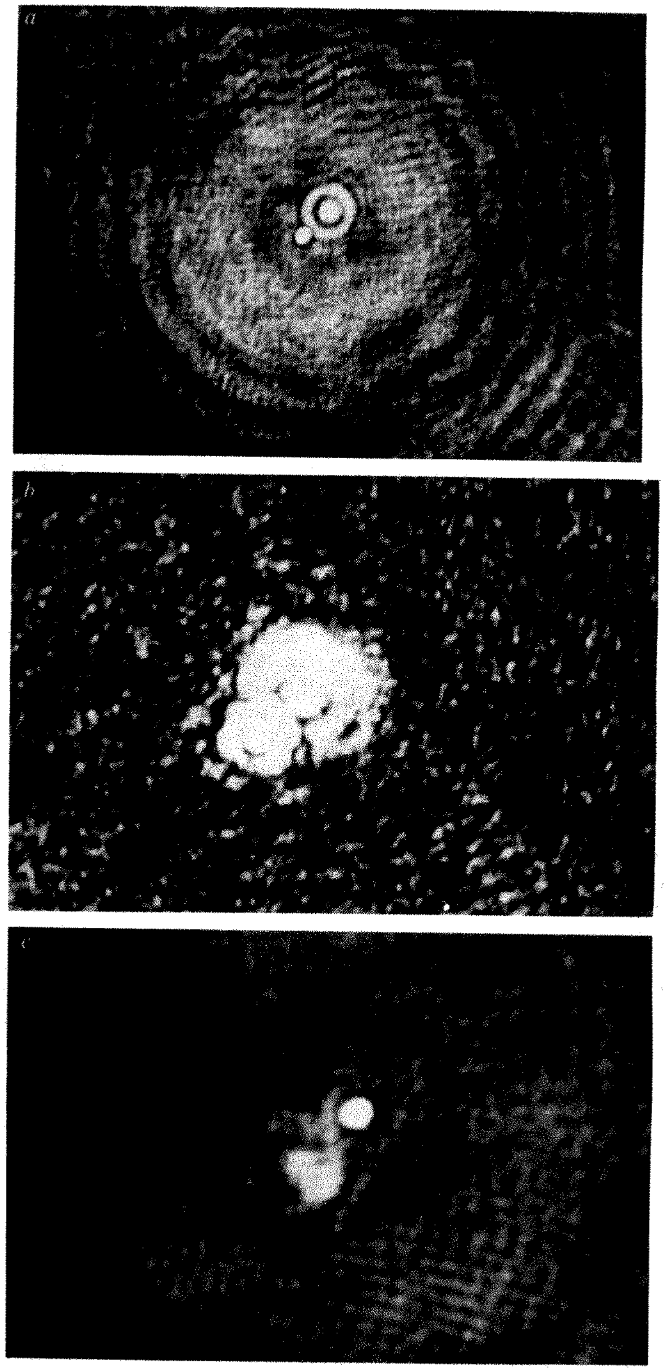

Fig. 2 *a*, A plane through one reconstructed image of sphere (lower left), the other appearing out of focus. *b*, A plane between the spherical images, intersecting neither. *c*, A plane through the second reconstructed image of sphere (upper right), the first image now appearing out of focus.

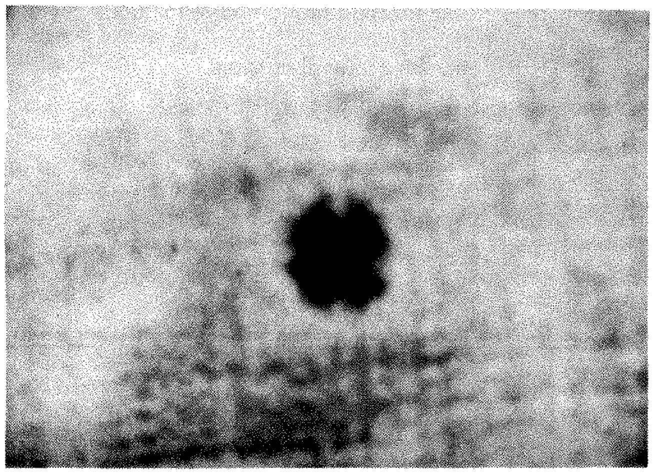

Fig. 3 Optical reconstruction of the Maltese cross.

plane parallel to the beam direction, exposure times using Kodak Industrex C film were 1.5–2 h.

The optical reconstruction was achieved with the arrangement shown in Fig. 1*b*, with a 2 mW helium–neon laser and a transform lens of focal length 0.15 m. Each neutron hologram was linearly reduced in size by a factor of 40 and a conventional transparency made using Agfa-Gevaert high resolution holographic film type 10E56. Note that a bleaching process recommended for this film, which forms the image by having a desensitised silver halide residue rather than silver grains, can produce reconstructed images with considerably enhanced intensity.

We illustrate the effectiveness of the technique using results for two encoded objects of markedly different geometry. The first test object consisted of two rubber spheres, diameter 0.01 m, suspended in the neutron beam with a horizontal and vertical separation of 0.04 m. The second object was a Maltese cross cut from a 0.04 m square of PTFE of thickness 4 mm. The cross was placed with its plane at an angle of 10° to the plane of the zone plate. A series of planes through the reconstructed images have been recorded on standard fine grain photographic film. Figure 2 shows three such planes through the spatially-separated spherical images of the two original spheres. Figure 2*a* is a plane through the first sphere at a distance of one-half radius from the surface; the second sphere appears out of focus. Figure 2*b* is a plane midway between the spherical images and intersecting neither; both images appear out of focus. Figure 2*c* is a plane through the centre of the second spherical image, the first now appearing out of focus. Finally in Fig. 3 we show a plane through the reconstructed image of our PTFE Maltese cross. Figures 2 and 3 are based on image sizes of about 1 mm. Practical applications of this technique would require larger image sizes which could be achieved by using a telescope in the optical reconstruction system of Fig. 1*b*. A more detailed technical discussion of this work, including a description of computer-aided reconstructions of the geometry of the images and an assessment of the limits of resolution of the technique, will be published elsewhere.

We thank V. S. Crocker, G. Constantine and M. R. Anderson of the Materials Physics Division AERE, Harwell for assistance. A.R.P. acknowledges an advanced course studentship from the SRC.

Why noble metals favour the face-centred cubic structure

C. S. G. Cousins

Physics Department, Exeter University, Exeter EX4 4QL, UK

The noble metals (copper, silver and gold) crystallise in the face-centred cubic (f.c.c.) structure but attempts to calculate their cohesive energy[1] and stacking fault energies[2] predict that the stable structure is the hexagonal close packed (h.c.p.). By considering a collinear three-ion interaction I have identified a source of energy, of the correct sign and order of magnitude, that explains the stability of the observed structure. Its success is largely due to a distinctive difference in number and spatial disposition of close-packed lines of atoms in the two structures. The principal parameters of the calculation are the scattering phase shifts of the ions and it is therefore highly probable that three-ion interactions also play a significant part in the stability of the transition metals.

The contributions usually considered in studies of metallic cohesion and stability are the Ewald energy, the core overlap energy, the kinetic, exchange and correlation energies of free electrons, and a band-structure energy that is calculated to second order in perturbation theory. Applying such an approach to the noble metals shows that of the two close-packed structures, the hexagonal one is to be preferred because $\Delta E \equiv E_{\mathrm{fcc}} - E_{\mathrm{hcp}} \approx 0.01$ to 0.003 eV per atom (ref. 1). A related study of stacking fault energies[2], whose principal considerations are the structure-dependent terms in the energy, is also unsuccessful: it predicts positive energies for the h.c.p. structure and negative ones for the f.c.c. Although minor adjustments or refinements to the usual theory might reverse the sign of the calculated ΔE, I believe that the f.c.c. stability is caused by three-ion interactions and that only these can provide the substantial $\Delta E \approx -0.01$ to -0.03 eV per atom needed to explain the measured stacking fault energies.

This idea is supported by Krause[3]; he examined a subtle effect in the lattice dynamics of copper and showed that an interplanar stiffness constant derived from $\langle 111 \rangle T$ phonon dispersion data was incompatible with an exclusively two-body potential.

In a study of multi-ion interactions[4] in simple metals Harrison has drawn attention to a three-ion term in which the ions are collinear and separated by nearest neighbour distances. This is a dominant term because it involves the matrix element for forward scattering and therefore mimics a second order term in

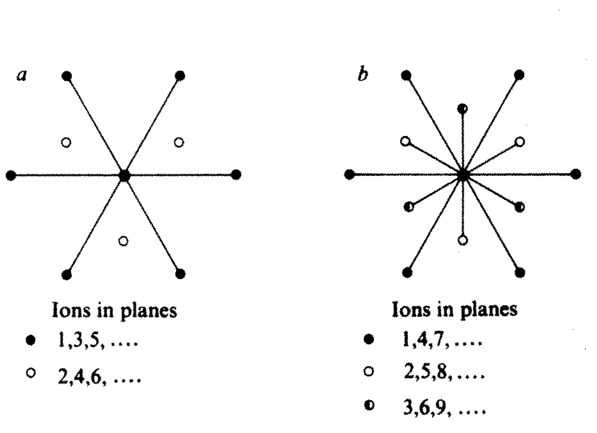

Fig. 1 The disposition of linear triads of ions in the h.c.p. and f.c.c. structures. The projections of ion positions are shown looking down; *a*, the [00.1] axis in the h.c.p. structure; and *b*, the [111] axis in the f.c.c. structure.

0028–0836/80/080751—02$01.00

Table 1 The contribution of the dominant three-ion term to the energy difference between f.c.c. and h.c.p. forms of the noble metals

	Copper			Silver	Gold
E_F* (eV)	6.80	7.48	8.16	5.58	5.58
$\delta(\pi)$	0.009	−0.027	−0.076	−0.072	−0.265
$\delta(0)$	0.748	2.418	2.969	1.260	1.109
ψ	0.766	2.364	2.817	1.116	0.580
$\lvert t(2k_F)\rvert$ (eV)	2.30	2.84	3.41	1.55	1.97
V_0 (eV)	22.1	30.5	40.3	12.2	19.7
Φ_3 (eV per triad)	−0.007	−0.018	−0.015	−0.006	−0.010
ΔE_3 (eV per atom)	−0.022	−0.053	−0.044	−0.019	−0.030

* The free electron values of E_F are 7.00, 5.48 and 5.51 eV respectively.

magnitude. To avoid a complex analysis only this term will be discussed below.

Each atom in an h.c.p. structure is the central atom of three triads which are confined to the close-packed plane (Fig. 1). Each atom in an f.c.c. structure is the central atom of six triads, three lying in the close-packed plane and three spanning three such planes. The net result is a contribution to the energy of the f.c.c. structure that differs from that of the h.c.p. structure by $\Delta E_3 = 3\Phi_3$ where the energy of a single triad is given by

$$\Phi_3 = V_0 8\pi Z \cos(4k_F d + \psi)/(4k_F d)^4 \tag{1}$$

This expression, derived from Lloyd and Oglesby[5], departs from Harrison's pseudopotential treatment in favour of a form based on scattering phase shifts and, therefore, more appropriate to the noble metals. d is the nearest neighbour distance and $(4k_F d)^3 = 192\sqrt{2}\pi^2 Z$, where Z is the valence (unity in the calculation that follows) and $V_0 = 9\pi Z^2|t(2k_F|^2/E_F$ where $t(2k_F)$ is the t-matrix for on-Fermi-surface back scattering and E_F is the Fermi energy. The phase ψ and $|t(2k_F)|$ are derived from the η_l, the scattering phase shifts for an ion evaluated at the Fermi energy, and are given by

$$\psi = 2\delta(\pi) + \delta(0)$$

and

$$|t(2k_F)| = 4E_F|(\alpha(\pi))^2 + (\beta(\pi))^2|^{1/2}/3\pi Z$$

where $\cot \delta(\theta) = \alpha(\theta)/\beta(\theta)$,

$$\alpha(\theta) = \Sigma_l (2l+1) \sin \eta_l \cos \eta_l P_l(\cos\theta)$$

and

$$\beta(\theta) = \Sigma_l (2l+1) \sin^2 \eta_l P_l(\cos\theta)$$

In the limit of small perturbation $|t(2k_F)| \to v(2k_F)$ and $\delta(\pi) \to 0$. Because the perturbation is not small, $|t(2k_F)|/E_F > 0.28$ in the present case, the phase shift method is being used. The data required for the evaluation of equation (1) can be found elsewhere[6,7] in work in which a precise parameterisation of the Fermi surface is given in terms of four phase shifts. Here the Fermi energy is a free parameter and three sets of results for copper have been given[6]. Table 1 contains the parameters derived from these works and the resulting ΔE_3, which ranges from −0.02 to −0.05 eV per atom, and may be compared with the experimental estimates[8] of the intrinsic stacking fault energy: 0.019, 0.010 and 0.022 eV per atom in the fault plane for Cu, Ag and Au respectively. As the contribution of three-ion interactions to the intrinsic stacking fault energy is $-2\Delta E_3$ (ref. 9) it is clear that while these results are in the correct sequence they are, nevertheless, too large. Some reduction in the value of ΔE_3 is to be expected in a full three-ion calculation but a change of sign is highly unlikely. This is because the numbers of the smallest triangular configurations are very similar in f.c.c. and h.c.p. structures. Both have 24 equilateral configurations and 12 configurations with sides in the ratio $1:1:\sqrt{2}$, and neither of these sets can provide an energy difference between the structures. I conclude therefore, that three-ion interactions are exclusively responsible for the stabilisation of the noble metals in the f.c.c. structure.

I thank Dr R. Jones for useful discussions.

^{15}N natural abundance in oceanic suspended particulate matter

Toshiro Saino & Akihiko Hattori

Ocean Research Institute, University of Tokyo, Nakano-ku,
Tokyo 164, Japan

Particulate organic matter (POM) has a central role in the vertical transport of material in the sea[1]. In the open ocean, POM is produced in the euphotic layer by phytoplankton and degraded in the aphotic layer during sinking to the sea floor. Isotopic abundance of biophilic elements such as C and N in POM is altered by isotopic fractionations associated with biochemical reactions[2]. Natural abundances of ^{13}C or ^{15}N thus provide useful information on biochemical behaviour of POM in the sea. We report here the first comprehensive data on the vertical distribution of ^{15}N in suspended POM[3] collected at a station in the northeastern Indian Ocean. Also, we discuss how nitrogen isotopic analysis could be used for the identification and quantification of the vertical transport processes.

Williams and Gordon[4] have investigated ^{13}C abundances in suspended particulate organic carbon (POC) collected from the eastern North Pacific, between 10 and 2,940 m, the δ^{13}C values fell in the narrow range −22.0 to −24.3 ‰. They suggested that most of the suspended POC is biologically refractory. A variation of δ^{13}C in POC with depth was later demonstrated by Eadie and Jeffrey[5]; POC in deeper layers (>330 m) was significantly lower in ^{13}C than that in shallower layers. C/N ratios of suspended POM increase with depth[6]. This implies that nitrogen is more rapidly lost than carbon during degradation of suspended POM. Therefore, a much greater variation of ^{15}N abundance in suspended particulate organic nitrogen (PON) is expected than in ^{13}C in POC.

Seawater samples were collected with Van Dorn bottles (25 l) from various depths or with a plastic bucket from the sea surface on Cruise KH-76-5 of Hakuho Maru, University of Tokyo[7]. 20–23 l of seawater was filtered through a precombusted (400 °C, for 1 h) Reeve Angel 984H glass fibre filter (47 mm diameter). The POM collected on the filters was desiccated over silica gel *in vacuo*. The procedures for conversion of PON to nitrogen gas and its purification have been described elsewhere[8]. The total nitrogen and its ^{15}N content were determined simultaneously using a Hitachi RMU-6E mass spectrometer fitted with a double collector and a dual inlet system. Sufficient nitrogen gas was introduced into the mass spectrometer to produce an output signal at $m/e = 28$ of greater than 7 V. Isotopic ratio measurements were repeated at least four times for each sample and averaged. Two sources of reagent grade ammonium sulphate (δ^{15}N; −6.7 and −1.5‰ relative to atmosheric nitrogen) were used as isotopic standards. Reproducibility of each measurement was ±0.3‰.

Table 1 summarises the δ^{15}N values of duplicate samples collected from the sea surface at 12 different locations. Differences in the δ^{15}N of the duplicate determinations ranged

0028-0836/80/080752—03$01.00

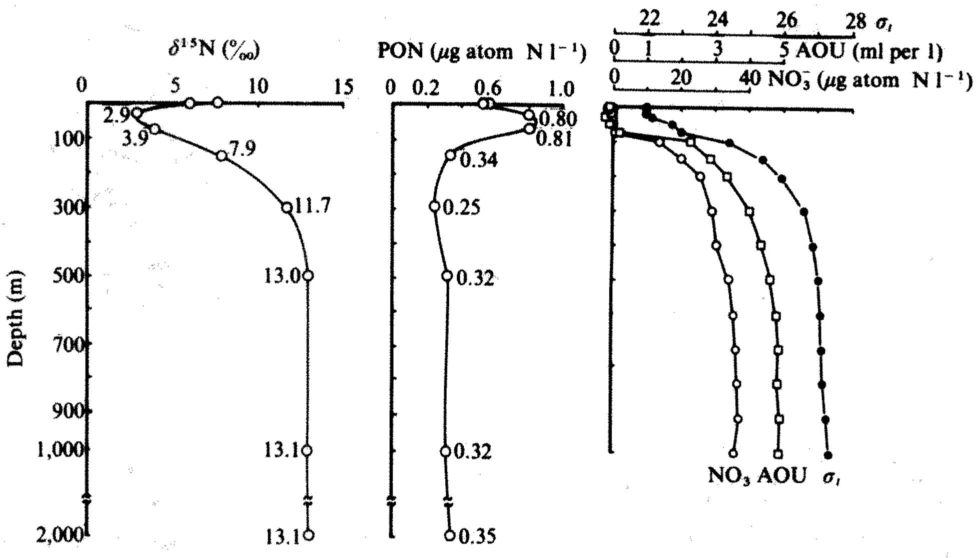

Fig. 1 Vertical distribution of $\delta^{15}N$, PON, σ_t, AOU and NO_3^- at Station 5 in the northeastern Indian Ocean on 11 January, 1977. Water samples for temperature, salinity, dissolved oxygen and nitrate determinations were collected with Nansen bottles equipped with reversing thermometers. Nitrate was measured using a Technicon Autoanalyser II on board the ship. σ_t and AOU are cited from the cruise report[7].

from 0.3 to 2.5‰, averaged 1.4‰. Heterogeneity in the distribution of POM and in its isotopic composition may partly cause this variation[8].

Figure 1 presents the vertical distribution of $\delta^{15}N$ along with PON, σ_t, apparent oxygen utilisation (AOU)[9] and nitrate at a station located in the northeastern Indian Ocean. $\delta^{15}N$ decreased near the surface reaching a 2.9‰ minimum at 30 m and then increased through the 30–500 m depth by ~10‰. Below 500 m the $\delta^{15}N$ remained constant (~13‰). Conversely, PON increased near the surface and attained a maximum between 30 and 75 m. The abundance of ^{15}N in marine organisms has been shown to increase with increasing trophic level[10]. The $\delta^{15}N$ values for PON collected from the euphotic layer (<150 m), where production of POM exceeds its degradation, are similar to those for phytoplankton while the $\delta^{15}N$ values for PON from depths >300 m are similar to those of zooplankton or fish.

The increase of $\delta^{15}N$ with depth parallels the increase in σ_t, AOU and nitrate. This suggests that the ^{15}N enrichment in PON with depth results from isotopic fractionation during oxidative degradation of PON. Wada[11] has found that $\delta^{15}N$ increases by 3–4‰ during the early period of oxidative degradation of dead phytoplankton and zooplankton at room temperature and atmospheric pressure. Our results suggest that degradation of PON actively proceeds in the upper 500 m, leaving refractory components which sink into the deep layers.

Low values for $\delta^{15}N$ in the subsurace PON may result from isotopic fractionation associated with nitrate uptake by phytoplankton in light-limited conditions, because growth of phytoplankton in this subsurface layer is mainly supported by nitrate[12]. Preferential utilisation of ^{14}N-nitrate over ^{15}N-nitrate by marine diatoms has been reported[13]. The ^{15}N enrichment of nitrate in eastern Pacific shallow waters over that in deeper waters also supports this view[14].

In the surface layer of the tropical Indian Ocean, the concentrations of nitrate are extremely low, and the growth of phytoplankton is mainly sustained by regenerated ammonia[15]. Under these circumstances, isotopic fractionation is minimal and the relatively high $\delta^{15}N$ values for surface PON can be attributed to a rapid recycling of nitrogen[16].

There are two main mechanisms for the vertical transport of particulate matter in the sea: (1) transportation mediated by slowly sinking fine suspended particles, which are easily collected on filters by filtering small amounts of seawater; and (2) transportation mediated by rapidly sinking larger particles such as faecal material, which are not collected adequately by conventional water sampling[3], but can be collected by *in situ* filtration of large seawater volumes[17] or by use of sediment traps[18,19].

The $\delta^{15}N$ values reported for organic nitrogen in marine sediments are 10‰ or less[10,20]. The $\delta^{15}N$ values for suspended PON in deep water is much higher (Fig. 1). If the organic nitrogen in sediments is solely supplied by suspended PON, the lower sediment organic nitrogen $\delta^{15}N$ values are difficult to explain. A recent survey that we conducted in the northern North Pacific found that PON collected with sediment traps is invariably less enriched with ^{15}N ($\delta^{15}N$, 2.9–4.4‰) than are sediments, irrespective of the collection depth (1.1–5.25 km). Simultaneous determinations of ^{15}N abundance in suspended PON, settling PON collected with sediment traps, and sedimentary organic nitrogen should provide an estimate of the relative contribution of suspended and settling PON to the organic nitrogen in bottom sediments, and may provide a way of assessing the importance of these processes in the vertical transport of particulate material.

Table 1 $\delta^{15}N$ and PON at the sea surface

^{15}N abundance is presented in terms of $\delta^{15}N$ as defined by the equation:

$$\delta^{15}N = \frac{(^{15}N/^{14}N)\ \text{sample} - (^{15}N/^{14}N)\ \text{standard}}{(^{15}N/^{14}N)\ \text{standard}} \times 10^3$$

This work was supported partially by grant 211111 from the Ministry of Education, Science and Culture, Japan. We thank Drs John J. Goering and E. Wada, for helpful criticisms, also the officers and crew members of the RV Hakuho Maru and the scientists aboard the KH-76-5 Cruise for their cooperation and assistance.

Pyroclastic sulphur eruption at Poás volcano, Costa Rica

P. W. Francis, R. S. Thorpe & G. C. Brown

Department of Earth Sciences, The Open University,

The recent Voyager missions to Jupiter have highlighted the role of sulphur in volcanic processes on Io[1-7]. Although fumarolic sulphur and SO_2 gas are almost universal in terrestrial active volcanoes, and rare instances of sulphur lava flows have been reported[8,9], sulphur in a pyroclastic form has only been described from Poás volcano, Costa Rica[10]. Here we amplify the original descriptions by Bennett and Raccichini[10] and describe a recent eruption of pyroclastic sulphur scoria and ejected blocks that are characterised by miniature sulphur stalactites and stalagmites.

Poás volcano is a small composite volcano (height 2,700 m, basal diameter 20 km) with a deep central crater 1.5 km wide and 300 m deep, in the floor of which is a smaller crater 400 m in diameter containing a hot (~50 °C) crater lake. Intermittent eruptions take place from one or more sites within the crater lake. These are generally small geyser-like plumes of steam and mud, but are occasionally much more vigorous, ejecting large, altered blocks, and more rarely, fragments of juvenile material. Small eruptions were taking place at intervals of roughly 20 min through much of 1978, but seem to have ceased since September 1978.

Bennett and Raccichini[10] noted the presence of greenish sulphur particles up to 4.5 cm in diameter around the crater in 1977. The particles resemble basaltic scoria in size and shape, and their nature and distribution indicated that they have been erupted as a shower of molten particles. Bennett and Raccichini attributed the 'sulphur scoria' to a 'lake' of molten sulphur located beneath the water in the floor of the crater, and estimated that 'several hundred tonnes' of sulphur were lying on the surface around the crater.

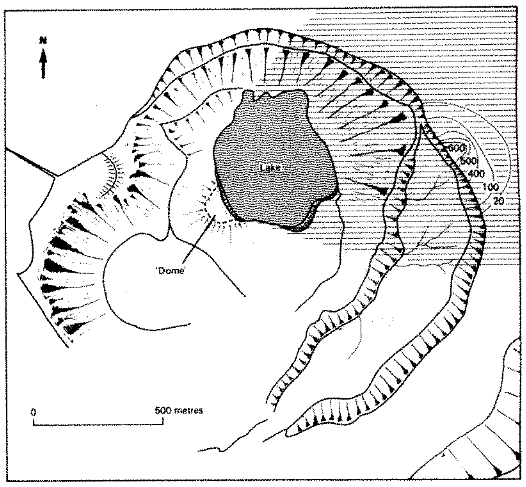

Fig. 1 Map of summit area of Poás volcano. Horizontal lines, area covered by ejected blocks. Numbered contours, surface concentration of sulphur particles in g m^{-2}.

We have carried out observations at Poás during January 1978 and February–March 1979. On the former occasion, frequent small eruptions and one large eruption took place; on the latter occasion, no eruptions were observed. In 1978 we were able to confirm Bennett and Raccichini's descriptions of scoriaceous sulphur particles dispersed widely, but sparsely, around and within the crater. At that time some of the sulphur was observed lying at, or near, the surface of an andesitic ash erupted in 1953 (ref. 11), and it therefore post-dates that eruption. Much the greatest proportion of the scoriaceous sulphur, however, had been washed downslope and had accumulated locally as deposits many centimetres thick. These deposits were striking on account of their greenish colour, and the shapes of the particles within them, some of which resembled Pele's tears which are characteristic of fluid basaltic eruptions[12].

In September 1978 a large eruption took place. Although poorly observed and recorded, due to persistent cloud covering the volcano, rangers of the Costa Rica National Park Service reported hearing loud explosions and seeing small, but widespread, blue flames around the crater rim after the eruption, and that the level of water in the lake had decreased sufficiently for

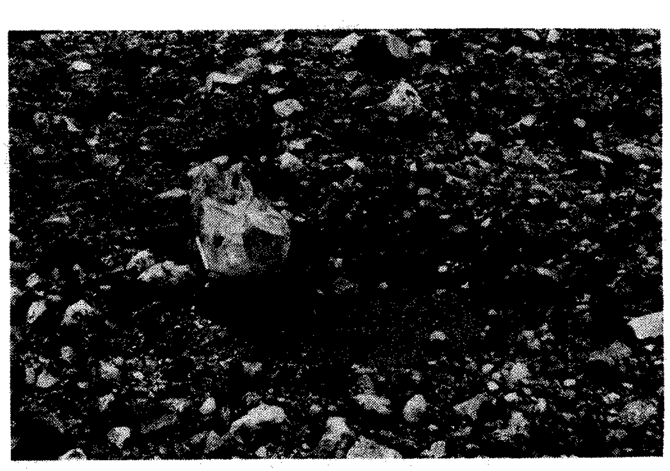

Fig. 2 Typical small ejected block and impact crater or eruption of September 1978. Note asymmetric position of block on crater rim; direction of travel was from right to left.

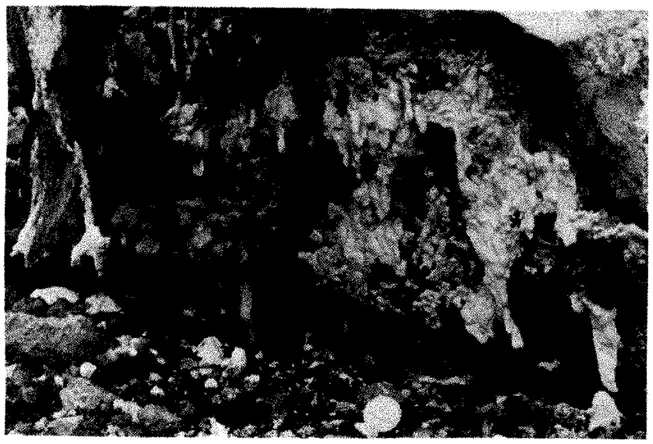

Fig. 3 Sulphur encrusted face of an ejected block, showing stalactites of sulphur. Stalactite and stalagmite nearly connect at right. The coin is 2.1 cm in diameter.

the bottom to be exposed in places. Our visit in February 1979 confirmed that at least one powerful explosive event had taken place, as the eastern flanks of the volcano were littered with fresh impact craters and large ejected blocks (Fig. 1). New fragments of green scoriaceous sulphur were abundant on the eastern rim of the crater, locally sufficient to cover the surface entirely. The distribution of the sulphur was studied by weighting the amounts found within individual 1-m square grids, and constructing a contoured map (Fig. 1). The greatest concentration of sulphur is on the east rim of the crater, whereas most of the older ashes have accumulated on the north and northwestern flanks, in response to the prevailing winds. This indicates that the sulphur particles were deposited by a directed blast, rather than falling from a wind-blown eruption cloud. A total of ~ 4 tonnes of pyroclastic sulphur particles lies on the surface examined, which suggests a total for the eruption of some 10–15 tonnes, allowing for sulphur which fell within the crater itself. Grain size analysis of the sulphur shows that, in size distribution and sorting characteristics, it resembles the basaltic ash of 1953 (unpublished data).

The asymmetrical distribution of the impact craters and ejected blocks from the September 1978 eruption also indicates a directed blast (Fig. 1). Blocks 0.3 m in diameter were found occupying craters 1.5 m in diameter several hundred metres from the crater rim. In most cases, the trajectories followed by the blocks were nearly tangential to the gently sloping flanks of the volcano and many blocks were therefore found lying at one side of their craters, or had bounded out of their initial craters and travelled onwards (Fig. 2). Measurement of the final resting places of the blocks relative to their impact craters enabled the azimuths of their trajectories to be estimated and the approximate site of initial ejection to be located. This corresponds closely with a breached dome on the crater floor, which is also the site of continuous intense fumarolic activity, and is heavily encrusted with fumarolic sulphur deposits.

Examination of the blocks revealed three distinct types to be present: (1) poorly consolidated lumps of grey clay and mud which had clearly been derived from the floor of the crater lake; (2) blocks of fresh, dark basaltic material which may represent the juvenile component involved in the eruption; and (3) heavily altered, sulphur encrusted blocks probably derived from the site of the active fumaroles. The sulphur encrusted blocks are concentrated towards the centre of the bombed zone, which corresponds closely to the area of maximum pyroclastic sulphur deposition. The distribution of the pyroclastic material is consistent with a powerful explosion having taken place at the foot of the cliffs at the present fumarole site, so that most of the ejecta were blasted out towards the east. A similar explosion may have taken place in 1964, as Krushensky and Escalante[13] described sulphur encrusted blocks in the ejecta from that eruption.

The unique aspect of the blocks ejected in 1978 is illustrated in Fig. 3. After coming to rest, the molent sulphur on the exterior surfaces of the ejected blocks dribbled downwards, dripping off projecting points to form stalactites, and accumulating on the surface beneath as stalagmites a few centimetres high. The formation of these features after the blocks came to rest is indicated by their vertical orientations, and by the formation of stalagmites on the loose ash and gravel of the preexisting surface. In a few cases, blocks were found exhibiting stalactitic features which were not vertical. These may have been produced during heating of the blocks before the eruption.

In contrast to the green scoriaceous sulphur resting on the surrounding surfaces, the sulphur encrusting the ejected blocks is strikingly yellow in colour. The difference in colour may represent an original difference in temperature of formation, or rate of cooling. An impression of the physical state of the yellow sulphur during stalactite formation is afforded by the fact that each stalagmite is formed of 20–30 individual pancake-like blobs of sulphur piled on top of each other and fused together. Clearly, the sulphur drips were at or near the melting point of sulphur, but the liquid sulphur was also of low viscosity.

As Sagan emphasised[5], the viscosity of liquid sulphur at its melting point is ~ 0.1 P but increases by a factor of 10^3 to a value exceeding 10^2 P between 157 and 187 °C. Thus while the sulphur on the ejected blocks cannot have greatly exceeded the melting point (110–119 °C), the green scoriaceous sulphur may have achieved temperatures of up to 200 °C, because the morphology and grain size characteristics of the fragments (unpublished data) are strikingly similar to those of true basaltic scoria formed from liquids with viscosities between 10^3 and 10^4 P (for example, data summarised in ref. 14).

Although it is curious that they have not been described before, the small stalagmites and stalactites on the ejected blocks seem to have a relatively straightforward origin. During the week before the large eruption of January 1978, we observed a marked increase (~ 10 °C) in the temperature of the fumaroles in the dome on the crater floor. The highest temperatures recorded were well above the melting point of sulphur. Presumably, a similar temperature rise preceded the eruption of September 1978, and was sufficient to melt the sulphur contained in a large volume of rocks surrounding the fumaroles. The molten sulphur accumulated in joints and fractures in the rock until the explosive eruption took place, and broke up the original mass into a large number of smaller blocks, and hurled them across the crater. Liquid sulphur still adhering to the joint faces of the blocks was partially stripped off in flight, but sufficient still remained on impact to dribble to the ground, forming stalactites and stalagmites.

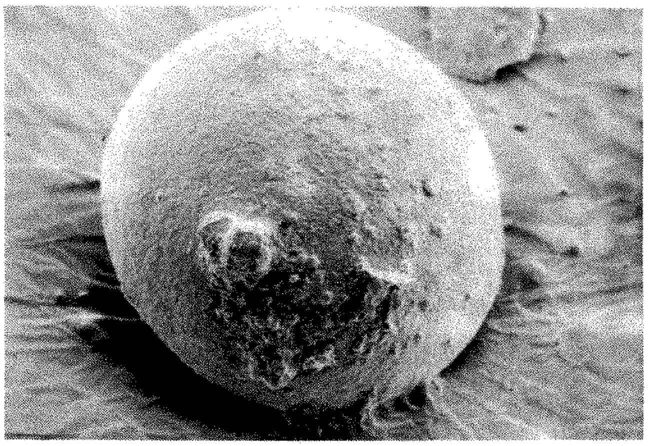

Fig. 4 Scanning electron micrograph of sulphur sphere from Poás lake mud. Sphere is 500 μm in diameter.

The scoriaceous sulphur is more difficult to account for. The 10–15 tonnes erupted in 1978 must have had a similar origin to that described by Bennett and Raccichini. They, however, reported the ejection of 'several hundred tonnes' of sulphur[10], which may be the products of several similar eruptions over a period of time.

We consider it unlikely that a 'lake' of liquid sulphur existed within the crater, as proposed by Bennett and Raccichini, but it seems probable that liquid sulphur congregated in fissures and pore spaces in the volcanic conduit beneath the site of the active fumaroles, and that this was sprayed into the air during the explosive eruption of September 1978.

The presence of water in the crater lake seems to have played an important part in this unusual eruption. Initially, it was responsible for sealing off the liquid sulphur from contact with the air, thus preventing its combustion or oxidation. Subsequently, interaction of the molten sulphur with lake water may have been responsible for the vigour of the eruption, and for the shaping of some of the sulphur particles. Evidence for this is the presence, within the lake muds and floating on the lake surface, of myriads of tiny spheres of sulphur (Fig. 4), which may have been produced when a spray of liquid sulphur was blasted into the lake water from beneath. We do not consider that temperatures as high as the boiling point of sulphur (444 °C) suggested by Bennett and Raccichini are necessary to explain the observed phenomena, particularly as the viscosity of liquid sulphur decreases between 200 and 444 °C (see ref. 5).

Although sulphur has an important tole in terrestrial volcanism, it is clearly dominant in ionian volcanic processes[1–7]. On Earth, sulphur and sulphur gases are an important component of explosive volcanic activity[15] and commonly form up to 30% of volcanic gases[16] which are removed from the atmosphere by surface processes. However, sulphur lavas and pyroclastic rocks as described here from Poás are relatively rare. On Io, sulphur dioxide is the dominant gas in the sustained volcanic plumes and sulphur may be a major component of the ionian crust[4,5]. Assuming that both have approximately chondritic Fe:S:Si ratios, the difference in surface sulphur concentration between Earth and Io presumably lies in their internal structures. Assuming the presence of a massive Fe–FeS core in the Earth[17] the magmatic source regions for terrestrial volcanic rocks must be relatively depleted in sulphur. On Io, by contrast, vigorous internal convection driven by tidal dissipation[18] might have been responsible for less efficient core formation and for less efficient partitioning of sulphur into its putative core.

Volcanic observations on Poás were made during visits in 1978 and 1979 sponsored by Earthwatch (Educational Expeditions International) and the Centre for Field Research (Belmont, Massachusetts). We thank R. Chavez and the Universidad Nacional at Heredia for fieldwork assistance in Costa Rica. We thank R. W. Carlton for SEM photography, and E. M. Shoemaker for helpful comments.

Rb–Sr age and source of the Bimodal Suite of the Ancient Gneiss Complex, Swaziland

J. M. Barton*, D. R. Hunter†, M. P. A. Jackson† & A. C. Wilson‡

*Bernard Price Institute of Geophysical Research, University of The Witwatersrand, 1 Jan Smuts Avenue, Johannesburg 2001, South Africa

‡ Institute of Geological Sciences, Keyworth, Nottingham NG12 5GQ, UK

The Ancient Gneiss Complex (AGC) in Swaziland[1–5] is a complexly deformed suite of gneisses that may be divided into three major units[5]: (1) the Biomodal Suite (BMS) of interlayered siliceous low-K leucocratic orthogneisses and amphibolites; (2) homogeneous tonalitic gneiss (the ~3,320 Myr old Tsawela gneiss)[6,7]; and (3) supracrustal rocks constituting two main lithologic sequences—the Mkhondo Valley[1,5] and Dwalile (ref. 8 and M.P.A.J. and A.C.W. unpublished data) metamorphic suites. The Tsawela gneiss is intrusive into both the BMS and the Dwalile metamorphic suite[8]. Relating the BMS to the greenstone sequence of the Barberton Mountain Land (the Onverwacht Group of the Swaziland Supergroup) has caused much controversy. It has been thought[1] that the BMS predates the Onverwacht Group and may represent a basement to the latter. Another view[9,10] is that all of the leucocratic gneisses of the AGC are younger than the Onverwacht Group and were derived from an unrelated mantle source. The amphibolite and metasedimentary rocks in the AGC are xenoliths of the Swaziland Supergroup. This controversy has remained unsolved due to the lack both of unambiguous contact relationships between the AGC and the Swaziland Supergroup, and of reliable radiometric data on the emplacement age of either unit. At the only known locality where these two units are juxtaposed, the contact is tectonically deformed. Early radiometric age data[6,11–20] have given results that are either too imprecise or reflect subsequent metamorphism[7]. Recently, however, a precise age of 3,510 ± 60 Myr (2σ) has been obtained by the Sm–Nd technique for extrusion of the volcanic rocks of the Komati Formation of the lower Onverwacht Group[21]. The results are reported here of Rb–Sr whole rock and biotite–whole rock isotopic analyses of samples of the leucocratic orthogneisses of the BMS. Results are also presented of initial ^{87}Sr/^{86}Sr ratio studies of samples of amphibolite from the Komati Formation. The relationship of the AGC to the Swaziland Supergroup is re-examined. All Rb–Sr ages mentioned are calculated using 1.42×10^{-11} yr^{-1} as the decay constant of ^{87}Rb.

The BMS has been intruded by the ~3,320 Myr old Tsawela gneiss[6,7], the ~3,030 Myr old Lochiel (Homogeneous Hood) granite (refs 15, 22 and J.M.B., unpublished data) and mafic dykes. Faulting and mylonisation in some areas have intensely deformed the BMS gneisses and fresh exposures of the BMS commonly look like smooth pavements. It is, therefore, difficult to obtain unaltered samples of the BMS in the type locality near Mankayane (Fig. 1). However, a quarry has recently been opened near the Fairview Dam in north-central Swaziland (Fig. 1) where the BMS is largely free from younger pegmatitic veins but is intruded by two generations of basic dykes. Vein-free samples of the leucocratic orthogneisses of the BMS were collected in this quarry at least 50 m from the dykes.

The analytical techniques used are described elsewhere[23,24]: the results are summarised in Table 1. Regressing the results of whole rock analyses of the leucocratic orthogneisses of the BMS[25] yields an isochron $(\mathrm{SUMS}/(n-2)=\mathrm{MSWD}=0.31<$

* Uncertainty = 1.4% (2σ)
† Uncertainty = 0.02% (2σ)
‡ Calculated for 3,510 Myr.
§ Biotite. The biotite–whole rock age was calculated from sample B-79-8B.
[11] Ref. 18. [1A] Ref. 19.

2.5) (ref. 26) of 3,555 ± 111 Myr (2σ) with an initial ^{87}Sr/^{86}Sr ratio of 0.6999 ± 0.0016 (2σ) (Fig. 2) (MSWD, mean square of weighted deviates). A biotite–whole rock age of ~2,889 Myr was also obtained.

The very low initial ^{87}Sr/^{86}Sr ratio of the whole rock isochron suggests that the calculated age corresponds closely to the time of emplacement of these rocks. This age is indistinguishable from the ~3,510 Myr age[21] of emplacement of the volcanic rocks of the Komati Formation, implying that these two units are radiometrically coeval. The leucocratic orthogneisses of the BMS, at least where sampled, cannot be a much older basement to the Onverwacht Group of an age similar, for example, to the > ~3,790 Myr old Sand River Gneisses of the Limpopo Mobile Belt[27]. The biotite–whole rock age implies that the major deformations manifested in the rocks of the BMS occurred by ~2,890 Myr ago. In view of their closeness, the major deformations displayed in the rocks of the Swaziland Supergroup, broad open and recumbent isoclinal folding[28], had also probably taken place by this time.

Unaltered samples of volcanic rocks from the Swaziland Supergroup have not yet been collected and all of the samples analysed so far have been metamorphosed to at least greenschist facies. The lack of deformation fabrics in many of these samples suggests that their mineral composition is not due to regional metamorphism in the conventional sense, but more probably to deuteric alteration. In addition, because no Rb–Sr whole rock isochrons corresponding to an age of ~3,510 Myr have been generated from samples from the Komati Formation, no direct determination of the initial ^{87}Sr/^{86}Sr ratios of these rocks have been made. Part of the scatter in the analytical results may reflect open system behaviour. However, in view of the ~3,430 Myr mineral isochron age derived from a single sample of the Komati Formation[19], the data scatter more probably reflects a range in initial ^{87}Sr/^{86}Sr ratios established within these rocks before this time. Part of this range may be attributed to chemical changes during deuteric alteration but some may also reflect a genuine range in ^{87}Sr/^{86}Sr ratios in the magmas themselves. Deuteric alteration generally increases the ^{87}Sr/^{86}Sr ratio of the rocks. Therefore, the maximum initial ^{87}Sr/^{86}Sr ratio of each sample may be estimated by subracting the radiogenic ^{87}Sr component that would have been generated over 3,510 Myr to leave the present ^{87}Rb/^{86}Sr ratio from the measured ^{87}Sr/^{86}Sr ratio. Results from the extrusive rocks of the Komati Formation have been treated this way in Table 1. Isotopic data[19] from sills and other differentiated intrusive bodies in the Komati Formation have been omitted because of uncertainty in their age with respect to the Komati Formation and their obviously altered composition[19]. The data from the extrusive rocks yield an average maximum initial ^{87}Sr/^{86}Sr ratio of 0.7001 ± 0.0006 (2σ). It seems, therefore, that the Komati Formation is not only coeval with the leucocratic orthogneisses of the BMS, but that the initial ^{87}Sr/^{86}Sr ratios of these units are indistinguishable.

These data are consistent with the possibility that the leucocratic orthogneisses of the BMS and the extrusive rocks of the Komati Formation are genetically related. It has been suggested from REE analyses[5] that these orthogneisses were derived from partial melting of basalt or amphibolite[29], having similar chemical compositions to the extrusive rocks of the Komati Formation. It is possible, therefore, that the rocks of the Komati Formation represent the parent that, on partial melting, yielded the leucocratic component of some of the BMS. The amphibolite in the BMS then could be remnants of the Komati Formation.

However, recent findings in southeastern Swaziland oppose this age relationship. In the western part of the Mankayane type area (Fig. 1), the BMS is in conformable contact with strongly distorted and disrupted metasupracrustal rocks, lithologically akin to the Onverwacht Group, known as the Dwalile metamorphic suite (ref. 8 and M.P.A.J. and A.C.W., unpublished data). These rocks have not been dated but are older than the ~3,320 Myr old[6,7] Tsawela gneiss that intrudes them (ref. 8 and M.P.A.J. and A.C.W., unpublished data). The original relationship between the BMS and the Dwalile suite is obscured by repeated episodes of high strain. Nevertheless, the metasupracrustal rocks are commonly preserved in the cores of synforms and no field relationships nor structures indicating that the BMS is younger than the Dwalile suite have been observed. Furthermore, the lower amphibolite grade of the rocks at Dwalile suggests a higher crustal level of metamorphism than that of the rocks of the BMS that are metamorphosed at upper-amphibolite facies (ref. 2 and M.P.A.J. and A.C.W., unpublished data). Available structural and metamorphic

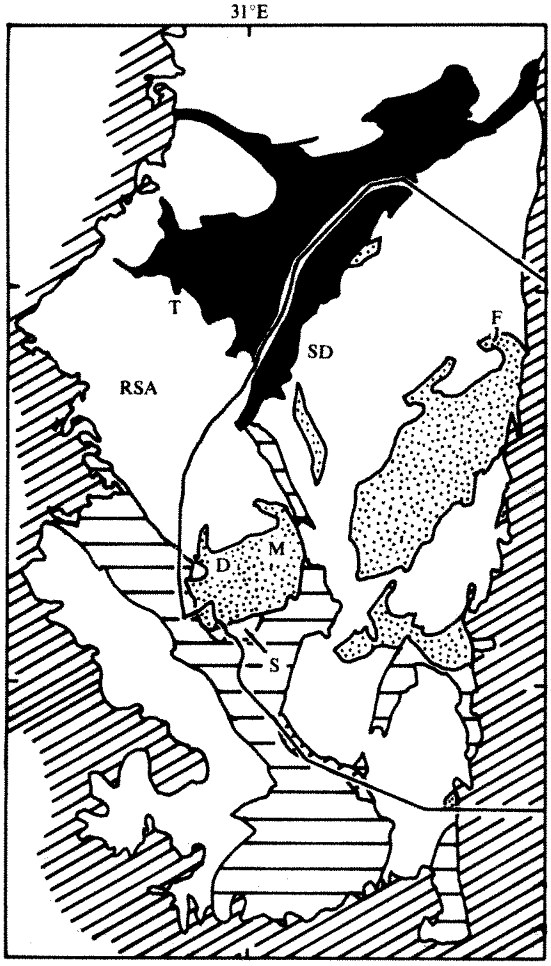

Fig. 1 A simplified geological map of the Barberton Mountain Land and the area to the south modified from Hunter[2]. ■, Swaziland Supergroup. ▒, Ancient Gneiss Complex. □, Younger granitoid intrusions. ▤, Pongola Group and the Ushushwana Complex. ▨, Transvaal and Karroo Supergroups. evidence therefore suggests that a basement–cover relationship exists between the BMS and the Dwalile suite. If this is true, it follows that the parent rocks of the BMS here could be older than the Komati Formation. The rocks classified in the BMS at the type locality may be different from those at the Fairview Quarry.

The initial $^{87}Sr/^{86}Sr$ ratio of the leucocratic orthogneisses of the BMS and those postulated for the Komati Formation are small and plot on the commonly proposed oceanic mantle Sr-isotopic growth curves[30,31]. These curves reflect oceanic mantle depleted in Rb with respect to Sr. Both the leucocratic orthogneisses and the Komati Formation may be derivatives of this type of mantle.

Mesozoic complementary crust in the North Atlantic

K. Rohr

Woods Hole Oceanographic Institution and Massachusetts Institute of Technology, Woods Hole, Massachusetts 02543

W. Twigt

Vening Meines Laboratory, University of Utrecht, The Netherlands

Detailed surveys of complementary oceanic crustal sections have been carried out over Mesozoic magnetic anomalies M4–M0 (~116–110 Myr BP) in the North Atlantic Ocean. We report here reconstructions of these crustal sections, one on the North American plate and one on the African plate, as they once existed together at the ridge crest using a statistical least squares technique, as well as by eye. The reconstructions allow a test of plate rigidity and consequently a refinement of the reconstruction of the whole North Atlantic in these times. Previous reconstructions had the uncertainty that the correct sections were being matched; the gentle curvature of the Mesozoic plate boundary provides little constraint along the strike of the boundary. The unique local pattern of the magnetic anomalies and their offsets in the surveyed areas allows an unambiguous match.

0028–0836/80/080758—04$01.00

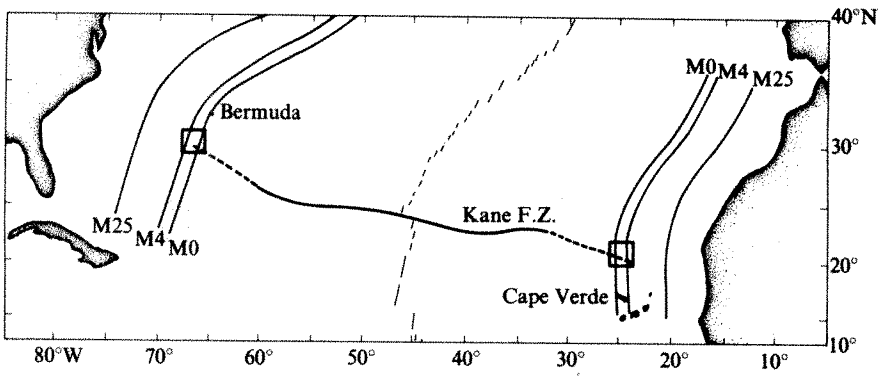

Fig. 1 Locations of two detailed survey sites.

On the North American plate a detailed geophysical survey of an approximate 1° square south of Bermuda was conducted in 1975 as part of the International Phase of Ocean Drilling[1] (Fig. 1). The additional magnetic data are from RV Atlantis II, RV Chain, USNS Keathley and a Project Magnet aeromagnetic survey[2]; fracture zone positions were picked from a Project Magnet magnetic anomaly contour map[3] on the basis of steep gradients, truncation of linear anomalies, and the presence of localised anomalies (Fig. 2*a*). The complementary crust on the African plate was surveyed by the Vening Meinesz Laboratory on board the MV Tyro in a 1° by 2° area north of the Cape Verde Islands in 1978 (Fig. 1). Additional magnetic and seismic data were obtained from the HMNS Snellius, RV Atlantic II, RV Vema, RV Conrad, USNS Gibbs, USNS Discoverer, and the USNS Kane. Fracture zone positions on the African plate were determined from seismic reflection data and picked as the deepest part of the trough (Fig. 2*b*).

The uniqueness of the magnetic pattern confirms that the two data sets are complementary. The survey on the North American plate showed that two left lateral fracture zones exist roughly 75 km apart and that the offsets across the fracture zones changed between M4 and M0 time. On the southern fracture zone the offset increased from ~15 to 35 km, and on the northern fracture zone decreased from ~40 to 30 km. These changes in fracture zone offset were accommodated by asymmetric spreading and rotation of the accretion axis[1]. An examination of the western Atlantic magnetic lineation map as compiled by Schouten and Klitgord[4] shows that this pattern of M4 and M0 lineations is unique. Finding the same pattern on the African plate, then, proves that the surveys are of complementary pieces of crust. On the African plate two left lateral fracture zones 75 km apart were surveyed; offsets for M4 and M0 were 15 and 35 km on the southern fracture zone and 40 and 30 km on the northern fracture zone (Fig. 2*b*).

On the African plate the location of the survey was predicted by rotating the North American data to Africa (Fig. 3*a*) by the M0 pole of Schouten and Klitgord (personal communication). This 'initial' Schouten and Klitgord pole is based solely on shipboard magnetic anomaly positions, the data set consists of ~60 anomaly identifications for each plate, spread over 23° in the central North Atlantic. In this reconstruction, the trends of the anomalies match quite well, but the predicted fracture zone positions fall roughly 20 miles south of the surveyed positions.

Poles of rotation which bring the estimated transform faults into better alignment were calculated for the two detailed data sets. Considering the density of data it seemed reasonable to use the least squares method of Hellinger[5] which gives a statistical best fit. Poles were also calculated from a visual fit to allow a comparison of methods.

The least squares method takes into account the estimated error for each data point; a computer program searches for the best fitting pole and angle of rotation within a specified area and range. The data are split into segments of spreading ridges and transform faults; data in a given segment from each plate are

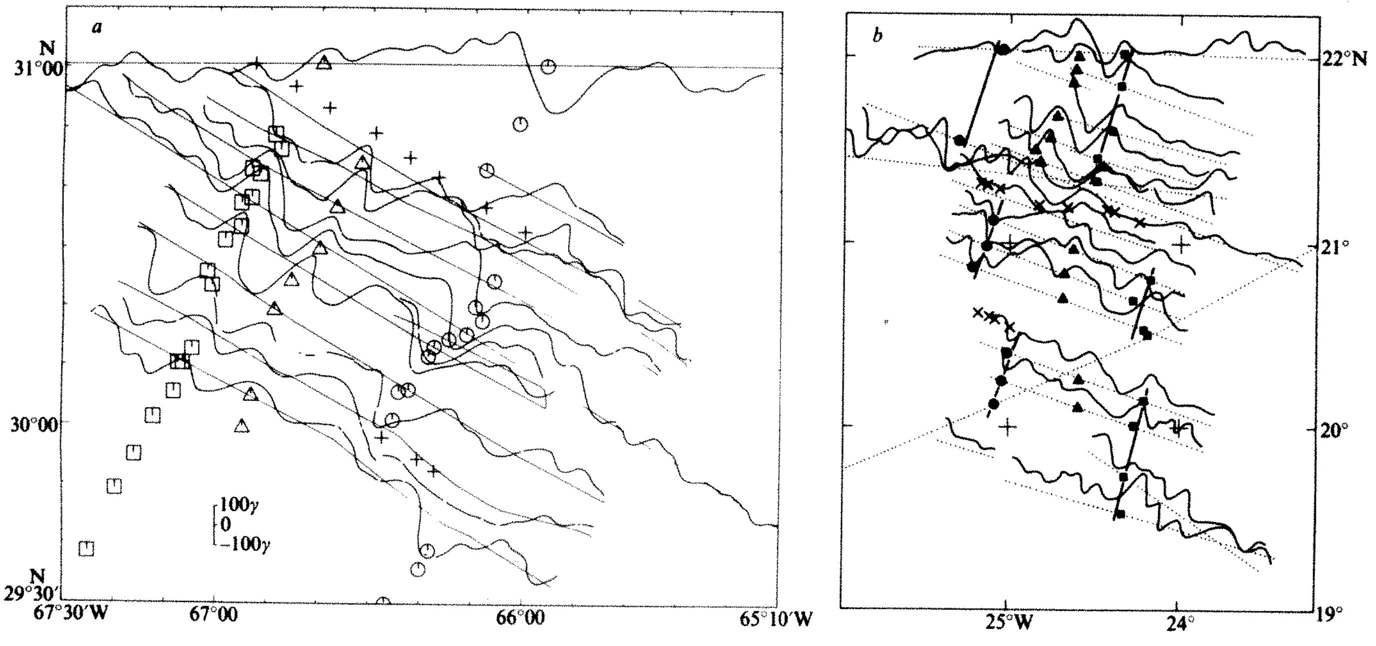

Fig. 2 Magnetic anomalies plotted along track with anomaly positions and fracture zone positions (+, ×) superimposed. *a*, North American plate; *b*, African plate. ●, M0; ▲, M2; ■, M4.

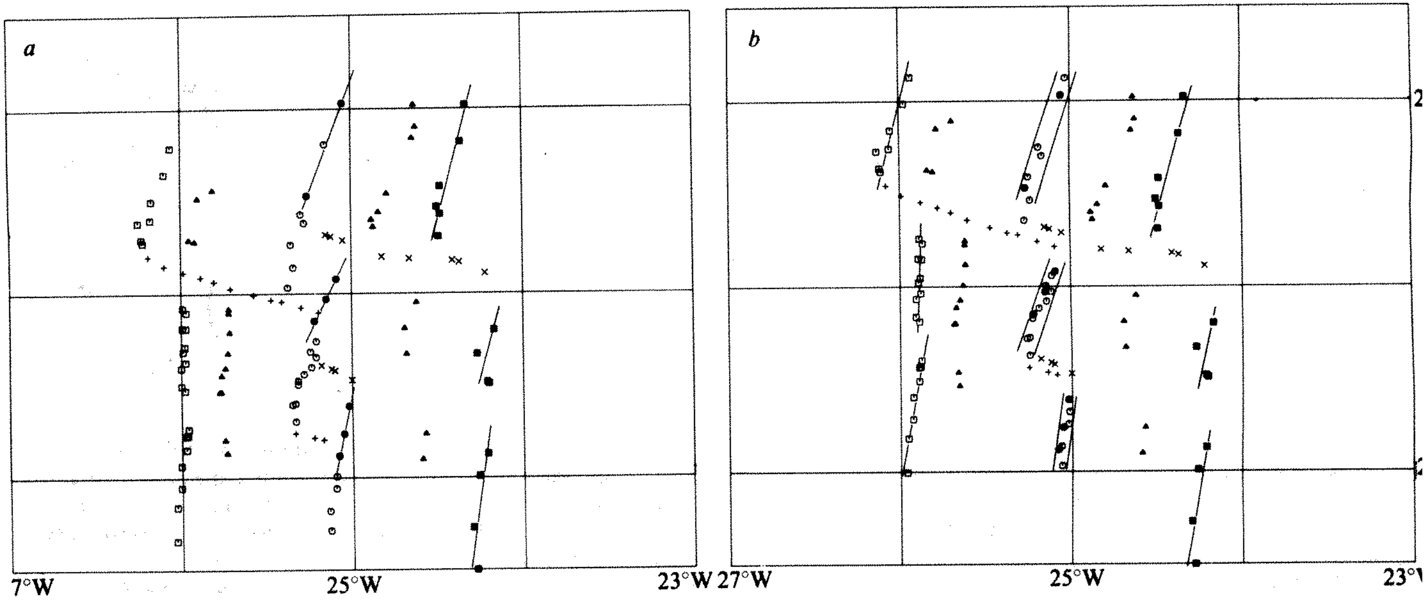

Fig. 3 *a*, Reconstruction of relative plate positions using the initial Schouten and Klitgord pole of rotation for M0. *b*, Reconstruction of relative plate positions using the least squares pole of rotation for M0. ○, M0; △, M2; □, M4.

matched. The data are rotated by a given pole and angle, and a great circle is computed for each segment of the plate boundary by a least squares technique. The closer the data fall on the great circle, the better the fit is considered to be.

Goodness of fit is measured by calculating the distance of a point from its great circle, squaring this quantity, and summing for all data points and all segments. This sum is called the fit measure and is computed for poles and angles within the specified ranges. The pole and angle with the smallest value of the fit measure is considered the best. Points known more accurately are preferentially weighted.

For these computations, magnetic anomalies were assigned an error in location of ±3 km, and transform faults ±10 km. The relative magnitudes of the errors are the important factor in the computations. The position of the transform fault active at a specific time within a fracture zone was considered to be less well constrained than the position of the magnetic anomaly isochrons. Uncertainties in ship navigation and variability in magnetic anomaly shape are such that the error in magnetic anomaly location is probably more realistically estimated as 6 km. Poles of rotation computed using an error of 10 km for the magnetic anomaly positions differed by a few tenths of a degree from those using an error of 3 km.

The data for magnetic anomaly M0 were divided into three ridge segments and two transform fault segments. The pole of rotation which gives the best fitting reconstruction of the M0 plate boundary is 66.78°N, 19.00°W with a rotation angle of 53.75° (Fig. 3*b*). We will call this the 'least squares pole'. The pole calculated from a visual reconstruction of M0 is 66.71°N, 19.25°W with a rotation angle of 53.85° (reconstruction not shown). (We call this the 'visual pole'.) In the visual fit fracture zone positions were made to be more coincident than on the rotation by the least squares pole. This condition is not necessarily valid as the North American transform fault positions were picked from magnetic anomalies and the African from seismic reflection profiles. The actual pole positions, however, are almost identical.

The M0 least squares pole of rotation and its contoured fit measure have been plotted (Fig. 4) along with the positions of the visual pole and the initial Schouten and Klitgord pole of rotation. The smallest fit measure for each pole on a 1° grid was plotted and contoured. A trough strikes roughly north-east–south-west containing poles with a low value of the fit measure, that is, poles that give 'good' or statistically acceptable fits. The 'best' pole lies within a local minimum.

Data for M4 were treated similarly (Table 1).

The poles calculated from the detailed data set for M0 and M4 by the least squares technique and the visual techniques are within $\frac{1}{2}$° or 1° of each other. The least squares techniques has the advantage of allowing a computation of the fit measure, a numerical description of how good each computed reconstruction is.

Both poles as calculated only from the detailed data sets were applied to the regional data and gave good fits for the whole ocean basin. The least squares pole gave a better fit than the visual pole. As a study of the fit of 2° of plate boundary has given a good description of the fit of 23° of plate boundary, the two plates must have behaved with a high degree of rigidity.

Schouten and Klitgord have since considered the detailed data and recomputed the M0 pole which also fits the regional

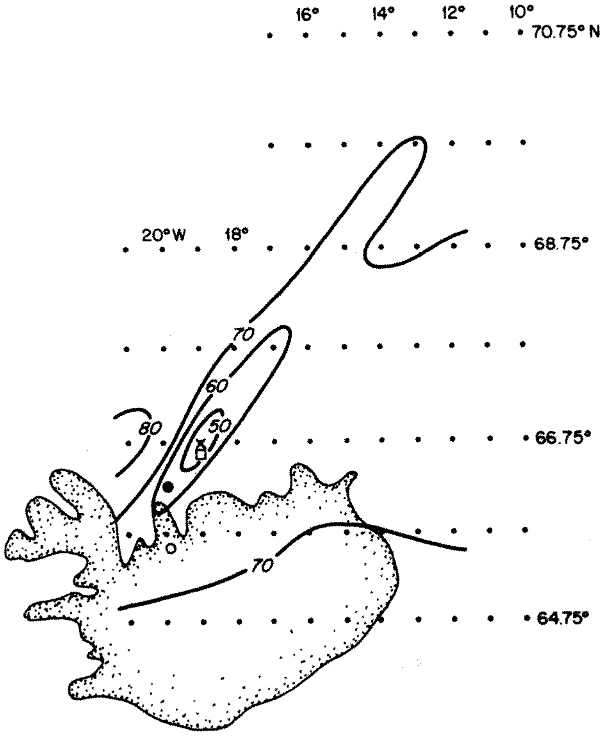

Fig. 4 Measure of fit for M0. The initial Schouten and Klitgord (○), the least squares (×), the visual (□), and the refined Schouten and Klitgord (●), pole of rotation positions have been plotted.

Table 1 Poles of rotation

	M0			M4		
	Lat	Long	Rotation angle	Lat	Long	Rotation angle
Initial Schouten and Klitgord	65.6	−19.9	54.71	65.3	−19.6	57.18
Least squares	66.75	−19.00	53.78	65.25	−21.00	57.55
Visual	66.71	−19.25	53.85	64.74	−21.55	58.11
Refined Schouten and Klitgord	66.3	−19.9	54.37	66.1	−19.0	56.40

magnetic data. This 'refined pole of rotation' lies 1° south-west of the least squares pole; it gives a statistically and visually satisfactory fit for the detailed data set. This suggests that poles of rotation based on widely scattered data can be improved by studies of small areas with a dense data coverage. This study further shows that in regions of sparse data, poles of rotation may be reliably calculated from detailed surveys of small areas of complementary crust.

We thank the captain and crew of the MV Tyro; H. Schouten and M. Purdy for their reviews, and J. Bear and D. Allison for their patience and typing. We especially thank Dr B. J. Colette who conducted the survey on the MV Tyro. Financial support came from the Netherlands Organization for the Advancement of Pure Research (ZWO) and the NSF (contract OCE78-25644). K. R. received support from the Woods Hole Oceanographic Institution, Department of Education.

Is a black coat in the desert a means of saving metabolic energy?

Razi Dmi'el, Avi Prevulotzky & Amiram Shkolnik

Department of Zoology, The George S. Wise Faculty of Life Sciences, Tel Aviv University, Tel Aviv, Israel

Black goats of small body size (15–22 kg) dominate the herds of the Bedouins inhabiting the extreme deserts of the Middle East[1]; only a few white goats appear in such herds. Annual rainfall in these deserts varies from 15 to less than 150 mm; resources of food are sparse and watering points widely spaced. Summer is extremely hot and winter may be bitterly cold. Cloudy days are rare and solar radiation is immense all the year round[2]. Presumably, special adaptations would have been required in order to thrive in these harsh deserts. Can the black colour of the Bedouin goat be considered such an adaptation? Here, we have attempted to answer this question, and have found that by absorbing more of the Sun's energy on cold days, the temperature of the coat dramatically increased and the goat's oxygen consumption decreased significantly.

Short-wave radiation has been shown experimentally to penetrate animal coats by multiple diffuse reflection. For white coats, short-wave radiation may be scattered into the coat and absorbed below the surface, facilitating the inward flow of heat to the skin. For black coats, short-wave radiation is absorbed near or at the fur surface; little is reflected but a large amount is re-radiated as long-wave radiation before it reaches the skin[3,4].

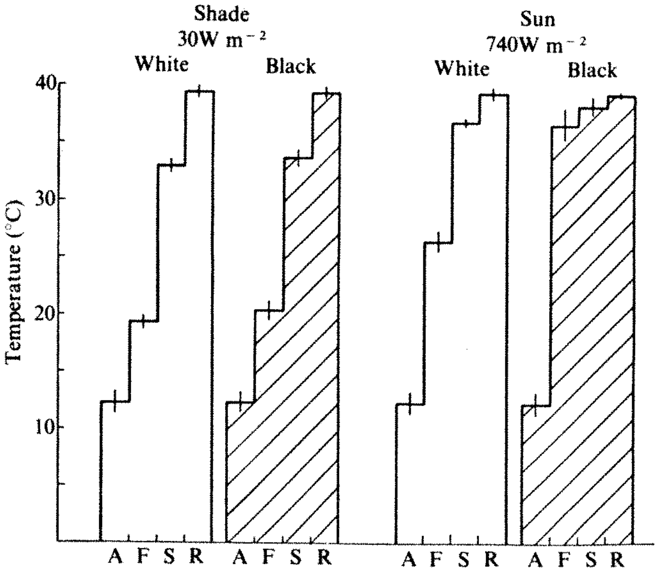

Fig. 1 Ambient and body temperature of two black and two white Bedouin goats, as measured during a clear winter day in the desert. Experimental time 0930 to 1430 h. Values are mean ± s.e. (vertical bars) of 35 measurements. A, Air; F, coat; S, skin; R, rectal.

This suggests that the black coat may thus reduce the heat gain and the need for evaporative cooling. However, recent studies have negated this possibility. It has been shown that the black goat absorbs about 80% of the solar radiation impinging on its fur and evaporates appreciable amounts of water, mainly through its skin[5–7]. In contrast, white goats absorb only 40% of the impinging radiation, and, consequently, evaporate much less water[6]. Black colour in the Bedouin goats is therefore not advantageous during the hot desert summer. The purpose of the present study was to determine whether their black coat enables the goats to improve their energy balance during the desert winter, when energy demands of the goat are high but food availability is at a minimum[8].

To assess the contribution of coat colour to the energy economy of the goats, we set out to answer two questions: (1) what is the effect of solar radiation on body temperatures and metabolism of Bedouin goats during a typical winter day in the desert, and (2) is this effect the same in black and white goats? Experiments were carried out during the winters (mid-December to mid-February) of 1976–8 in the mountainous region of the Sinai Desert. Two black, mature females (18.5 kg body weight) were purchased from local Bedouins. To ensure acclimatisation, they remained in their original herd for the entire year, except for the experimental period (12 measurement days altogether), when they were taken to the nearby study area. In addition, two local white goats were studied. They were also kept in the same herd as the black ones. Oxygen consumption, rectal, coat surface and skin temperatures of the goats were measured simultaneously, as the goats stood quietly either fully

Table 1 Oxygen consumption of black and white Bedouin goats during a clear winter day in the desert

	Oxygen consumption ($ml\ O_2$ per kg per h) Shade	Sun	Metabolic reduction (%)
Black goat	488 ±20	351 ±28	28.1
White goat	488 ±18	436 ±17	10.7

Values are mean ± s.e. of 35 measurements. Radiation in the shade 30 W m^{-2}, radiation in the Sun 740 W m^{-2}. Air temperature in both experimental conditions was 12.2 °C.

exposed to the Sun or in the shade. The techniques and their accuracies were the same as those described in detail elsewhere[5,6], except that in the present study the animal and air temperatures were measured by fine (36-g) copper–constantan thermocouples. The measurements were made between 0930 and 1430 h, when air temperature (mean 12.2 °C, s.d. 3.5 °C) and solar radiation (mean 740 W m^{-2}, s.d. 95 W m^{-2}) were fairly stable. All the measurements were made over 30-min intervals; a period of 45–60 min was allowed to ensure thermal equilibrium before each experiment.

No difference in either body temperature or metabolic rate was found between black and white goats as long as they stood in the shade. However, when exposed to the Sun, the coat and skin temperatures of both black and white goats increased and their metabolic rate decreased. These changes were far greater in the black goats (Fig. 1, Table 1). As air temperature was the same in both Sun and shade, it is clear that the change in oxygen consumption depends on the change of the gradient between core body to coat surface temperature. The change in oxygen consumption per degree of temperature change is much the same in both goats (Table 2). This indicates that the differently coloured coats have similar insulative characteristics. Therefore, the larger metabolic reduction shown by the black goat is due to a greater change in its coat surface temperature, resulting from a higher absorption of the solar radiation.

To assess the role of black colour in a desert animal, one should take into consideration the entire climatic cycle to which the animal in question is exposed. We propose here that the critical season of the year for the Bedouin goat is the relatively short, cold desert winter and not the hot, dry summer. Presumably, water is not the crucial selection factor, because this breed is equipped with specialised physiological mechanisms which enable the goat to withstand prolonged periods of water deprivation[9,10]. On the other hand, these goats are not equipped with efficient mechanisms to prevent heat losses when exposed to cold. The loose and shaggy coat of the goat is a poor insulator. This is reflected in the rather high, lower critical temperature (26 °C) obtained for this breed[9]. Therefore, to keep its body temperature constant during cold weather, the goat must rely mostly on metabolic energy rather than on insulation. The reduction in metabolic rate, associated with absorption of more solar radiation by the black coat, can therefore be regarded as a mechanism which may be critical for the goat's survival during periods of food scarcity in winter. It is reasonable to assume, therefore, that selection pressure for survival of the Bedouin goat in the desert has centred on energy economy rather than water economy. The finding that black goats need less energy provides a logical explanation for the seeming paradox that the Bedouins have selected black animals for their milk and meat producers in hot deserts.

Black robes of goat's hair are commonly worn by Bedouins in the desert. A recent study carried out during the hot desert summer has demonstrated that the effect of a black robe on the heat balance of man is the same as the effect of a white one[11]. However, in the light of our measurements, it would be interesting to determine whether during winter in the desert, the black robe has a role similar to that we assign to the black fur of the goat.

This research was supported by a grant from the United States–Israel Binational Science Foundation (BSF), Jerusalem, Israel. We thank the members of 'Tzukay David' Field School for their hospitality and Mr David Levanon for his assistance in the field experiments.

Role of the surface carbohydrates in sperm–egg interaction in *Ciona intestinalis*

Floriana Rosati & Rosaria De Santis

Stazione Zoologica, 80121 Napoli, Italy

In the ascidian *Ciona intestinalis*, species-specific recognition and binding between spermatozoa and eggs occurs at the outer surface of the vitelline coat (the chorion). Attachment of spermatozoa to the chorion occurs via very thin, Ruthenium red-positive fibrils connecting the plasma membrane of the tip of the spermatozoon with the fibrillar tufts of the outer surface of the chorion[1]. Experiments with fluorescein-conjugated lectins suggest that glucose or mannose and fucose residues are exposed at the surface both of the chorion and of the spermatozoon, while *N*-acetyl-glucosamine is only present at the surface of the chorion[2]. Work presently underway shows that the prevailing sugar components of the chorion are fucose, glucose and *N*-acetyl-galactosamine. However, this last sugar does not seem to be exposed at the surface of the chorion[2]. The role of the sugar residues exposed at the surfaces of the chorion and spermatozoon in gamete recognition and binding has been investigated to determine whether these sugars are functional components of the gamete receptors. It would be expected that binding of the spermatozoa to the chorion and fertilisation should be competitively inhibited in the presence of excess fucose, glucose and/or mannose, while *N*-acetyl-galactosamine and *N*-acetyl-glucosamine should not be effective. Our present results suggest that fucose residues play a key part in the binding reaction and in fertilisation.

For a quantitative estimate of the binding reaction we have used 'glycerol-treated' eggs (ref. 3). We have previously shown[1,3] that treatment of unfertilised eggs with glycerol does not impair the species-specific binding of the spermatozoa to the chorion. However, in these conditions the spermatozoa fail to undergo the acrosome reaction. This has allowed us to dissect out the events of sperm attachment from those of the acrosome reaction and sperm penetration through the chorion[1].

For a quantitative study of the effect of the various sugars on gamete interaction we have used the subtraction method of Vacquier and Payne[4]. The sperm concentration is linearly related to absorbance at 340 nm. The binding was routinely checked in the light microscope under dark field illumination[3]; this showed uniform distribution of spermatozoa attached to the eggs at all sperm concentrations used. The maximum number of spermatozoa attached to eggs occur between 3 and 6 min after 'insemination' (Fig. 1). The maximum percentage of bound spermatozoa is between 20 and 40% depending on the concentration of free spermatozoa. By varying the concentration of

0028-0836/80/080762—03$01.00

sperm available per egg, the maximum number of bound spermatozoa can be seen to be reached at a ratio of about 8×10^3 spermatozoa per egg (Fig. 2); in these conditions the estimated number of spermatozoa bound to each egg is about 2,500–3,000. This ratio was used in experiments of competitive inhibition with the sugars.

Preliminary experiments also showed that none of the sugars tested, even at the highest concentrations affect either sperm motility or oxygen uptake (Yasumasu, personal communication). However, the effect of these sugars is completely reversible. The effect of the different sugars on the binding reaction is shown in Fig. 3. Of the sugars tested, L-fucose is proved to be the only one which effectively competed with the binding of the spermatozoa to the chorion. The L-fucose concentration required for maximum inhibition is 50 mM; at 25 mM inhibition is approximately halved; at 10 mM this sugar is completely ineffective. These concentrations may, at a first glance, seem high. However one should consider that at the site of contact between spermatozoon and the receptors on the chorion the concentration of the sugar is likely to be very high. Similarly the interaction between lectins and their receptors is inhibited only at high sugar–lectin ratios.

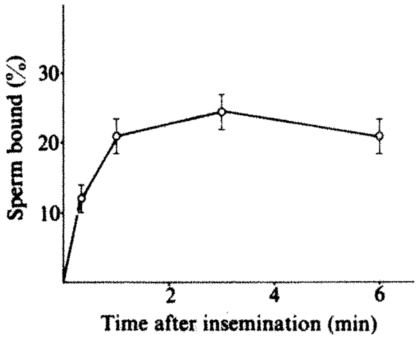

Fig. 1 Samples, each 1 ml, of a 5% suspension of glycerol-treated eggs (corresponding to 5×10^3 eggs) were 'inseminated' in small beakers with 1 ml of sperm suspension at a concentration of about 3.5×10^3 sperm available per egg. At the times indicated, 2 ml of 2% glutaraldehyde in sea water was added (which caused the eggs to sink rapidly to the bottom of the beaker). The absorbance of the supernatant (unbound spermatozoa) was then measured. The number of bound spermatozoa was calculated as the difference between the unbound and the total number of spermatozoa in the original suspension. The mean and standard deviations are calculated from four experiments.

A puzzling observation for which we have no explanation is that when fucose-treated eggs were checked under the microscope there was always about 10% of the eggs whose chorion was covered by attached spermatozoa (those which were not removed by repeated washing[3]), while the remainder did not have any attached spermatozoa at all. Even though the percentage of these eggs is small it is nevertheless bound to lower the value of the overall effect of fucose on sperm binding. When D-fucose, the uncommon isomer of L-fucose was tested under the same conditions, no effect whatsoever was observed. The results with glucose were variable; in some experiments the inhibition of binding ranged from 60 to 80% while in other experiments there was no effect. Figure 3 also shows that mannose, N-acetyl-glucosamine and N-acetyl-galactosamine have no inhibitory effect. The effect of galactose, although not present either in the chorion or in the sperm plasma membrane was also tested and proved to be completely ineffective.

We have also tested the effect of saccharides on fertilisation. In each experiment samples of 100 eggs from the same animal were suspended in the same concentrations of sugars used for inhibition of binding experiments. After 30 min of incubation the same amount of sperm (2–6×10^5 spermatozoa ml^{-1}) was added and 1 h later the eggs were checked for cleavage. The inhibitory effect of the L-fucose on the fertilisation response was proportional to the sugar concentration. In 15 experiments out of 18, 100% inhibition was observed at the highest concentration (50 mM) while at the lowest one (10 mM) there was no difference with respect to the controls. The inhibition ranged from 20 to 50% when the sugar concentration was 25 mM. The effect of glucose was again variable; in the majority of experiments from 40 to 100% of eggs were fertilised while in a few cases none were fertilised. The other sugars tested (mannose, galactose, N-acetylgalactosamine and N-acetylglucosamine) were totally ineffective. The effect of fucose is reversible; indeed binding and fertilisation occur normally when eggs incubated in fucose are then washed and inseminated. In another series of experiments, living eggs were inseminated in the presence of L-fucose; an aliquot was transferred to a dialysis tube and dialysed against sea water for 1 h. The eggs recovered from the dialysis tube proved to be fertilised while the undialysed controls did not cleave. The effect of fucosidase as well as of other glycosidases is now being tested.

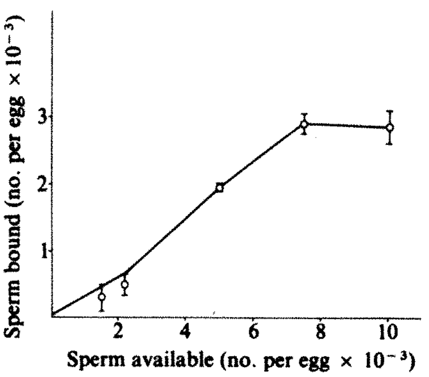

Fig. 2 Experimental conditions were as for Fig. 1. A constant number of eggs (5×10^3 ml^{-1}) was exposed to different concentrations of spermatozoa for 6 min, whereby the final sperm egg ratio (sperm available per egg) ranged 1.7–10×10^3. The mean and standard deviations are calculated from four experiments.

The results described here strongly suggest that L-fucose residues present on the plasma membrane of the spermatozoon and/or on the outer surface of the chorion are functionally involved in the recognition between spermatozoa and eggs. Interpretation of the molecular mechanisms involved must await further work. However in view of the presence of the same sugar residues both on the surface of the chorion and on the plasma membrane of the spermatozoon (as suggested by our

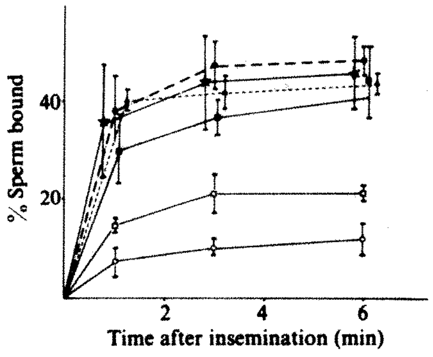

Fig. 3 Eggs (5×10^3 ml^{-1}) and spermatozoa (8–9×10^3 available per egg) were each suspended in sea water containing the sugar at a final concentration of 50 mM (unless otherwise indicated). The two suspensions were then mixed and the results checked at the time indicated in the abscissa. Fucose was additionally used at 25 mM concentration. In each experiment all sugars were tested and control experiments were performed using eggs and spermatozoa from the same stock. (All sugars tested were from Sigma.) The mean and standard deviations are calculated from six experiments. Control (●); fucose (○); fucose 25 mM (□); mannose (▲); N-acetyl-glucosamine (★); N-acetyl-galactosamine (■).

previous work[2]) a possible model might be the one proposed by Cook[5] for carbohydrate–carbohydrate interactions in all hydrated phase-containing carbohydrates and Ca^{2+}. The model is based on the observation that fucose and, in fact any uncharged sugar can form sugar–$CaBr_2$ complexes in which Ca^{2+} is bound to two symmetry-related sugar molecules and to three water molecules, thus resulting in the formation of hydrated fucose–Ca^{2+}–fucose bridges.

Ca^{2+}-dependent hormonal stimulation of ciliary activity

Pedro Verdugo

Center for Bioengineering and Department of Biological Structure, University of Washington, Seattle, Washington 98195

It has been demonstrated that calcium modulates ciliary activity in protozoa[1] and also in epithelial cilia of the mussel gill[2]. Changes in the frequency of ciliary beat in the oviduct of the salamander have also been associated with movement of Ca^{2+} across the cell membrane[3]. However, the control of ciliary activity in mammals is poorly understood and the function of calcium in mammalian cilia and its role in coupling hormonal effects to changes in ciliary activity have been only preliminarily investigated[4]. The evidence presented here suggests that the stimulus–response coupling of the stimulating effect of prostaglandin E_2 (PGE_2) on ciliary activity of the rabbit oviduct is carried out by release of intracellular Ca^{2+}.

To avoid artefacts introduced by uncontrolled changes in the viscosity of epithelial secretions, experiments were conducted in cultures of ciliated cells from the rabbit fimbria. Tissue was grown according to the method of Rumery *et al.*[5] which yields cultures rich in ciliated cells and almost devoid of secretory cells. The animals were pretreated with a single intravenous (i.v.) dose of 100 μg of luteinising hormone administered 10 h before explanting the tissue. A total of 24 cultures of oviductal ciliated cells were grown in Rose chambers containing Eagle's medium (Steinberger modification) with 10% horse serum, *p*H 7.5, and incubated for 36–48 h at 37 °C.

Ciliary activity was monitored by laser light-scattering spectroscopy. A description of the application and validation of this method in comparison with the measurement of ciliary motion by high-speed cinematography has been published elsewhere[6].

The cultured cells were first equilibrated in Hanks' solution, *p*H 7.3 at 37 °C for 30 min. The Rose chambers were then positioned in a Reichert inverted microscope modified for laser scattering spectroscopy. The attenuated and collimated beam of a Spectra Physics 124A He–Ne laser was directed at the culture chamber illuminating an area of approximately 8,000 μm^2 containing about 10,000 cilia. The laser light scattered by the moving cilia was collected by the objective lens of the microscope at an angle of 35° from the plane of the chamber. The changes in intensity of the scattered light were detected as current fluctuations by a photomultiplier tube (RCA-C7164R). The spectrum of the photocurrent fluctuations which directly gives the statistical distribution of frequencies of ciliary beat (see Fig. 1 inset), was processed on-line by a fast Fourier transform digital spectrum analyser developed in our own laboratory.

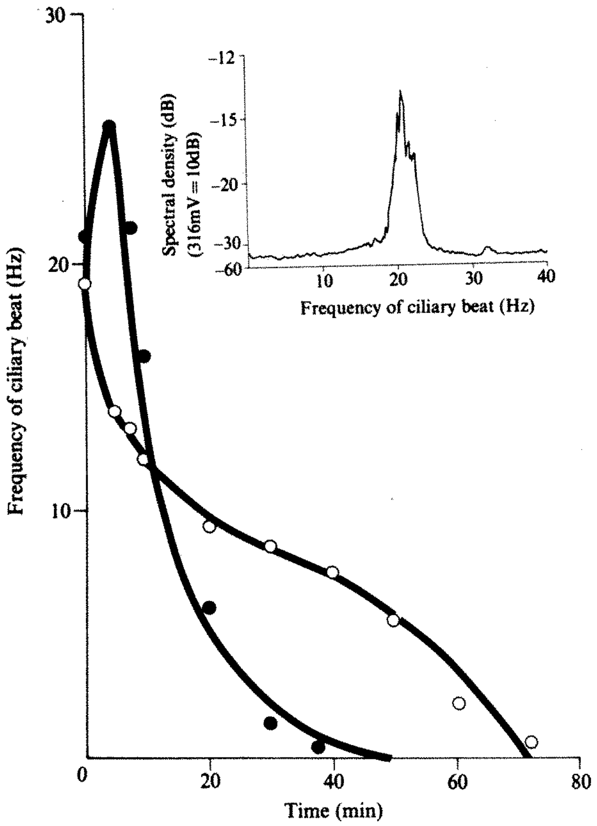

Fig. 1 Typical time course of the effect of decalcification on the frequency of beat of ciliated cells from the rabbit oviduct in tissue cultures. At time zero the cultures were perfused with Ca-free Hanks' solution containing 2 mM EGTA with (●) or without (○) PGE_2 (10^{-7} M). Note the initial increase followed by an exponential decrease in the frequency of ciliary beat produced by PGE_2. Inset shows the spectrum of ciliary beat obtained by laser scattering spectroscopy. Note the presence of a single dominant peak centred at a frequency of 21 Hz.

The cultures were first scanned to find clusters of ciliated cells demonstrating a stable and narrow peak of ciliary beat frequencies for at least 30 min. Following this control period, the Rose chamber was perfused with 10 ml of Ca-free Hanks' solution containing 2 mM EGTA. The frequency of ciliary beat was monitored for the next 60–80 min until ciliary arrest was observed (Fig. 1). The cultures were then re-equilibrated in Hanks' solution containing EGTA-buffered calcium concentrations of either 10^{-6}, 10^{-5}, or 10^{-3} M Ca^{2+} (6 cultures at each concentration). Aftef ~10 min the frequency of ciliary beat had increased to a new stable level which, in the case of the Hanks' solution containing 10^{-3} M Ca^{2+}, was approximately similar to the initial control. At this time the dose–effect relationship of PGE_2 (Upjohn) on the frequency of ciliary beat was investigated in each group of cultures by increasing the level of the prostaglandin in the Rose chambers while maintaining constant the correspondent calcium concentration (Fig. 2).

In a different set of experiments three cultures were decalcified in Ca-free Hanks' with 2 mM EGTA but in the presence of 10^{-8} M PGE_2 (Fig. 1). Finally in three other cultures PGE_2 was introduced into the Rose chamber after ciliary activity had been arrested by decalcification in Ca-free 2 mM EGTA Hanks' solution.

As observed in our preliminary investigations[7], the frequency of ciliary beat in mammalian ciliated cells can be reversibly modified by changing the extracellular Ca^{2+} concentration. However, the present experiments indicate that the stimulation of oviductal cilia by PGE_2 is fairly independent of calcium concentration in the medium. Note that in Fig. 2, especially at PGE_2 concentrations higher than 10^{-7} M, the rate of ciliary beat increases to a maximum and demonstrates no statistical difference over a rather wide range of Ca^{2+} concentrations.

The infusion of Ca-free Hanks' solution containing 2 mM EGTA in the Rose culture chamber produces a consistent

0028-0836/80/080764—02$01.00

biphasic time-dependent decrease of the frequency of ciliary beat (open circles in Fig. 1). However, when this same experiment is performed in the presence of 10^{-7} M PGE_2, the frequency of cilia beat shows a transient increase followed by an exponential decrease that results in the arrest of ciliary activity within approximately 40 min (solid circles in Fig. 1). This effect mimics that produced by the Ca ionophore, A23187, in cultures of ciliated cells of the rabbit trachea and oviduct[7].

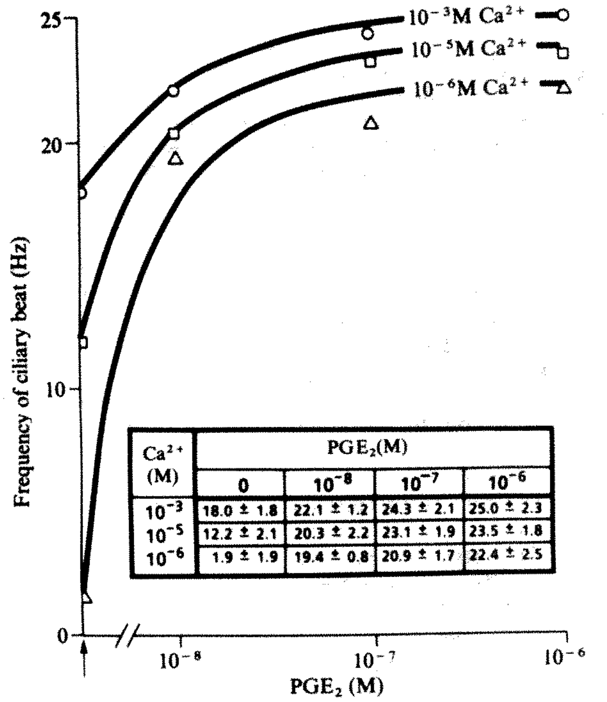
When PGE_2 at 10^{-7} M concentration is introduced into the culture chamber after ciliary activity has been arrested by 2 mM EGTA in Ca-free Hanks', a typical rapid increase followed by a rapid decrease in the frequency of ciliary beat is observed. Further increasing the PGE_2 concentration to 10^{-6} M produces transiently an additional smaller increase in frequency. However, this response could not be elicited again by 10^{-5} M PGE_2.

Calcium has been implicated in excitation–contraction coupling[8] and in coupling the avoiding response of ciliary reversal in protozoa[9] as well as coupling non-motile processes such as stimulus–release of neurotransmitter and endocrine hormones[10]. The present experiments suggest that calcium may also be involved in the stimulus–response coupling of hormonal stimulus to ciliary motions produced by PGE_2. It has been proposed that much of the pharmacology of prostaglandins can be understood on the basis of their facilitation of Ca^{2+} movement across biological membranes[11]. Our data appear to corroborate this idea, suggesting that the stimulation produced by PGE_2 must be associated with the release of intracellular calcium as: (1) the increase in the frequency of ciliary beat produced by PGE_2 is fairly independent of calcium levels in the medium (Fig. 2); (2) although the complex time decay in the frequency of ciliary beat produced by decalcification is not sufficient to support the idea of multi-compartmentalisation of calcium in ciliated cells, the transient increase, followed by an exponential decrease, in ciliary activity observed in the presence of PGE_2 (Fig. 1) is consistent with a prostaglandin-stimulated release of calcium from intracellular compartments; and (3) the transient activation produced by PGE_2 in ciliated cells maintained in Ca-free medium and arrested by calcium-depletion indicate that in these cells there must be a pool of intracellular calcium which can be released by PGE_2 and which may, transiently, stimulate ciliary activity before diffusing to the extracellular space.

The similarity of the effect of PGE_2 to that of the ionophore A23187 (Fig. 1) is not surprising as it has been suggested that prostaglandins may act as a 'calcium ionophore' in subcellular structures[12].

The data presented here are the first indication of calcium-dependent coupling of hormonal stimulus to ciliary activity. They suggest that PGE_2 stimulates ciliary motion by releasing intracellular bound or sequestered calcium, a mechanism that has also been suggested to explain the effect of prostaglandins in other tissues[12].

Prostaglandins have been found in the wall of the oviduct[13] where ciliary actions have been shown to be directly implicated in ovum transport[14]. The present work, therefore, may serve as a model to gain knowledge of the mechanism of action of hormonal influences on ciliary activity and also to understand further the role of prostaglandins in oviductal function.



Ca^{2+} (M)	PGE_2(M)			
	0	10^{-8}	10^{-7}	10^{-6}

An ATP-dependent Ca^{2+}-pumping system in dog heart sarcolemma

Pico Caroni & Ernesto Carafoli

Laboratory of Biochemistry, Swiss Federal Institute of Technology (ETH), 8092 Zurich, Switzerland

Since the pioneering studies of Ringer of almost a century ago[1,2], it has been known that the contraction of heart cells requires the presence of calcium in the extracellular medium. Ca^{2+} penetrates into the sarcoplasm where it either directly activates troponin C (ref. 3), or indirectly conveys the contraction signal to the myofibrils, possibly by inducing Ca^{2+} release from intracellular stores (sarcoplasmic reticulum, SR)[4–6]. After contraction Ca^{2+} must obviously leave the heart cell again to prevent its progressive accumulation. As the electrochemical potential of Ca^{2+} across the sarcolemma would prevent its passive outflow, the efflux of Ca^{2+} is an energy requiring process. Most of the Ca^{2+} is apparently ejected from heart cells in exchange for Na^+ (refs 7, 8), on an electrophoretic antiporter which exchanges three Na^+ ions for one Ca^{2+} (ref. 9). However, there is some evidence[10–14] of a specific ATPase in cardiac sarcolemma, which could also have a role in the energy-dependent ejection of Ca^{2+}. One important difficulty in trying to establish the existence of a specific Ca^{2+}-ATPase in cardiac sarcolemma lies in the fact that most of the preparations used in such studies have been heavily contaminated by other subcellular fractions (mitochondria, SR) which also possess ATP-dependent Ca^{2+} transporting systems. In the present work we describe an ATP-dependent Ca^{2+} transport system which can be conclusively ascribed to heart sarcolemma. We show that a heart vesicular preparation particularly enriched in sarcolemma markers accumulates Ca^{2+} in the presence of ATP. That the process takes place in sarcolemmal vesicles is demonstrated by the fact that the accumulated Ca^{2+} is promptly and completely released in exchange for Na^+.

0028–0836/80/080765—03$01.00

Sarcolemmal vesicles from dog heart were prepared using a method slightly modified from that of Jones *et al.*[15]. The final pellet was washed twice and resuspended in 160 mM KCl, 20 mM HEPES *p*H 7.4 (K-medium), or, when required, in 160 mM NaCl, 20 mM HEPES *p*H 7.4 (Na-medium). Experiments on Na^+/Ca^{2+} exchange were carried out as described by Reeves and Sutko[8]. The $(Na^+ + K^+)$ATPase was measured after unmasking the total activity with Na-SDS[15]. The Ca^{2+}-ATPase was measured as described in ref. 15, in the presence of 20 μg oligomycin per mg protein. Each experiment described has been performed at least four times, with at least three different sarcolemmal preparations. The Na^+ content of the suspensions was determined by atomic absorption spectroscopy, and the protein content using a modification of the method of Lowry *et al.*[16].

The preparation used in the present work is very highly enriched in sarcolemmal vesicles, with specific activities of $(Na^+ + K^+)$ATPase varying between 80 and 105 μmol of phosphate liberated per mg of protein per h. The preparation accumulates Ca^{2+} at the expense of a transmembrane Na^+ gradient[8], 80% of the uptake (60 nmol per mg protein) taking place within the first 10 s. The sarcolemmal vesicles, however, also hydrolyse ATP in the presence of both Ca^{2+} and Mg^{2+}, with a specific activity of 8.5 μmol per mg protein per h. Concomitant with the hydrolysis of ATP, the vesicles accumulate Ca^{2+}, to a maximal level, in the experimental conditions used, of 46 nmol per mg of protein in 10 min (Fig. 1). The apparent K_m of this Ca^{2+} transport system lies between 0.2 and 0.6 μM.

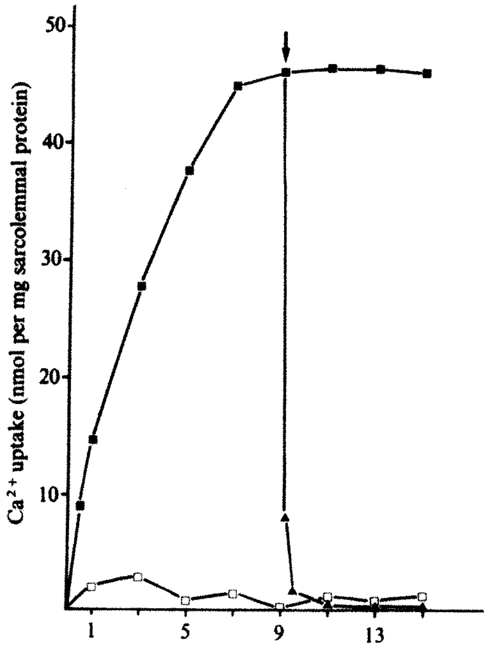

Fig. 1 ATP and Mg^{2+}-dependent Ca^{2+} uptake in dog heart sarcolemma. Sarcolemmal vesicles (20 μg of protein suspended in K-medium) were preincubated at 37 °C in 2 ml of a medium containing 160 mM KCl, 20 mM HEPES, 1 μg oligomycin, 5 mM $MgCl_2$, 1 mM ouabain *p*H 7.4. After 5 min, 150 nmol $^{45}CaCl_2$ were added: 2 min later, the first aliquot was withdrawn, and immediately after (time zero) 1 mM K_2ATP (final concentration) was added. Further aliquots (100 μl) were withdrawn at the times indicated, immediately filtered through Millipore filters (pore diameter 0.22 μm) and washed with 1 ml of ice-cold K-medium, containing 1 mM $LaCl_3$, to avoid Ca^{2+} movements during the 15-s filtration time. The values are corrected for the Ca^{2+} found associated to the sarcolemma before the addition of ATP (average, 28 nmol per mg of protein). The experiments were carried out at 37 °C. In none of the experiments was more than 20% of the total ATP added consumed. ■, No supplementary additions; ▲, at the arrow the ionophore A23187 (final concentration 5 μM) was added; □, no ATP or no Mg^{2+}.

Since two other membrane systems in heart—the mitochondria and SR—accumulate Ca^{2+} in the presence of ATP, appropriate controls were carried out. The possibility of the involvement of the mitochondrial system can be excluded, since oligomycin (20 μg per mg protein, an amount in great excess of that necessary to inhibit completely the ATP-dependent Ca^{2+} transport in mitochondria) and the uncoupler FCCP (1 μM) do not affect Ca^{2+} accumulation in sarcolemmal vesicles. Oxalate at 0.1 to 5 mM also had no effect, making the contribution of SR unlikely. Figure 1 also shows that Ca^{2+} is indeed accumulated into the inner vesicular space, and not superficially bound. The Ca^{2+}-specific ionophore A23187 discharges the accumulated Ca^{2+} completely and very rapidly. Also of interest is the observation that the accumulation of Ca^{2+} requires the presence of Mg^{2+} in the medium.

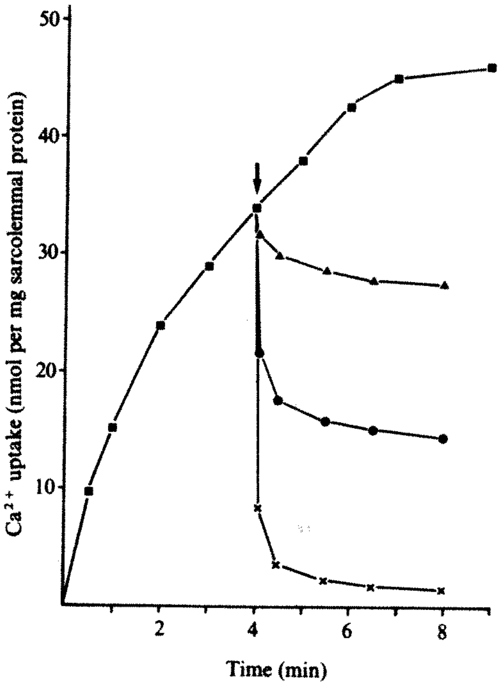

Fig. 2 Na^+-induced release of the Ca^{2+} accumulated by dog sarcolemma in the presence of ATP. Experimental conditions as in Fig. 1, except for the addition (at the arrow) of NaCl (or KCl) to give the final concentrations indicated below. ■, No additions, or 30 mM KCl, or 5 mM NaCl; ▲, 10 mM NaCl; ●, 20 mM NaCl; ×, 30 mM NaCl.

The sarcolemmal preparation used in the present experiments was derived from an oxalate-treated microsomal fraction. The possibility therefore existed that some oxalate could still be associated with SR vesicles contaminating the sarcolemmal preparation. Thus the ATP-dependent uptake of Ca^{2+} could be due, totally or in part, to the SR vesicles: the experiment shown in Fig. 2 rules out this possibility. The SR does not possess a Na^+/Ca^{2+} exchange system. However, the addition of Na^+ to the medium, after the vesicles have taken up about 35 nmol of Ca^{2+} per mg of protein, rapidly discharges the accumulated Ca^{2+}. The discharge is only partial at 10 mM added Na^+, but complete at 30 mM. Ionic strength and osmolarity effects are ruled out by the lack of effect of 30 mM KCl, demonstrating that the Ca^{2+} releasing effect of Na^+ is specific. It is clear, then, that the system under study is constituted by (sarcolemmal) vesicles into which an ATP and Mg^{2+}-dependent system pumps Ca^{2+}, and from which Na^+ specifically releases it.

One more possibility had to be ruled out before concluding that the sarcolemmal vesicles possess a Ca^{2+} transporting system that depends directly on the hydrolysis of ATP. Since it is to be expected that a considerable fraction of the vesicles used in this study have an inside/out polarity, the $(Na^+ + K^+)$ATPase could in principle have preloaded the sarcolemmal vesicles with Na$^+$, which could then be released in exchange for Ca^{2+} (ref. 9). Addition of large amounts of Na$^+$ could then release the accumulated Ca^{2+} again. Measurements of the Na$^+$ concentration in the outside medium, however, have indicated values below 20 μM, at which no (Na$^+$ + K$^+$)ATPase activity could be detected. In addition, the inclusion of ouabain in the reaction medium (followed by preincubation for 1 h at 15 °C to allow equilibration of the inhibitor across the vesicle membrane) had no effect on the observed movements of Ca^{2+} in the experimental conditions used. Finally, the inclusion in the medium of Na$^+$ concentrations increasing from 100 μM to 1 mM (lower than those necessary to observe any release of the accumulated Ca^{2+}, but already adequate to sustain a certain level of (Na$^+$ + K$^+$)ATPase activity[17]), failed to increase the uptake of Ca^{2+}. An increase in Ca^{2+} uptake, on the other hand, would have been expected if the accumulation of Ca^{2+} were due to the discharge of a Na$^+$ gradient previously established by the operation of the (Na$^+$ + K$^+$)ATPase. We can therefore conclude that the sarcolemma of heart cells possesses, in parallel with the Na$^+$/Ca^{2+} exchange system, an ATP-dependent system which specifically transports Ca^{2+}. This system seems to have a higher affinity for Ca^{2+} than does the Na$^+$/Ca^{2+} exchange system, but a lower transport rate (Fig. 2). These differences could be of importance in considering the respective roles of the two systems in heart physiology.

Evidence for two populations of excitatory receptors for noradrenaline on arteriolar smooth muscle

G. D. S. Hirst & T. O. Neild

Neuropharmacology Group, Department of Physiology,
Monash University, Clayton, Victoria, Australia 3168

We have recorded the responses of arteriolar smooth muscle cells to iontophoretically applied noradrenaline. Records of both muscle movement and muscle membrane potential were made. We found that two distinct types of response could be detected, depending on the position of the noradrenaline micropipette. One type of response consisted of a localised constriction near the noradrenaline source: this effect could be abolished by the α-antagonist phentolamine and was not associated with a change in arteriolar membrane potential. The other type of response was a depolarisation similar to the excitatory junction potentials (e.j.ps) produced by sympathetic nerve stimulation. These observations suggest that there are two populations of receptors for noradrenaline on arterioles, and could explain the paradoxical failure of α-antagonists to block neuromuscular transmission at some autonomic end organs such as the vas deferens, arteries and arterioles.

Intracellular recordings were made from very short segments of arteriole (~0.25 electrical length constants; for details see refs 1, 2). Both the membrane potential and diameter of the arteriolar segment were monitored, the latter by use of an inverted compound microscope[1] and a video tape recorder. Muscle movements were measured after the end of the experiment by playing back the video signal frame by frame. The use of such short lengths ensured that any membrane potential change occurring in the preparation would be detected by the intracellular recording electrode. This point was checked by impaling the preparation with two independent microelectrodes, one at each end of the segment. Invariably if both recording electrodes detected an e.j.p. following nerve stimulation, passage of current through one electrode caused a change in membrane potential which was detected by the other electrode. With these very short preparations the electrotonic potentials could not be distinguished from those which would result from current injection into a simple resistance/capacitance circuit[2].

The normal response of such preparations to low frequency supramaximal nerve stimulation (0.4 Hz) was the initiation of e.j.ps with mean amplitudes in the range 1.8–12 mV. These potentials did not produce a detectable movement although occasionally an e.j.p. reached threshold and initiated a muscle action potential resulting in constriction of the whole segment. E.j.ps were not reduced in amplitude by either phentolamine mesylate, tolazoline hydrochloride, prasozin hydrochloride or labetalol hydrochloride (each at 1×10^{-6} g ml^{-1}) even at stimulation frequencies as low as 0.1 Hz.

Attempts were made to mimic nerve stimulation by iontophoretic application of noradrenaline from a second microelectrode (noradrenaline 0.5 M, electrode resistance 150–500 MΩ). The most common response to application of a brief pulse of noradrenaline (5–10 ms, 50 nA) was a localised constriction of the arteriole in the region near the iontophoretic pipette (Fig. 1). These responses were not associated with a change in membrane potential. There was no obvious relationship between the separation of the recording electrode and the iontophoretic electrode and the ability to produce localised constriction. In several experiments constriction of the arteriole occurred within a few micrometres of the recording electrode but even this was not accompanied by a change in membrane potential. The responses not associated with a change in membrane potential (Fig. 1) could be abolished by the addition of phentolamine mesylate (1×10^{-6} g ml^{-1}) to the bathing solution.

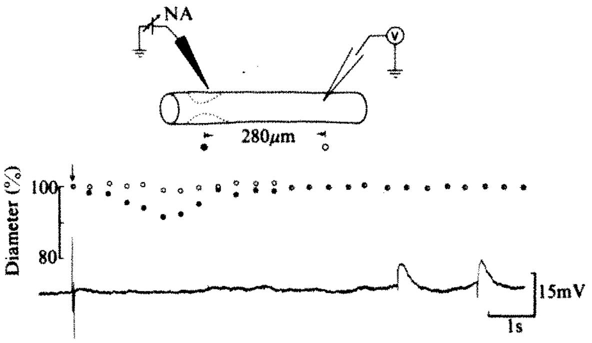

Fig. 1 Effect of iontophoretic application of noradrenaline (NA) on the diameter of an isolated arteriolar segment (upper trace, circles) and on its membrane potential (lower trace). The arteriole had a diameter of 63 μm and a length of 350 μm; after the application of noradrenaline (pulse duration, 10 ms; current, 50 nA at arrow) the arteriole constricted but the constriction was limited to the area near the iontophoretic pipette (●, see experimental sketch). No change in diameter was detected at the position of the recording electrode (○) which was placed some 280 μm further along the arteriolar segment. This response was not associated with a detectable change in membrane potential. At the end of the lower trace, two e.j.ps produced by perivascular nerve stimulation can be seen. These were not associated with a detectable change in arteriolar diameter.

0028-0836/80/080767—02$01.00

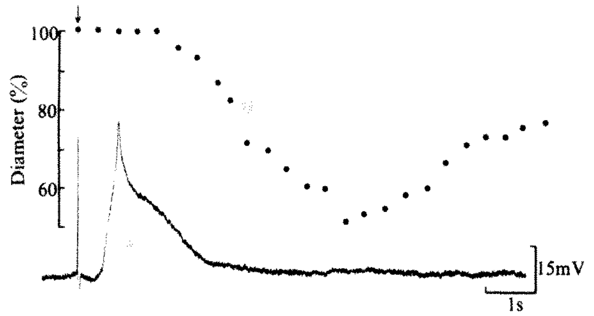

Fig. 2 Effect of iontophoretic application of noradrenaline at a 'reactive area'. A pulse of noradrenaline (duration 10 ms, current 50 nA) produced a depolarisation which initiated an action potential (lower trace), and a generalised constriction of the entire arteriolar segment (upper trace).

On some occasions areas on the arteriolar surface were found where iontophoretically applied noradrenaline produced a depolarisation (Fig. 2). The position of the iontophoretic electrode was critical; in any one experiment some 10–20 trials would be required before an area where noradrenaline caused a depolarisation was found. When this depolarisation initiated an action potential, the entire arteriolar segment constricted (Fig. 2). The delay between the start of the iontophoretic pulse and the onset of depolarisation was highly variable, ranging from <10 ms to 500 ms. Part of this delay is probably due to the difficulty of expelling catecholamines from high resistance microelectrodes because the delay could be shortened by using short high-frequency trains of iontophoretic pulses. Depolarising responses to iontophoretically applied noradrenaline could be detected in the presence of phentolamine (1×10^{-5} g ml^{-1}) but we have not yet been able to rule out the possibility that phentolamine had reduced the amplitude of the depolarisation. During a prolonged intense depolarising response (30–40 mV change in membrane potential) to noradrenaline produced by long iontophoretic pulses (100 ms) e.j.ps could not be detected. This suggests that neuronally released transmitter and applied noradrenaline may initiate conductance changes with similar reversal potentials.

There is an abundance of data to indicate that noradrenaline is synthesised, stored, and released by many sympathetic postganglionic nerve terminals[3]. However, in smooth muscle tissues which receive an excitatory noradrenergic innervation such as arteries, arterioles and vasa deferentia, it has been difficult to explain why responses to exogenously applied noradrenaline differ in some ways from those to nerve stimulation. For example, stimulation of sympathetic nerves innervating the vas deferens produces a two-component contraction, only one component of which is abolished by traditional α-receptor blocking drugs[4]. The contractile response produced by exogeneous noradrenaline can be readily abolished[5]. Noradrenaline causes a contracture of arteries in concentrations which do not produce a change in membrane potential[6]; but e.j.ps not associated with movement, are detected from arterioles and arteries in response to sympathetic nerve stimulation[7,8]. For reasons such as these the role of noradrenaline as the primary transmitter has been questioned[9,10].

We suggest that the difficulty in duplicating responses produced by neuronal stimuli by the application of exogenous noradrenaline arises because the smooth muscle cells have two distinct populations of excitatory receptors for noradrenaline. One group of the receptors which cause membrane depolarisation are the same receptors (junctional receptors) as those which are activated by neuronally released noradrenaline. The other (extrajunctional) receptors have the pharmacological properties of traditional α-receptors. When they are activated, they cause constriction without an associated membrane potential change. In arterioles either the neuronally released transmitter does not have access to extrajunctional receptors or if it does it reaches them in such a low concentration that no contractile responses can be detected (this may not be the case for more densely innervated tissues such as the vas deferens).

These observations are consistent with the view that noradrenaline is a primary transmitter in the sympathetic nervous system. However, responses to sympathetic nerve activity can only be mimicked if noradrenaline is applied to certain restricted areas; the receptors activated at these areas are different from conventional α-receptors which therefore seem to play no part in neuromuscular transmission.

Proprioceptors with central cell bodies in insects

Peter Bräunig & Reinhold Hustert

Fachbereich Biologie, Universität Konstanz, Postfach 5560,
D-7750 Konstanz, FRG

A common feature of invertebrate sense organs is that the cell bodies of the sensory neurones are located in the periphery, close to the site of stimulus reception. For some phyla of invertebrates examples are known where sensory cells have their somata inside the central nervous system (CNS), but none are yet known for the insects. In this report we describe a proprioceptive organ in the locust thorax that consists of an elastic strand that is supplied with terminal branches of a small group of sensory neurones. The somata of these neurones are not located in the periphery, but inside the third thoracic ganglion. Our findings indicate that at least a small number of cell bodies in insect ganglia may belong to sensory neurones, rather than to motoneurones, interneurones or neurosecretory cells.

In locusts the hindlegs are involved in a number of behavioural tasks like stepping, stridulating, kicking, swimming, steering in flight, grooming and help in changing body position. These movements do not follow all-or-nothing programmes imposed by the CNS but are modified in amplitude and duration in response to sensory information especially that from the proprioceptors of the leg itself. Although the proximal joints between thorax, coxa and trochanter of the hindlegs have a major role in whole leg movements, more is known about the more distal joints between femur and tibia and tibia and tarsus[1,2]. We looked for additional internal proprioceptors in the proximal leg joints of the migratory locust (*Locusta migratoria*) by infusing cobaltous solutions distally[3,4] into nerves 2 and 3 of the metathoracic segment. One of the terminal peripheral branches of nerve 3 splits into a meshwork of arborisations on a connective tissue strand between the thorax and the trochantin (Fig. 1) without supplying any detectable somata. This is in contrast to nearby chordotonal organs (for example, cxtnCO in Fig 1). Backfills of these terminal arborisations on the strand show 6–8 neurone somata, 10–15 μm in diameter, in the anterior lateral region of the metathoracic ganglion (Fig. 2). These neurones show rather restricted fields of arborisation compared to locust motoneurones[5].

It seemed possible that this new structure was a degenerating larval muscle, but electron microscopic sections of the strand and terminal nerve arborisations did not show any similarity

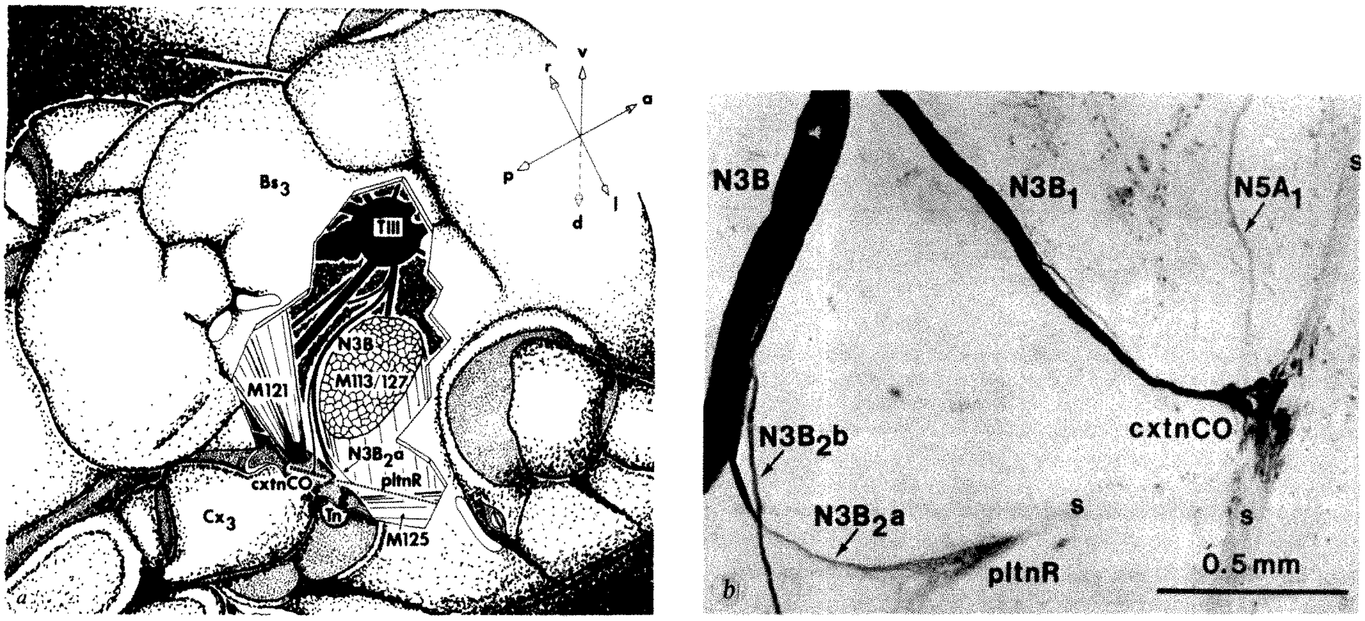

Fig. 1 Morphological features of the pleurotrochantinal receptor (pltnR) in the metathorax. *a*, Ventro-lateral view of the third thoracic segment (metathorax) of the migratory locust. A large window has been cut into the sternal cuticle (Bs_3) and the joint membrane (narrow stipling) of the hindleg coxa (Cx_3). Air sacs and trachea have been removed exposing some muscles (M121, M113/127, and M125) and the metathoracic ganglion (TIII) with all anterior nerve roots except for nerve 2. Two sense organs of the leg joint (cxtnCO, tnplR) are innervated by small branches which emerge from the middle tract of the third nerve root (N3B). a, Anterior; p, posterior; r, right; l, left; v, ventral; d, dorsal; Tn, trochantin. *b*, Peripheral cobalt stain showing branches of nerve 3B. Note the prominent cell bodies in the chordotonal organ (cxtnCO) in contrast to the receptor (pltnR); s, connective tissue strand. The relative position of the two sense organs does not correspond with the natural one in this microscopic wholemount.

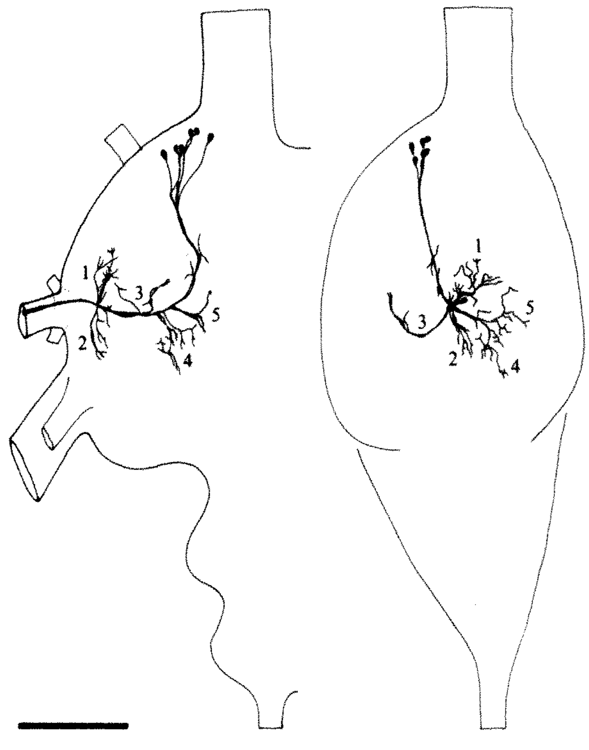

Fig. 2 Cobalt filled and silver intensified central projections in the metathoracic ganglion and somata of six neurones supplying the receptor. Camera lucida drawing of the hemiganglion, viewed dorsally and laterally. Same dendritic areas are indicated with corresponding numbers. Scale bar, 0.2 mm.

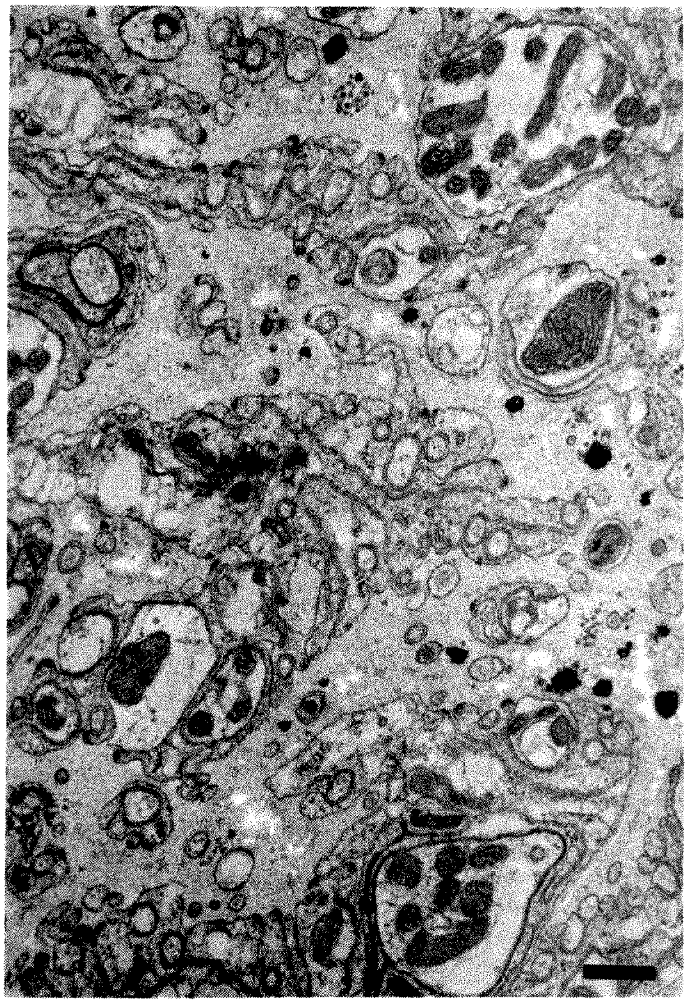

Fig. 3 (right) Electron microscopic cross-section of the receptor strand containing terminal branches of nerve $3B_2a$. Characteristic features: large (for example upper right) nerve profiles, usually surrounded by glia and containing many mitochondria, and small nerve profiles, wrapped in glia or embedded in extracellular material without glial sheath (middle). Scale bar, 0.5 μm.

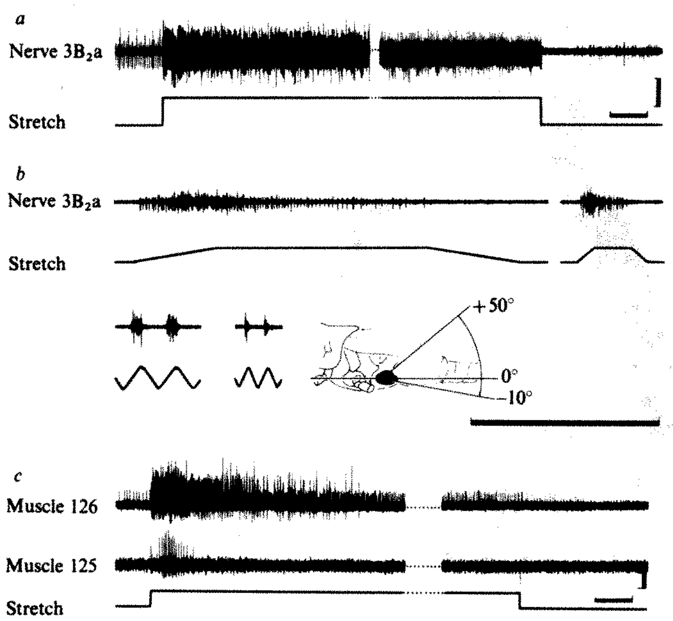

Fig. 4 Afferent and efferent responses to mechanical stimulation of the receptor. *a*, Phasico-tonic afferents (upper trace) after stretching (lower trace) the strand record from distal end of cut nerve $3B_2a$. Note the pronounced off-response. *b*, The effect (upper trace) of slow and fast trapezoid movements (lower traces) applied to the coxa from −10° to +50° as indicated. Range corresponds to normal range in behaviour. *c*, Phasico-tonic reflex response (upper trace) in the motonerve supplying muscles 125 and 126 and phasic response in a myogram of muscle 125 (middle trace) to stimulation of the receptor as in 3*a* (lower trace). Calibrations: horizontal, 1 s; vertical, 0.5 mm. Dotted lines are omitted parts on continuous recordings.

with muscle tissue (Fig. 3). The strand can be found in all larval instars and it persists in the adult without change.

Further evidence for a sensory function was obtained by recording from the distal part of the terminal nerve branch which supplies only the strand. Afferent volleys of spikes from the organ indicated the presence of several units responding in a phasico-tonic manner to trapezoid stretching of the strand (Fig. 4*a*). This identifies it as a stretch receptor. The attachments of the strand suggested a proprioceptive function characteristic of the strand receptor, and recording afferent spikes when moving the whole coxa shows a response to low and high angular velocities (Fig. 4*b*). This information may be used by the CNS for position control in still animals and for monitoring angular velocities of the moving coxa, as stretching the receptor strand causes increased motoneurone discharge of the coxal depressor muscles (Fig. 4*c*). Contractions of these muscles counteract forces that elongate the strand.

The metathoracic receptor does not seem to be the only one of this new morphological type in locusts. Peripheral cobalt stainings showed similar structures in a comparable position in the fore-and middle leg and others spanning the coxa–trochanter joints of all three leg pairs.

All previously described insect mechanoreceptors have their sensory cell bodies in the periphery as most invertebrate sense organs do. Exceptions have been found in some annelid[6] and crustacean[7–9] species, for which sensory neurones with somata in the CNS have been reported. The discovery of this new type of proprioceptor in the locust brings the insects in line with these other invertebrate groups. The location of the sensory structure in the proximal leg joints and their appearance at the light-microscopic level reminds one of certain strand receptors reported for decapod Crustacea[7]. However, there is a striking difference in signal propagation: locust organs send their information to the CNS by means of action potentials, whereas crustacean receptors only transmit graded potentials[8,9].

The ontogeny of the described sensory cells remains an unsolved problem: do they develop like insect mechanoreceptor cells from late ectodermal cells during embryogenesis with cell bodies migrating into the CNS or are they derived from neuroblasts like motoneurones and interneurones?

Dopamine depolarisation of mammalian primary afferent neurones

Joel P. Gallagher, Hiroe Inokuchi* & Patricia Shinnick-Gallagher

Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, Texas 77550

Dopamine (DA) is an important neurotransmitter or neuromodulator in the mammalian nervous system. As such, it is implicated in the aetiology and therapy of various disease conditions—for example, Parkinson's disease, schizophrenia, Huntington's disease and tardive dyskinesia. However, only limited electrophysiological information is presently available concerning dopamine receptors in the mammalian nervous system[1], and there are only three reports[2–4] in which intracellular techniques have successfully recorded the action of DA on individual central neurones. In all cases, DA depolarised the respective neurones. In the periphery, DA is reported to hyperpolarise superior cervical ganglia[5–9]. However, this hyperpolarisation has been shown to be due to activation of α-adrenoreceptors and not to a response of DA on a DA receptor[8,9]. Peripheral DA actions have also been described presynaptically[10,11], but are difficult to study electrophysiologically for technical reasons. As a result, little is known at the membrane level about the effects of drugs thought to modulate or interact with DA receptors. In the present report, we describe a depolarising action for DA on the cat dorsal root ganglion.

Lower lumbar dorsal root ganglia (DRG) were dissected from adult cats (2–5 kg) that were anaesthetised intraperitoneally (i.p.) with a mixture of α-chloralose (60 mg kg^{-1})) and pentobarbital (5 mg kg^{-1}). The isolated ganglia were maintained at 37 °C in physiological solution aerated with 95% O_2 and 5% CO_2. A physiological solution of the following composition was used to superfuse the preparation (in mM): NaCl, 117; KCl, 4.7; $CaCl_2$, 2.5; $MgCl_2$, 1.2; NaH_2PO_4, 1.2; $NaHCO_3$, 25 and glucose, 11.5. Standard intracellular recording techniques[12] using K-citrate (2 M) filled microelectrodes were used. Known concentrations of drugs were added to the superfusate.

We have been investigating the pharmacology of a γ-aminobutyric acid (GABA) receptor that has been characterised on the cell body of cat dorsal root ganglia[12]. As a result of *in vitro*[12–14] or *in vivo*[15] techniques with ganglia from adult animals, it has been assumed that receptors on the somata of primary afferent neurones may be similar to those on their terminals. There have been two reports[16,17] which suggest that neuroleptic drugs (agents thought to interact with central DA receptors) may also affect GABA–GABA receptor interactions.

---

* Present address: Department of Physiology, Kurume University Medical School, Kurume, Japan.

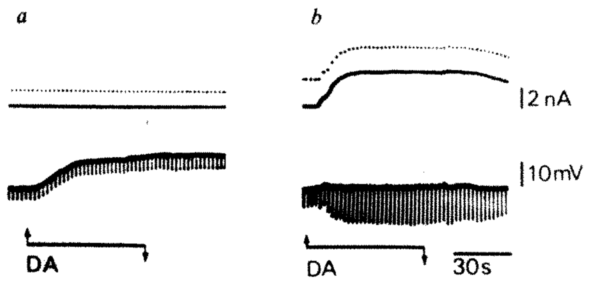

Fig. 1 Effects of bath applied DA (5×10^{-4} M) on membrane potential and resistance. *a*, Upper pair of tracings (current monitor) represents constant hyperpolarising current pulses. Lower tracing (voltage monitor), solid line represents membrane potential from which anelectrotonic responses deflect downward. *b*, Same as *a* except a current is applied manually during the DA application to prevent the drug-induced depolarisation. In these conditions, the membrane resistance increases during DA.

To examine this possibility, we applied the putative DA-antagonists chlorpromazine (CPZ) and haloperidol while monitoring iontophoretically induced GABA depolarisations. Neither CPZ nor haloperidol at concentrations to 10^{-5} M altered the GABA response. However, at 10^{-5} M, haloperidol occasionally depolarised the membrane and would block an action potential induced by cathodal stimulation through the recording electrode. A similar depolarising action for haloperidol had been reported at a DA receptor on a vertebrate neuronal cell hybrid[18]. As a result of this depolarising action by this DA antagonist, we undertook the following experiments to investigate whether DA has a direct action on these cells.

After impaling a neurone its effective membrane resistance (1/conductance) was determined from the ratio of voltage/current measurements. Electrotonic potentials required for the above measurements were generated by brief repetitive anodal current pulses delivered through the recording electrode. When DA was applied to the preparation, a sustained membrane depolarisation with little conductance change was recorded (Fig. 1*a*). Because DA depolarised the membrane at a slow rate, the membrane potential could be held constant during the DA application by passing a continuous hyperpolarising current through the recording electrode. In these 'manual clamp' conditions[19], DA decreased conductance (Fig. 1*b*). In one other report[3], the DA depolarisation was usually not associated with a conductance change. The lack of a conductance change during the unclamped dopamine response is probably due to the membrane rectifying properties of the dorsal root neurones. Because of the rectifying properties we intend to determine the ionic mechanism of this DA-induced depolarisation using voltage clamp techniques. Preliminary results show that unlike the GABA-induced depolarisation chloride is not involved in the DA-induced depolarisation, whereas a decreased potassium conductance is, at least, contributory.

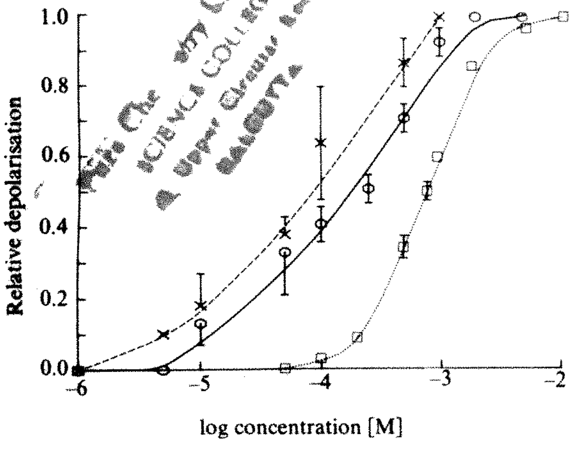

Fig. 2 log concentration–response relationships for DA ($K_a = 1.3\times10^{-4}$ M), apomorphine ($K_a = 7\times10^{-5}$ M) and GABA ($K_a = 7.8\times10^{-4}$ M). ×, Apomorphine; ○, dopamine; □, GABA.

Dopamine, at various concentrations, produced similar slow membrane depolarisations in 75% of the cells to which it was applied (209/275). In no instance did DA hyperpolarise the membrane. The complete concentration–response relationships for DA from 13 neurones are depicted in Fig. 2. For comparison, various concentrations of apomorphine ($n = 4$), a specific DA agonist, and GABA ($n = 10$) were also applied to the preparation. Apomorphine ($ED_{50} = 7\times10^{-5}$ M) was at least twice as effective as DA ($ED_{50} = 1.3\times10^{-4}$ M) in causing a membrane depolarisation. The maximum depolarisation produced by DA and apomorphine was about 10 mV. Both DA and apomorphine produced sustained, non-desensitising depolarisations for as long as the drug was in contact with the preparation. This action differed from one observed when GABA is applied for a prolonged period because the GABA depolarisation rapidly declines as the receptor becomes desensitised[12,13].

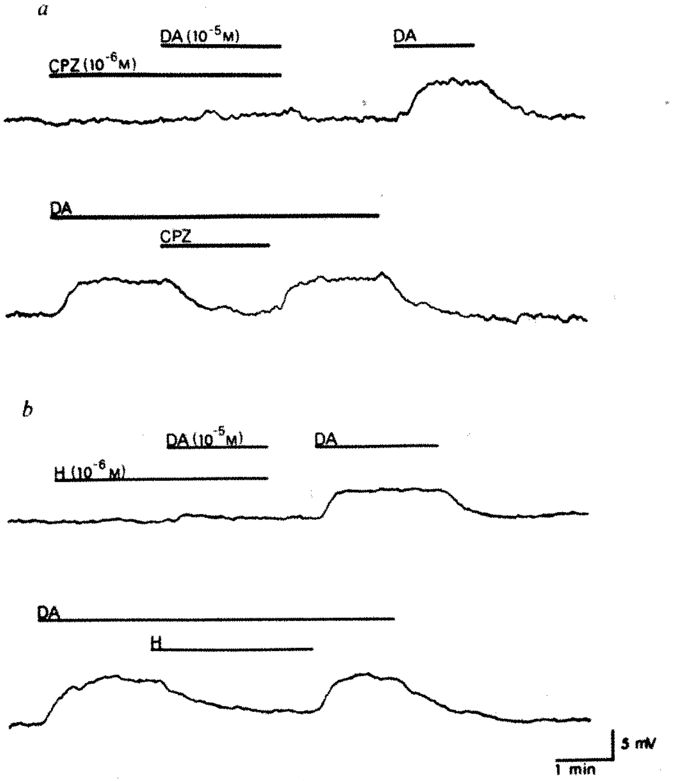

Fig. 3 Effects of antagonists on dopamine depolarisation. *a*, Chlorpromazine (CPZ) effects on membrane potential and on DA-induced depolarisation. *b*, Haloperidol (H) on membrane potential and on DA-induced depolarisation.

Of the drugs tested, only chlorpromazine (CPZ) and haloperidol antagonised the action of DA (Fig. 3). CPZ (10^{-6} M) had no effect on the resting membrane potential but antagonised the depolarising action of DA (Fig. 3*a*). In the continued presence of DA, the addition of CPZ inhibited a DA depolarisation. Haloperidol (10^{-6} M) produced a similar antagonistic action (Fig. 3*b*).

Other amines were applied to the sensory ganglion by the superfusion technique. Although noradrenaline depolarised the ganglion, it did not depolarise to the same degree as DA, even at concentrations 10 times greater than that of DA. The depolarisation induced by noradrenaline could not be antagonised by phentolamine, an α-adrenoreceptor antagonist. Propanolol, a β-adrenoreceptor antagonist was also ineffective in blocking the action of the amines. Furthermore, adrenaline and serotonin were less effective depolarising agents than noradrenaline. This weak effect of serotonin was unexpected as it has been shown to be active at the nodose ganglion[20] and the superior cervical ganglion[21]. Isoprenaline did not depolarise.

The concentrations of DA ($ED_{50} = 1.3 \times 10^{-4}$ M) required to depolarise the ganglion are high. Nonetheless, we believe that this action is specific because the responses are antagonised by classical DA antagonists and not affected by the α- or β-adrenoreceptor antagonists. In a recent study with isolated toad spinal cords, catecholamines, including DA, at concentrations similar to those used here, depolarised dorsal root terminals[22]. In addition, there is evidence that dopaminergic neurones are present in the mammalian spinal cord[23]. These authors have described a differential distribution for DA within the cord; DA concentration was found to be two to three times higher in the dorsal horn than in the ventral horn. This distribution pattern would support the fact that DA receptors on the sensory ganglion soma may also be present on their terminals. At present, there is no published evidence regarding DA binding to dorsal root ganglia.

The dorsal root ganglion may provide us with essential information about the interaction of DA with its receptor and of drugs thought to alter its action at the membrane level. With this knowledge a better insight into the therapeutic approach to various diseases of the central nervous system may be achieved.

We thank Drs Betty J. Williams and Odd S. Steinsland for critical review of the manuscript. This research was supported by USPHS grant NS 13727 from the National Institute of Neurological and Communicative Disorders and Stroke.

Serotonergic neurones are not involved in action of L-dopa in Parkinson's disease

Eldad Melamed, Franz Hefti, James Liebman, Arthur J. Schlosberg & Richard J. Wurtman

Laboratory of Neuroendocrine Regulation, Department of Nutrition and Food Science, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

Under normal circumstances, L-dopa is converted to dopamine (DA) in DA-containing neurones of the corpus striatum by the enzyme aromatic L-amino acid decarboxylase[1]. Although L-dopa has been used widely to treat Parkinson's disease, the site of its decarboxylation to DA in the parkinsonian striatum is unknown. It was initially assumed that dopa administration enhances DA synthesis and release in surviving nigrostriatal neurones[2–6]. Subsequent *in vitro* studies provided evidence that exogenous dopa might also be taken up, decarboxylated[7–9], and released as DA[8,10] by serotonergic terminals, suggesting that non-dopaminergic neurones also may mediate some of dopa's therapeutic effects[10]. During long-term dopa treatment in parkinsonism, its efficacy often declines[11], and diurnal fluctuations in its effectiveness (the 'on-off' phenomenon) can become manifest in previously responsive patients[12]. If the effects of dopa depend solely on surviving dopaminergic neurones, its decreasing efficacy with time could imply continuing degeneration of striatal terminals[11,13]. However, if exogenous dopa can also affect striatal DA transmission by being decarboxylated in serotonergic neurones, the declining therapeutic efficacy could reflect involvement of serotonergic neurones in the pathology of Parkinson's disease; this has previously been reported, but remains controversial[14–17]. Therefore, we examined the decarboxylation of exogenous dopa in an animal model of parkinsonism—rats with unilateral nigrostriatal lesions[18]—which were further subjected to lesions of the striatal serotonergic projections. Our data indicate that combined destruction of striatal dopaminergic and serotonergic terminals has little additional effect, beyond destroying dopaminergic neurones, on dopa's ability to enhance striatal DA release and do not favour the concept that serotonergic neurones are involved in mediating the therapeutic effects of L-dopa.

Groups of 5–10 Sprague–Dawley rats (200–250 g; Charles River) had free access to water and Big Red rat chow (Charles River). Lesions in midbrain dorsal and median raphe nuclei were produced electrolytically (2 mA, 20 s in the dorsal and 2 mA, 25 s in the median raphe nucleus). One month later, unilateral nigrostriatal lesions were performed in raphe-lesioned and control rats by injecting stereotaxically 8 μg 6-hydroxydopamine (OHDA) in 4 μl saline containing 0.2 mg ml^{-1} ascorbic acid into the right anteromedial substantia nigra (level A 2400, according to König and Klippel[19]). This was immediately followed by an additional injection of 4 μg in 2 μl into the right medial forebrain bundle (level A 4000) to increase the lesion's severity. Two weeks after the OHDA treatments, animals were injected with L-dopa (100 mg per kg, intraperitoneally), placed in metal cylinders (35 cm diameter), and their turnings (full circles) were counted during the 5-min interval between 40 and 45 min after the injection. Rats were then decapitated and both striata were dissected separately and frozen on dry ice. Tissues were homogenised in ice-cold distilled water; buffered aliquots were assayed for tyrosine hydroxylase (TH)[20] and dopa decarboxylase (DDC) activities[21], and deproteinised aliquots for 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA), using high-performance liquid chromatography with electrochemical detection[22]. Serotonin in small striatal samples was determined by an enzymatic–isotopic method[23].

Since striatal DA concentrations after dopa administration can no longer indicate the extents of nigrostriatal lesions, we used TH activity for this purpose. TH activities and DA levels were highly correlated ($r = 0.91$) in OHDA-lesioned striata of rats not receiving dopa (F.H. *et al.*, in preparation). After OHDA injections, there were marked reductions (by 90–95% compared to control or contralateral striata) in TH activity in lesioned striata, indicating severe unilateral destruction of the nigrostriatal system in all groups of animals (Table 1). The raphe lesions produced marked reductions (by approximately 90%) in serotonin levels in both OHDA-lesioned and contralateral striata (0.75 ± 0.15 and 0.55 ± 0.13 ng per mg protein, respectively; mean ± s.e.m.), compared with levels in control striata (6.68 ± 1.18 ng per mg protein). Although dopa administration has been reported to decrease brain serotonin levels[24], we found no decrease in another group of unlesioned, dopa-treated animals (6.82 ± 0.52 ng per mg protein, $n = 10$). DDC activity was reduced in OHDA-lesioned striata by 76–87% compared with

0028-0836/80/080772—03$01.00

those in control and contralateral unlesioned striatal tissues. Despite severe destruction of the nigrostriatal system, DDC activity was relatively less reduced than TH activity, confirming that striatal DDC exists both within and outside dopaminergic neurones[25]. DDC activity in striata of animals with unilateral nigrostriatal lesions was not decreased further if animals were subjected to raphe lesions. Dopa administration caused no significant changes in TH and DDC activities in lesioned or control striata.

Nigrostriatal lesions produced marked ipsilateral depletions of striatal DOPAC and HVA (Table 1). Dopa administration increased the concentrations of these DA metabolites in unlesioned, contralateral striata. It also markedly elevated DOPAC and HVA levels in lesioned striata, indicating that decarboxylation of exogenous dopa occurs despite a marked reduction in the number of DA-containing nerve endings. In rats with combined raphe-nigral lesions, the increases in striatal DOPAC and HVA after dopa administration were similar to those observed in animals with unilateral nigrostriatal lesions alone. This indicates that dopa decarboxylation in striata containing a diminished number of dopaminergic terminals is not altered after additional destruction of the striatal serotonin input.

Dopa reportedly increases locomotor activity in rats, and this action is further amplified after destruction of central catecholaminergic neurones by intraventricular OHDA[26]. If brain serotonergic neurones were also destroyed, dopa's effects on motor activity were either reduced[27] or unchanged[28]. In rats with unilateral nigrostriatal lesions, dopa administration induces contraversive circling behaviour, attributed to enhanced DA synthesis and release within the lesioned striatum[18]. In the present study, dopa-treated rats with combined raphe-nigral lesions displayed vigorous turning away from the lesioned side; this behaviour did not differ from circling noted in rats with unilateral nigrostriatal lesions alone (Table 1). This finding contradicts a recent report[29] showing diminished rotational response to L-dopa when both striatal serotonergic and dopaminergic neurones have been destroyed unilaterally. In this report, the unilateral lesioning of serotonergic neurones (by injecting 5,7-dihydroxytryptamine into one lateral ventricle), probably caused an additional asymmetry between the two striata, which by itself could have affected turning behaviour[30,31]. In our study, raphe lesions reduced serotonin levels by about the same extent in both striata; such lesions do not affect the circling associated with asymmetries in the nigrostriatal system[32,33].

To examine the relative contribution of DDC within serotonergic neurones to total striatal DDC activity, rats were subjected to electrolytic lesions in dorsal or median raphe nuclei, or in both nuclei. Dorsal and combined dorsal-median raphe lesions reduced striatal serotonin content (Fig. 1), confirming the presence of a projection from the dorsal raphe to the striatum in the rat[34,35]. Striatal DDC activity (measured using [1-^{14}C]dopa as substrate) did not decrease despite marked reductions in serotonin. This finding is consistent with our previous observation (Table 1) that a raphe lesion does not further reduce striatal DDC activity in rats with nigrostriatal lesions. These data suggest that the decarboxylase contained within serotonergic neurones contributes insignificantly to the total DDC activity of the striatum.

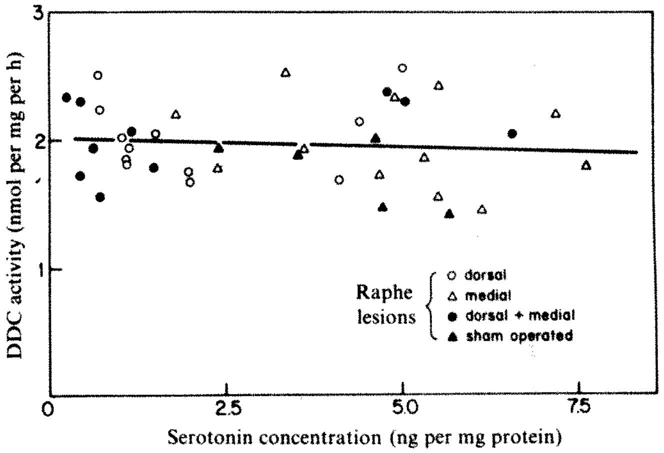

Fig. 1 Striatal dopa decarboxylase activity and serotonin concentrations in rats with electrolytic lesions in the midbrain dorsal or median raphe nuclei, or in both nuclei. Sham-operated rats were used as controls. Rats were killed 2 weeks after the lesions were produced, and the right and left striata from each rat were pooled and analysed for dopa decarboxylase activity (using [1-^{14}C]dopa as substrate)[21] and for serotonin[23]. Regression line was calculated by the least squares method; $r = -0.10$.

Our study shows that in rats with severely damaged nigrostriatal systems, an additional lesion destroying striatal serotonergic neurones does not alter the ability of exogenous dopa to enhance DA release or to cause a behaviour (contraversive circling) thought to be induced by DA release. Hence, in our experimental conditions, dopa's effects possibly are not significantly dependent on its uptake in, decarboxylation in, or

Table 1 Effect of dopa on striatal DOPAC and HVA concentrations in rats with combined raphe and unilateral nigrostriatal lesions

	TH	DDC	DOPAC	HVA	Turning

Values are means ± s.e.m. Rats were lesioned electrolytically in the dorsal and median raphe nuclei. One month later, these animals and other control rats were injected unilaterally with 8 μg OHDA into the substantia nigra and 4 μg into the medial forebrain bundle. Two weeks after the OHDA lesions were produced, animals received 100 mg per kg L-dopa intraperitoneally and were put in metal cylinders for measurement of turning behaviour between 40 and 45 min after injection. Rats were then decapitated and the enzyme activities (TH and DDC) and DOPAC and HVA concentrations were measured in both striata. Data were subjected to analysis of variance followed by Scheffe's test.

release as DA from striatal serotonergic terminals[8-10]. Thus our findings do not suggest a major role for serotonergic neurones in mediating dopa's effects in Parkinson's disease. In intact striata, DDC activity is localised predominantly in DA-containing terminals (Table 1). The DDC activity remaining after nigrostriatal lesions could be contained within surviving DA-containing neurones and in other striatal constituents, such as the capillaries[36,37]. DA formed from dopa by DDC within capillary endothelium probably lacks functional significance, since it may not be able to traverse the blood–brain barrier and reach striatal synapses[36,38,39]. The rotational behaviour[40] and striatal DA formation (E.M. *et al.*, in preparation) after dopa administration are not abolished when rats with unilateral nigrostriatal lesions are given a drug that blocks vascular DDC, indicating that, in lesioned rats, dopa is also converted to DA outside striatal capillaries. Further studies should determine if this decarboxylation occurs exclusively within surviving dopaminergic neurones or also in other striatal compartments.

This study was supported in part by the NIH and the American Parkinson's Disease Association. E.M. was supported by an NIH-Fogarty International Fellowship and F.H. by the Swiss National Science Foundation.

Black widow spider toxin-induced calcium fluxes and transmitter release in a neurosecretory cell line

A. Grasso, S. Alemà, S. Rufini & M. I. Senni

Laboratory of Cell Biology, CNR, Via Romagnosi 18/A,
00196 Rome, Italy

Several polypeptide neurotoxins affect presynaptic functions by interfering with chemical neurotransmission. This group of toxins includes botulinum toxin[1], tetanus toxin[2], β-bungarotoxin[3] and black widow spider toxin (BWSTx)[4-6]. While the effect of the first three toxins is mainly a rapid and severe block of neurotransmitter release, BWSTx affects transmission by a massive stimulation of mediator release[4-6]. Despite various hypotheses put forward to explain the action of BWSTx at the level of nerve terminals, there is still a considerable degree of uncertainty as to the cation dependence of venom action[7-11]. Study of the toxin mode of action at the biochemical level has been hampered by the complexity and cellular heterogeneity of the preparations used, neuromuscular junction[10] or synaptosomes[6]. PC12 cell line, derived from a rat phaeochromocytoma[12], seems to be an excellent model in view of its property of synthesising and storing noradrenaline, dopamine and acetylcholine, and releasing them in depolarising conditions[13]. We have recently shown that highly purified BWSTx stimulates secretion from PC12 cells of previously taken up radioactive dopamine (DA) and noradrenaline (NA) (ref. 14 and manuscript in preparation). We report here that the earliest detectable event after toxin treatment of such cells is a massive increase of cytosolic calcium.

When PC12 cells grown in monolayer and loaded with ^{3}H-labelled DA are exposed to BWSTx in a nominally Ca^{2+}-free medium, containing 1 mM EGTA, the radioactivity released in the medium equals that of untreated controls (less than 1% of total intracellular radioactivity per min). Extensive washing of the cells and substitution of the latter medium with a Ca^{2+}-containing medium (1.8 mM) results in a release of more than 30% of total labelled catecholamines in the following 5 min (Fig. 1). The amount of transmitter release is quantitatively comparable with that obtained with an equal amount of toxin added to a Ca^{2+}-containing medium (dashed line, Fig. 1). BWSTx-induced release of ^{3}H-DA is completely blocked if cells are pre-exposed to micromolar concentrations of concanavalin A or if toxin is challenged with monospecific antibodies before addition to cultures. However, if lectin or antibodies are added after toxin is bound to cell membrane in EGTA, Ca^{2+}-triggered effect (see Fig. 1) is maintained (data not shown). Furthermore Ca^{2+}-dependent release of DA after toxin treatment is temperature-dependent, being reduced by over 80% when temperature is lowered from 37° to 8 °C.

Table 1 Effect of several agents on Ca^{2+} flux and dopamine release induced by BWSTx and K^+

	Percentage inhibition of maximum effect			
	^{45}Ca flux		DA release	
Condition	BWSTx	K^+	BWSTx	K^+
TTX (1×10^{-6} M)	0	0	0	0
Sea anemone Tx II (5×10^{-6} M)	0	0	0	0
Co^{2+} (1×10^{-3} M)	0	80	0	75
(2×10^{-3} M)	35	98	30	95
Cd^{2+} (2×10^{-3} M)	ND	ND	0	90
Verapamil (5×10^{-5} M)	32	70	10	75
Concanavalin A (5×10^{-7} M)	100	0	100	0

Experimental conditions were as described in Fig. 2, except that BWSTx (8 nM) and K^+ (56 mM) were directly added to cultures in standard HR medium (1.8 mM $CaCl_2$). ^{45}Ca uptake and ^{3}H-DA release were measured after 6 min incubation at 25 °C. Each value represents the mean of duplicate assays in a typical experiment. Values are expressed as a per cent of maximum effect in control treated cultures. ND, not determined.

0028-0836/80/080774—03$01.00

It thus seems that BWSTx binds to PC12 membrane in the absence of Ca^{2+} but is unable to induce catecolamine secretion unless physiological concentrations of divalent cations are added to the medium. The next question which arises concerns the site at which external calcium ions are necessary to make the toxin effect apparent. Is the toxin directly activated by Ca^{2+} ions or does it induce transmitter release by allowing Ca^{2+} ions to enter the cells? To test the latter question we made use of PC12 cells exposed to toxin in a medium containing EGTA. After 10 min unbound toxin was extensively washed out and the cells quickly exposed to a medium containing 1.8 mM ^{45}Ca. As shown in Fig. 2*a*, immediately after the addition of the Ca^{2+}-Ringer a massive influx of ^{45}Ca is measurable in cells pretreated with a saturating concentration of toxin (7 nM). This influx is several times higher than that induced by depolarising concentrations of K^+ or by 0.7 nM toxin. In the latter case net stimulation of ^{45}Ca uptake tends to level off after about 100–150 s. Release of ^3H-DA was followed in conditions identical to those used for the Ca^{2+} flux experiments (Fig. 2*b*). Stimulation of DA release over background is very rapid and its time course seems to be concomitant with that of ^{45}Ca influx at both toxin concentrations. Interestingly, although the uptake of ^{45}Ca elicited by 7 nM toxin is 10- to 12-fold higher than that due to 0.7 nM toxin (or 56 mM K^+), the ratio, as far as DA secretion is concerned, is only 2.5–3.0. This suggests that only a proportion of the Ca^{2+} entering cells is saturating those intracellular sites involved in secretion, the rest being perhaps responsible for the cellular swelling observed as a consequence of long-term exposure to high toxin concentrations (unpublished results). Note that while these results suggest initial Ca^{2+} entrance as a primary event in the induced release, a secondary mobilisation of internal stores of Ca^{2+} is not to be excluded.

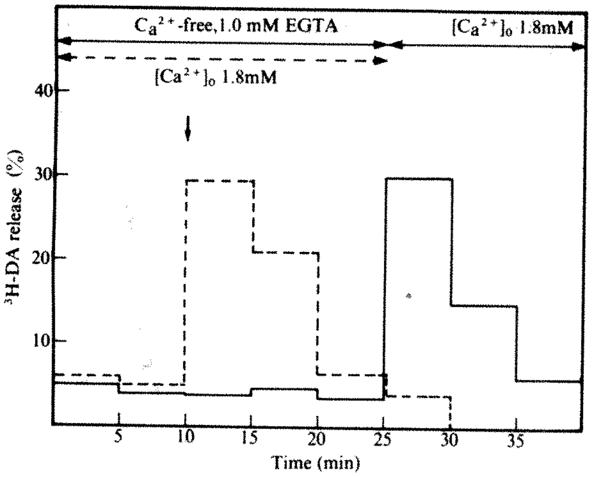

Fig. 1 Influence of Ca^{2+} on dopamine release in response to BWSTx. PC12 cells were grown as monolayer on collagen-coated Petri dishes (35 mm) at a density of 10^6 cells per dish. Cells were washed free of culture medium and incubated at 37 °C for 60 min in 1 ml of HEPES–Ringer (ref. 13) (HR) supplemented with 1 μCi per dish ^3H-DA, 10^{-4} M pargyline and 0.5 mg BSA ml^{-1}. Specific activity of ^3H-DA (Amersham) was 6–7 Ci $mmol^{-1}$. At the end of the uptake period, cultures were brought to 25 °C, washed three times with HR (containing 1.8 mM $CaCl_2$). Sister cultures were washed with a modified Ca^{2+}-free HR buffer (also containing 1 mM EGTA). Cultures were then incubated for 5-min periods with 1-ml aliquots of the respective buffers. The releasing medium was collected from the dishes by careful suction directly into scintillation vials. After two 5-min intervals, experiment was started (arrow) by addition of 5 pmol of purified BWSTx (molecular weight 125,000)[6]. Toxin was present only in the following 5-min interval. Dashed line refers to cultures in the presence of HR. Continuous line refers to cultures in EGTA-HR. In this set, Ca^{2+}-containing HR was replaced after three EGTA-HR washes following toxin addition. At the end of the experiment cells were solubilised with 2% SDS. Radioactivity was counted in 5 volumes of Aquasol-2. ^3H-DA release is expressed as a per cent of total radioactivity present in the cells at the beginning of the experiment. The cells remain firmly attached to the substrate during the whole experiment.

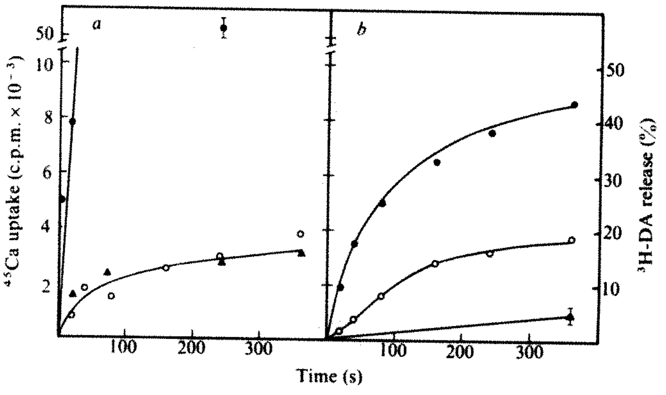

Fig. 2 Time course of ^{45}Ca uptake and ^3H-DA release induced by two different toxin concentrations. *a*, PC12 cells were grown in conditions identical to those described in Fig. 1. Cultures, after washing with EGTA-HR, were incubated for 10 min at 25 °C with the same buffer but containing, when appropriate, 0.7 (○) and 7.0 (●) nM BWSTx and bovine serum albumin 0.5 mg ml^{-1}. The medium containing toxin was then removed and cultures challenged with 1 ml of HR containing 1.8 mM ^{45}Ca (5×10^6 c.p.m. ml^{-1}) for the indicated time intervals. 56 mM KCl was present in K^+-stimulation experiments (▲). Uptake was terminated by washing the dishes quickly three times with HR and then solubilising the cells in 2% SDS. Background Ca^{2+} uptake (0.05–0.1 nmol per min per 10^6 cells) was substracted from total counts to obtain the values plotted above. Possible exchange of Ca^{2+} during the course of our measurements was ignored. *b*, PC12 cells preloaded at 37 °C with ^3H-DA as described in Fig. 1, were equilibrated at 25 °C in EGTA-HR also containing the same toxin concentrations as in (*a*) for 10 min. After removal of toxin release was started by addition of standard HR. Background release of tritiated DA (less than 1% per min) is given (▲). DA release expressed as in Fig. 1. Each point represents the mean from three different experiments. Net Ca^{2+} fluxes of comparable magnitude were observed also if BWSTx was added in a standard HR medium. However kinetics were somewhat modified because of toxin diffusion and binding to cells. BWSTx did not cause uptake of ^{45}Ca by non-secretory cells such as normal or transformed chick fibroblasts and rat myoblasts.

Two possible mechanisms by which BWSTx might enable Ca^{2+} to enter the cells are: (1) activation of physiologically operating voltage-dependent Ca^{2+} channels, which have been recently described by Stallcup in PC12 cells[15]; or (2) induction of new channels somewhat analogous to those formed by toxin on artificial lipid bilayers[16]. We found that in agreement with previous findings, both transition metals and verapamil (a calcium-channel blocker) fully inhibit K^+-induced Ca^{2+} influx as well as DA release[17,18] (Table 1). Such full inhibition was not observed when the same compounds were tested on toxin, thus suggesting that the major part of BWSTx effect does not involve direct activation of voltage-dependent Ca^{2+} channels. The moderate reduction in Ca^{2+} entry (and hence in DA release) observed at high Co^{2+} concentrations might be due to Co^{2+} permeating in place of ^{45}Ca, but being unable to stimulate release (see ref. 18). An alternative explanation might involve BWSTx acting through two distinct mechanisms—induction of 'specific' channels and a secondary contribution from Co^{2+} and verapamil-sensitive channels, perhaps activated by a concomitant depolarisation. However, support for the idea that Ca^{2+} entry elicited by toxin is unlikely to involve voltage-dependent channels comes from the observation that, at variance with potassium[18], transmitter release induced by the toxin is not inhibited by high Ca^{2+} concentrations (10 mM) (data not shown). Finally, ^{45}Ca flux induced by BWSTx does not require the presence of Na^+, being enhanced by a factor of two, possibly through a mechanism discussed earlier[15], in a Na^+-free-sucrose medium; even dopamine release is not appreciably affected in the same experimental conditions.

The main result of our experiments is the demonstration that BWSTx produces a rapid and massive influx of Ca^{2+} ions in a toxin-responsive, neurosecretory cell. The main consequence of Ca^{2+} influx is the release of neurotransmitters presumably through a typical exocytotic process[19,20]. Although we have no direct evidence that other cations besides Ca^{2+} cross the cell membrane as a consequence of toxin action, in our conditions neither Na^+ nor Mg^{2+} alone seem to effectively substitute for Ca^{2+} in inducing transmitter release. The present work also confirms and extends the previous observations[21,22] on the antagonistic effect of concanavalin A (see Table 1) by showing that the lectin inhibits BWSTx-induced Ca^{2+} uptake. On the basis of the available evidence, it seems reasonable to postulate that binding to a concanavalin A-sensitive 'receptor' is an obligatory step for the formation of the previously discussed Ca^{2+} 'channels'.

We thank Dr A. Levi for comments and suggestions and Dr L. Greene for providing the PC12 cell line. This work was in part supported by a CNR grant under the Controllo Crescita Neoplastica programme. This paper is dedicated to Mr B. Capparella (deceased February 1979), who by his unique skill in spider collection, has helped past and present research on Latrodectism.

X-ray-induced *in vitro* neoplastic transformation of human diploid cells

Carmia Borek

Departments of Pathology and Radiological Research Laboratory, Department of Radiology, Cancer Center/Institute of Cancer Research, Columbia University College of Physicians and Surgeons, New York, New York 10032

Techniques have recently been developed to identify and score quantitatively neoplastic transformation caused by X rays in cultured cells derived from rodents[1]. Because of their relevance to estimates of human cancer risk, it is clearly desirable to carry out similar experiments with cultured cells of human origin. The present report describes for the first time the neoplastic transformation *in vitro* of human diploid cells by X-ray irradiation into cells which can progress *in vitro* into advanced stages of neoplastic development, namely, to form colonies in agar and give rise to tumours when injected into nude mice.

We used an early passage of skin fibroblast strain KD cells, originally derived from a skin biopsy of an adult woman[2,3]. The cultures were in their fifth cell passage, dating from the original biopsy. Chromosome G banding analysis carried out on the cells on arrival indicated a normal diploid human karyotype. The doubling time of the KD cells as determined by growth curve analysis[4] was 30–32 h.

The cells were routinely maintained in Eagle's minimum essential medium (MEM) containing 10% fetal bovine serum and 1% human serum (GIBCO) and incubated at 37 °C. A dose–response curve for cell survival was carried out as described elsewhere[5] (see Fig. 1). The scheme for transformation experiments is described in detail in Fig. 2 legend. All cells were fed twice a week. Four separate experiments have been carried out using antipain[6] or β-oestradiol. In each experiment control cultures included unirradiated, untreated cells as well as cells unirradiated, but treated with antipain or β-oestradiol. These were set up in equal numbers to the experimental flasks and subcultured in the same manner.

Within 2 months of irradiation, discrete foci were detected in the pretreated, irradiated cultures which had been left untouched following the 1:12 split and were now at high density. The foci, consisting of cells with a subtle irregularity in cell to cell orientation, were visible under phase microscopy. Two or three foci were initially detected in each experiment in both antipain- and oestradiol-pretreated, irradiated cultures, suggesting that these compounds were equally effective in potentiating radiation-induced transformation. Within 3 months, 30–40 of these foci per experiment were observed in most of the high-density flasks but not in those which had been given a further subculture (Fig. 2). The latter exhibited these foci after transferring the cells at high density (2×10^6) to 100-mm Petri dishes.

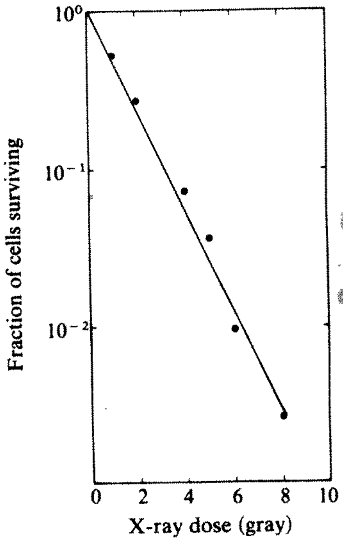

Fig. 1 Cell survival of KD cells following irradiation by X rays, from a Sieman's 300 kVp constant potential generator with an added filter of 0.2 mm copper.

The foci increased in size. A multilayering of cells made them clearly visible to the naked eye (Fig. 3). No foci appeared in the unirradiated cells or in cells treated with antipain or oestradiol alone.

By exchanging the medium for medium containing low calcium concentrations[7], the cells in the morphologically transformed foci underwent an additional, more dramatic morphological alteration (Fig. 3), whereas the normal cells degenerated within 24 h.

Chromosomal G banding analysis carried out on cells isolated from the primary foci showed a human chromosomal constitution with a diploid to near-diploid number of chromosomes

0028-0836/80/080776—03$01.00

(range 46–49). A more detailed karyotype will be published elswhere. Saturation density determined on the transformed cells cultured from the foci showed a twofold increase in saturation density over that of the normal. The transformed cells but not the normal parental cells were agglutinable by 25 μg ml^{-1} of concanavalin A (Miles-Yeda).

The ability to proliferate at low serum concentrations (1%) was not confined to the transformed human cells[8] as in rodent systems[1,4], but was also a property of the normal KD cells grown in the same conditions (10^5 cells per 60-mm Petri dish).

Cells isolated from the multilayered foci were seeded in semi-solid agar[9], where they proliferated to form distinct spherical colonies (Fig. 3) with a cloning efficiency of 2–3%. None of the unirradiated KD cells or the irradiated but untransformed cells (seven samples of each) was able to proliferate in agar. Colonies isolated from agar could be recultured in liquid medium or further propagated in agar.

Fig. 2 Experimental design for the induction of human cell transformation *in vitro* by 4 gray of X rays (1 gray = 100 rad). Cells were trypsinised (0.25% trypsin), suspended in complete medium and plated in tissue culture flasks (75 cm^2) (Falcon) at 2.6×10^5 cells. Two days later, the medium was replaced with MEM containing 0.1% serum for 24 h, whereby cell proliferation was greatly reduced. After 24 h, medium was again exchanged, this time for complete medium (11% serum) containing either 6 μg ml^{-1} of the protease inhibitor antipain[6] or 1 μg ml^{-1} β-oestradiol (Sigma). Experimental cultures were irradiated 12 h later with 4 gray of X rays as previously described[5]. All cultures were divided into two 10–12 h after irradiation and reseeded in fresh complete MEM without antipain or oestradiol. At near confluency, one of the two flasks was subcultured into 12 flasks, the other being left undisturbed. In each experiment, when these 12 flasks reached confluency, one flask was subcultured 1 : 10 and thus defined as 'continuously passaged', and the remaining 11 flasks were left at high density.

The ultimate proof of the neoplastic nature of the cells transformed *in vitro* is their ability to form tumours in an appropriate host. Swiss *nu/nu* mice were injected intradermally with 5×10^6 cells (suspended in 1 ml medium) into the subscapular region of animals X-ray-irradiated 24 h earlier with 450 rad or unirradiated[10].

Whereas the five transformed lines tested formed colonies in agar, three gave rise within 6 weeks both in the irradiated and unirradiated mice to tumours which have been characterised as noninvasive fibrosarcomas. Cells cultured from the tumours possessed a human karyotype which will be described in detail elsewhere. None of the unirradiated or the irradiated but untransformed cells (seven samples of each) gave rise to tumours in the nude mice.

The present experiments show that human diploid cells can be transformed *in vitro* into tumorogenic cells by X-ray-irradiation. Cultures which were treated and irradiated in the non-dividing state, as well as those which were allowed only four or five cell divisions before reaching confluency (and not subcultured further), did not exhibit transformed foci. This indicates that cell replication is required for the fixation and expression of radiation-induced neoplastic transformation in diploid human cells, and a quantitative assessment is now in progress. This requirement has been shown to exist in the case of rodent cells transformed *in vitro* by radiation[11-13] or chemicals[14,15] and in human cells transformed *in vitro* by chemicals[3]. It was of interest that cells which were not recognisable as transformed at low density expressed transformation when replated at high density in close contact.

Phase ×58. *c*, The same area as in *b* 24 h after incubation in low calcium. Phase ×58. *d*, X-ray-transformed KD cells growing in 0.33% agar. ×12.

The complex experimental design used here takes advantage of the following. (1) The cells which were well adapted to complete medium were subjected to conditions of serum deprivation for a period of 24 h, thus reaching a complete quiescence, indicated in these conditions by specific conformational changes in chromatin (Hoen, personal communication). (2) The addition of complete medium 24 h later led to a synchronous wave of DNA synthesis and treatment of the cells at that point enabled the capturing of cells entering S phase.

We do not know the mechanism of action of oestradiol and antipain in this system. Neither compound exhibited mitogenic activity at the concentration used and both seemed equally effective. We have previously shown that antipain, a protease inhibitor, when present in cultures during irradiation enhanced the yield of X-ray-induced neoplastic transformation in hamster and mouse cells[16]. Oestradiol has been used to potentiate chemically induced transformation[17] and although steroids have many functions, they do have some protease inhibitor activity[18]. Thus, one could speculate that the enhancing action of both compounds may be in part through a common mechanism related to this property.

Although the above experimental regime has been successful for the induction and detection of radiation-induced transformation in the KD cells, it must be stressed that we are relatively ignorant of the best experimental design for inducing transformation and detecting transformants in human cells. Note, for example, that although partial cell synchrony and potentiation of transformation by hormones was a necessary step in the transformation of some diploid human cells by chemical carcinogens[17], it was not required for the induction of transformation in other diploid cells[3]. Because the latter[3] were, in fact, the KD cells, we are now evaluating other experimental designs to induce and detect transformation by radiation in the human cells. The ability to transform human cells *in vitro* by

X-ray irradiation opens up a wide range of studies which should aid in the assessment of human risk to radiation-induced carcinogenesis and in the evaluation of treatments to inhibit its expression and progression.

I thank Mr A. Ong and Mr H. Mason for technical assistance, Dr C. Geard for help with chromosome analysis, Dr E. Borenfreund for help with the nude mice, Dr W. Troll and the U.S.-Japan cooperative program for the antipain, Dr J. F. Whitfield for the low calcium medium, and Dr T. Kakunaga for the KD cells. This investigation was supported by grant CA 12536 to the Radiological Research Laboratory/Department of Radiology, and grant CA 13696 to the Cancer Center/Institute of Cancer Research awarded by the NCI, DHEW, and by contract EP-78-S-02-4733 from the Department of Energy.

Mechanical significance of streptostyly in lizards

Kathleen K. Smith

Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138

The morphology of the lizard skull has been a subject of study for more than a century, particularly with respect to the morphology and function of the major jaw adducting muscles[1–5] and the mechanics of the moving parts[6–9]. It is possible that controversies surrounding the extent and timing of bone movement, muscle contraction and force generation will be resolved by techniques such as electromyography, cineradiography and measurement of bone strain[3,10]. I present here data that facilitate a reconsideration of the function of the pterygoideus muscle, one of the two major jaw adducting muscles, and the mechanical significance of movements of the quadrate around the quadrate-squamosal joint. This movement, known as streptostyly[6] occurs in all living lizards[11] and also characterises the earliest members of the order[12–14]. On the basis of my data I propose that streptostyly in lizards is a means by which the mechanical advantage of the pterygoideus muscle is increased, so that this muscle makes a major contribution to bite force.

The data were gathered from simultaneous electromyographic and cineradiographic experiments on *Varanus exanthematicus, Ctenosaura similis*, and *Tupinambis nigrapunctata*, cineradiographic experiments on *Uromastix aegyptius*, and strain gauge and force transducer recording of biting in *V. exanthematicus*. Materials and methods were essentially the same as before for both cineradiography and electromyography[10] and for strain gauge experiments[11]. (Full details of the experiments will be reported elsewhere.)

Figure 1 shows the major morphological features to be discussed here. Of the three major jaw adducting muscles in lizards, the pterygoideus in particular has several interesting features. It is large; in *Varanus*, for example, it is 30–40% of the total adductor mass by weight; however, its mechanical advantage around the quadrate-mandibular joint is small. Generally it is not emphasised as an effective force producing muscle[3,7–9] or it is assumed to be important only in initiating fast closing[4,5]. Its position is such that in addition to any effect at the quadrate-mandibular joint, contraction will draw the lower end of the quadrate forward (protraction) relative to the quadrate-squamosal joint.

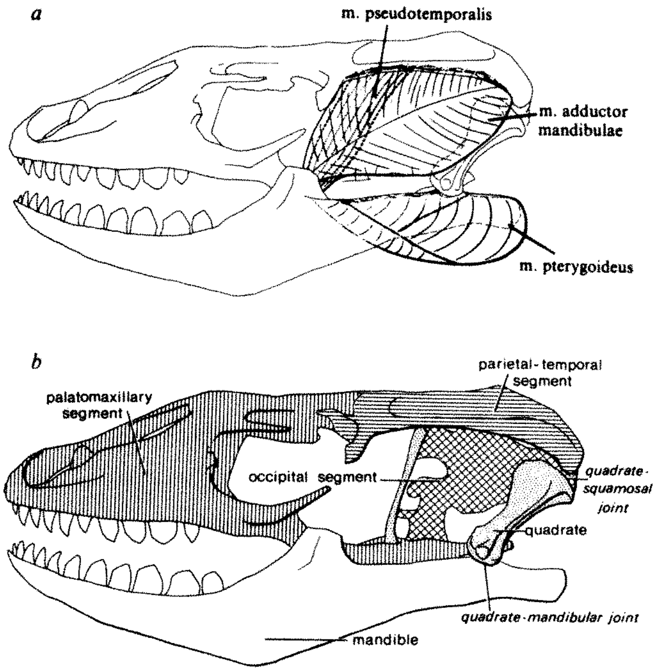

Fig. 1 *a*, Diagram of jaw adducting muscles in *Varanus exanthematicus*. The highly pinnate m. adductor mandibulae originates on the parietal-temporal and occipital units and inserts by means of a large central tendon on the coronoid region of the lower jaw. The m. pseudotemporalis originates from the anterior portions of the parietal-temporal and occipital units and inserts on the coronoid region medial to the m. adductor mandibulae. The m. pterygoideus originates on the pterygoid bone and passes ventrally and dorsally to insert on the ventral surface and retroarticular process of the mandible. This muscle, like the m. adductor mandibulae is highly pinnate, with many fibres running from the external aponeurosis of this muscle to the retroarticular process of the mandible. (For details see refs 1 and 2.) *b*, Bony structure of the lizard skull. The segments potentially important in lizard kinesis are indicated. Movement of the palato-maxillary unit relative to the parietal-temporal and occipital is termed mesokinesis, and that of the occipital unit relative to the parietal-temporal and palato-maxillary is termed metakinesis[6]. Movement of the quadrate at the quadrate-squamosal joint is termed streptostyly[6]. See text for further details.

Electromyographic recordings of the pterygoideus muscle show that it is active during all stages of feeding, including both ingestion cycles and 'power phases' when the animal is biting hard on food. Because it has been suggested that the pterygoideus is ineffective as a force-producing muscle, bite force was measured by stimulating this muscle electrically in an anaesthetised animal. The recordings indicated that the pterygoideus can produce a bite force at least equal to that of the adductor mandibulae externus.

0028-0836/80/080778—02$01.00

Previous studies of streptostyly[3,7–9,12,14] have, for the most part, assumed that it is most important during jaw opening and closing in cycles of ingestion and that its primary function is to produce anterior movement of the lower jaw. Further, movement of the quadrate is thought to be linked to movement of the maxillary segment.

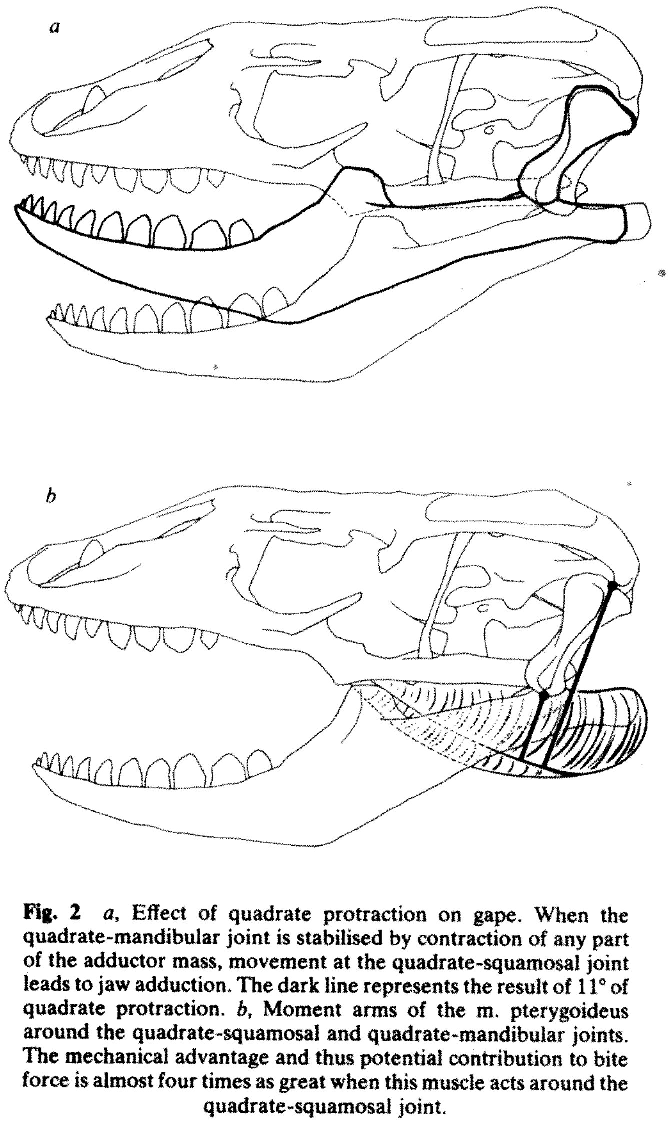

Fig. 2 *a*, Effect of quadrate protraction on gape. When the quadrate-mandibular joint is stabilised by contraction of any part of the adductor mass, movement at the quadrate-squamosal joint leads to jaw adduction. The dark line represents the result of 11° of quadrate protraction. *b*, Moment arms of the m. pterygoideus around the quadrate-squamosal and quadrate-mandibular joints. The mechanical advantage and thus potential contribution to bite force is almost four times as great when this muscle acts around the quadrate-squamosal joint.

Although the quadrate is potentially mobile in all the animals studied, streptostyly was observed only irregularly during cycles of jaw opening and closing in most animals. It was most regular in *Uromastix*. Streptostyly is independent of movement of the palato-maxillary segment (mesokinesis), as Throckmorton[3] found. This would be predicted by careful morphological examination of fresh specimens. In lizards, a ligament binding the quadrate to the pterygoid bone restricts posterior movement of the quadrate, but no such ligament restricts forward movement. Streptostylic quadrates are found in fossil lizards before the appearance of mesokinesis[12–14] and occur in animals with limited mesokinetic potential such as *Uromastix* and *Ctenosaura*. Streptostyly thus preceded and is independent of mesokinesis.

As an alternative to looking at the effect of streptostyly only when the jaw is opening, I note that protraction of the quadrate will close the jaws when the quadrate-mandibular joint is stabilised (Fig 2*a*). Contraction of any of the jaw adductors will lead to such stabilisation. In lizards, therefore, both the quadrate-mandibular and quadrate-squamosal joints are axes for jaw adduction. When an animal bites against resistance, little movement occurs at either joint, but both joints act as fulcra for the production of bite force. I suggest that streptostyly is not primarily important for the forward movement it imparts to the lower jaw, but for its contribution to jaw adduction during hard biting.

As pointed out above, contraction of the pterygoideus muscle leads to quadrate protraction. Figure 2*b* compares the mechanical advantage of the pterygoideus muscle around the quadrate-squamosal and quadrate-mandibular joints. Whereas the adductor mandibulae externus may produce power at the quadrate-mandibular joint, the pterygoideus muscle has primary mechanical advantage to act around the fulcrum at the quadrate-squamosal joint. Thus the significance of the quadrate-squamosal joint is that it allows a muscle with small mechanical advantage around the quadrate-mandibular joint to make a major contribution to bite force.

There are several functional implications of this two-joint jaw suspension system. During ingestion of food, when wide gape and fast movements are primarily important, movement around the quadrate-mandibular joint allows wide excursion of the mandible. However, when the animal bites against resistance, muscles act around both the quadrate-mandibular and quadrate-squamosal joints. The position of the pterygoideus muscle is such that it may produce fast closing around the quadrate-mandibular joint during ingestion and powerful adduction around the quadrate-squamosal joint during hard biting. With this two-joint system, the pterygoideus muscle avoids potential mechanical compromises between power and speed. Further, lizards with large pterygoideus muscles develop an effective force-producing muscle without interfering with gape. Increasing the size of the pseudotemporalis muscle would, for example, increase potential bite force, but the position of this muscle is such that gape would be severely restricted.

This scheme applies generally to all living lizards because they all have streptostylic quadrates, but is must be carefully applied to fossil reptiles. The rhyncocephalian, *Glevosaurus*, and the prolacertilians[12] possess an interrupted lower temporal arcade, but fused quadrate-pterygoid and quadrate-squamosal junctions. In neither of these forms is the quadrate free swinging or streptostylic. Only in the true Squamata, including early forms such as the Paliguanidae[14], *Kuehneosaurus*[12] and *Icarosaurus*[13] was the streptostylic condition achieved. In the lepidosaurian reptiles the lower temporal arcade has been lost at least three times independently; however, in many forms this loss is not related to quadrate mobility. As well as lizards, snakes and birds also have streptostylic quadrates, but their skull morphology is such that in morphological and functional detail there is little real equivalence in the three systems, and the scheme applied here does not apply.

Selective reconstitution of nude mice with long-term cultured and cloned specific helper T cells

R. Tees & M. H. Schreier

Basel Institute for Immunology, Grenzacherstrasse 487, Postfach, 4005-Basel, Switzerland

An antibody response is the end result of complex interactions among T cells, adherent cells and B cells[1-3]. An understanding of the interactions involved has proved difficult as pure populations of these cells have not been available. By making use of T-cell growth factor[4,5], we were able to grow normal helper T cells specific for heterologous erythrocytes[6]. Because specificity and mechanism of action of these cells had been demonstrated solely in culture, we sought to establish their competence in the whole animal. We have therefore examined here whether antigen-specific helper T cells, maintained in culture over long periods, would enable syngeneic nude mice to respond to T-cell-dependent antigens. The results show that specific helper T cells, propagated in serum-free medium *in vitro* for up to 15 months, can selectively and specifically reconstitute syngeneic C57BL/6J *nu/nu* mice. Depending on the specificity of the injected helper T cells, such nude mice could respond to sheep red blood cells (SRC) but not to horse red blood cells (HRC) and vice versa. The magnitude of the response was comparable to that of normal mice and could exceed it by almost 10-fold, depending on the source and number of injected helper T cells.

Table 1 documents the *in vitro* helper activity of the long-term cultured, cloned and subcloned helper T cells at the time of the present report. 10^3 to $10^{3.5}$ of these cells provided maximal T-cell help if added to 2×10^5 nude spleen cells in the presence of homologous antigen. A higher input of helper T cells rendered the culture medium acid and lowered the numbers of IgM plaque-forming cells (PFC). No PFC were induced in response to the unrelated antigen, indicating that these T cells were specific and that no polyclonal activation had occurred by day 5 of culture.

Injection of uncloned helper T cells (cultured over 3–4 months) with homologous antigen into syngeneic nude mice, induced a specific antibody response in these animals (Table 2). 5×10^6 HRC-specific uncloned helper T cells (LTC 15) gave rise to about five times as many direct PFC as could be expected in a primary response of normal mice 5 days after immunisation[7]. The simultaneous injection of the uncloned SRC-specific helper T-cell line LTC 25 and antigen (Table 2) gave rise to almost 10^6 direct PFC on day 5. The response to the unrelated antigen hardly exceeded background even when both antigens were injected at the same time (LTC 3, Table 2).

The unusually high response may reflect the lack of regulatory mechanisms in the nude mouse, such as 7S feedback inhibition[8] or the absence of suppressor T cells[9]. This is also indicated by the kinetics of the response. In contrast to normal mice, there was no sharp decrease in the number of PFC beyond day 5 after immunisation. Most reconstituted mice showed high or even increasing numbers of PFC up to day 7 after immunisation. Beyond that, the number of PFC varied considerably in individual mice before returning to background around 10 days after inoculation.

We have not determined what fraction of the injected helper T cells homes to the sites of antibody formation in the spleen. This aspect has an even stronger bearing on our reconstitution experiments with clones of helper T cells kept in continuous culture for up to 15 months. Table 2 shows results obtained with two of our clones and with one subclone (18/33/3). Although the number of PFC is somewhat lower than that obtained with uncloned helper T cells, it is still entirely comparable with the response of a normal mouse. The high degree of specificity remains unchanged. The antigen-independent anti-HRC response of subclone 18/33/3 (Table 2, last line) is under investigation.

The fact that a single clone of helper T cells can reconstitute a primary antibody response of normal magnitude raises the question of whether assumed restrictions in T-cell–B-cell interaction, operating at the level of idiotypes[10] or on a subset of cells[11], are compatible with our findings. It should be remembered that a nude spleen (on average 8×10^7 cells) contains at least 20,000 B-cell precursors, which can recognise the antigen SRC and are susceptible to T-cell help[12]. This minimal estimate does not account for antigen-specific recruitment of lymphocytes[13]. As 10^3 PFC can arise *in vitro* from one precursor within 5 days[12], it is obvious that the induction of less than 1% of B-cell precursors would be sufficient to give rise to about 10^5 PFC by day 5 after immunisation. Idiotypic analysis of the antibodies in normal and clonally reconstituted mice may provide critical information. Our preliminary results suggest that significant differences at the antibody level may exist between such mice. Thus, although the serum of the clonally reconstituted mice (18/33/3, Table 2) gave a haemagglutination end point when diluted 1 in 28,000, the average titres were significantly lower in mice reconstituted with uncloned specific helper T cells, even

Helper T cells were tested for helper activity and specificity in a specific *in vitro* helper assay[12]. 2×10^5 spleen cells from C57BL/6J *nu/nu* mice were cultured in a volume of 0.2 ml in flat bottom Falcon II tissue culture plates in the presence of 5×10^5 SRC or HRC and the indicated number of helper T cells. The culture medium was IMDM[15], supplemented with bovine serum albumin (1 mg ml^{-1}), human transferrin (30 μg ml^{-1}), soybean lipids (100 μg ml^{-1}) and cholesterol (50 μg ml^{-1})[12,15,16]. PFC were enumerated after 5 days in a modified Jerne plaque assay[17]. They are expressed as direct PFC per culture ± standard deviation of the mean. The helper T cells, specific for SRC or HRC (T'_{SRC}, T'_{HRC}) were obtained from spleens of lethally irradiated mice which had been reconstituted 7 days previously with thymocytes and injected with SRC or HRC (*in vivo* activated helper T cells (refs 12, 18)). They were cultured in the presence of antigen in Falcon 3013 tissue culture flasks in the same medium as described for the *in vitro* helper assay at a concentration of 10^6 activated T cells per ml. Antigen and irradiated syngeneic peritoneal cells (3,300R) were replenished at 1–2-week intervals. After 2–3 months of culture vigorous growth of cells was induced by supplementing the medium with partially purified T-cell growth factor[6]. The T-cell lines LTC15, 3 and 25 were subcultured and grown for another 3–4 months in TCGF-supplemented medium in the absence of antigen and peritoneal cells. Such T-cell lines were cloned (clone 18/19 and 1/25) and subcloned (18/33/3) in conditions of limiting dilution with a cloning efficiency of 5–20% (ref. 6). None of the T cells was exposed to antigen 3–4 months before the experiment.

18/19 Clone (T'_{HRC})	2×10^6	2	HRC	52,727 ± 14,978	274 ± 134
1/25 Clone (T'_{SRC})	5×10^6	4	SRC	485 ± 95	64,377 ± 4,919
18/33/3 Subclone (T'_{HRC})	5×10^6	4	HRC	159,100 ± 11,172	460 ± 254
	5×10^6	4	SRC	14,380 ± 1,951	965 ± 306

C57B1/6J *nu/nu* mice, 9th or 10th backcross (Institute for Biologisch-Medizinische Forschung, Füllinsdorf, Switzerland) were injected intravenously with long-term cultured or cloned helper T cells, together with 5×10^6 SRC and/or HRC. Five days later the number of direct PFC in the spleen, directed against either antigen, was determined in a modified Jerne plaque assay[17].

though the number of PFC per spleen was considerably higher (for example, LTC 25, Table 2).

At present, we know little about the long-term fate of these injected helper T cells *in vivo*. Boosting of mice which had been reconstituted with the SRC-specific clone 1/25 and primed 21 days earlier, gave rise to even higher numbers of PFC against the homologous antigen. This suggests that these helper T cells survive in the recipient animal. As nude mice cannot generate T-cell growth factor[19], an absolute requirement for T-cell proliferation[4,5], the reconstituting cells may revert there to a resting state. In the experiments presented here, we studied a few clones only, and have not observed a significant switch to IgG production. By using various clones and immunisation schedules, we should be able to decide whether the same helper T cell can provide help for various antibody classes.

Our results show that helper T cells reveal the same degree of specificity *in vitro* and *in vivo*. *In vitro*, these helper T cells are H-2 restricted, the restriction mapping to the left of the I-B region[14]. Reconstitution of T-cell-deficient mice with T cells selected and passaged in culture provides a new tool for studying the function and regulation of specific helper T cells, and should prove especially useful in discriminating between useful and misleading *in vitro* phenomena.

Vitamin B_{12} synthesis by human small intestinal bacteria

M. J. Albert, V. I. Mathan & S. J. Baker*

Wellcome Research Unit, Christian Medical College Hospital,
Vellore-632004, Tamil Nadu, India

In man, physiological amounts of vitamin B_{12} (cyanocobalamin) are absorbed by the intrinsic factor mediated mechanism exclusively in the ileum[1]. Human faeces contain appreciable quantities of vitamin B_{12} or vitamin B_{12}-like material presumably produced by bacteria in the colon[2], but this is unavailable to the non-coprophagic individual. However, the human small intestine also often harbours a considerable microflora[3–6] and this is even more extensive in apparently healthy southern Indian subjects[6]. We now show that at least two groups of organisms in the small bowel, *Pseudomonas* and *Klebsiella* sp., may synthesise significant amounts of the vitamin.

Bacteria were obtained by aspiration from the jejunum and ileum of healthy southern Indian control subjects, and patients with tropical sprue. All subjects gave their informed consent to the study and all had normal vitamin B_{12} absorption. Full details of the intubation, bacteriological techniques and vitamin B_{12} absorption tests have been described elsewhere[6]. Representative isolates of different groups of aerobic and anaerobic organisms were grown in the medium described by Nishio *et al.*[7] modified to support the growth of fastiduous organisms[8]. Vitamin B_{12} activity was measured in the presence of potassium cyanide by microbiological assay using *Euglena gracilis* Z strain[9] and *Ochromonas malhamensis*[10] as the test organisms. Descending paper chromatography was carried out in *sec*-butanol/acetic acid/water[11] and bioautography by the method of Linnel *et al.*[12].

Using the *Euglena gracilis* assay, the following groups of organisms were found to produce no detectable vitamin B_{12}-like material (the numbers in parentheses indicate the number of strains tested): enterobacteria (10), *Escherichia coli* (17), streptococci (18), *Neisseria* (5), staphylococci (4), aerobic lactobacilli (12), bifidobacteria (11), and *Bacteroides* (8). With the same assay, five groups of organisms produced considerable amounts of vitamin B_{12}-like material (Table 1). A subsample of these five groups of organisms were also tested using the *Ochromonas* assay (Table 1). Since the growth response of *Ochromonas* is more specific for vitamin B_{12} than that of *Euglena*[10], the material produced by the clostridia, *Veillonella* and *Fusobacteria* presumably consists of vitamin B_{12} analogues, whereas that produced by *Pseudomonas* and *Klebsiella* probably is biologically active vitamin B_{12}. This was further supported by chromatography and bioautography of the material produced by *Pseudomonas* which gave an R_f value identical to that of cyanocobalamin. A comparison of the whole broth and bacteria-free filtrates showed that in the case of *Klebsiella* the vitamin B_{12} activity was associated with the bacterial bodies but that with *Pseudomonas* the activity was principally free in the supernatant.

It has been shown that free intrinsic factor is often present in the lumen of the small intestine[13]. If these organisms also produce vitamin B_{12} *in vivo*, the free vitamin B_{12}, or that bound to bacteria, after undergoing liberation by digestive enzymes, could bind with the free intrinsic factor and, if absorbed, contri-

Fusobacteria	6	26.6	9.2–36.0	3	0	0–0

bute significantly to the vitamin B_{12} intake of the individual. For example, 10 ml of a culture of *Pseudomonas* would provide 0.14 μg of the vitamin which is more than the minimum daily dose of 0.1 μg which will produce a haematological response in subjects with vitamin B_{12} deficiency megaloblastic anaemia[14].

The vitamin B_{12} analogues produced by the bacterial isolates were not identified further. Those with no alteration in the corrin ring or benzimadazole moeity can also combine with free intrinsic factor[15,16]. However, since the amount of intrinsic factor passing through the intestine is in considerable excess of that needed to absorb the minimum daily vitamin B_{12} requirements[13], the appropriate analogues would have to be present in considerable amounts significantly to reduce the amount of intestinally produced vitamin B_{12} absorbed by normal subjects.

The role of intraluminal small intestinal bacteria in human vitamin B_{12} metabolism appears complex. Subjects with small intestinal bacterial overgrowth associated with a stagnant bowel syndrome, frequently have vitamin B_{12} malabsorption[17,18]. This malabsorption may often be reversed by the administration of broad spectrum antibiotics[18], suggesting that the defect is closely related to the bacterial overgrowth. However, the precise mechanism for the vitamin B_{12} malabsorption in these subjects is not clear. Various mechanisms have been suggested, including the bacterial uptake of vitamin B_{12} (ref. 19) or the intrinsic factor B_{12} complex[20,21]; alteration of the IF–B_{12} complex[22]; the production of toxins[23] which may affect the binding of the IF–B_{12} complex to the receptor[24]; and the production of large amounts of vitamin B_{12} analogues[25] blocking vitamin B_{12} absorption. In apparently healthy southern Indian subjects with normal vitamin B_{12} absorption there is frequently considerable bacterial colonisation of the upper small intestine[6], but the degree of bacterial overgrowth is not as great as in patients with a stagnant bowel syndrome with vitamin B_{12} malabsorption[26]. This fact, and the finding in the present study that some organisms produce predominantly vitamin B_{12}-like material (*Ochromonas malhamensis* growth factor) while others produce only vitamin B_{12} analogues (*Euglena gracilis* but not *Ochromonas malhamensis* growth factor), suggests that the quantity and type of the luminal flora may be important in determining the role of the intestinal bacteria in the vitamin B_{12} ecology of the individual.

In the light of the findings reported here, it is of interest that vitamin B_{12} deficiency among vegetarian Indians has been found with relatively high frequency in Indian immigrants in England[27–30], whereas it is uncommon among the same people in India with identical dietary patterns[31]. It is possible that in India these individuals have a bacterial flora in the small intestine which provides a significant proportion of their daily requirements of vitamin B_{12}, but when they move to a more protected environment the bacterial flora reverts to that characteristic of subjects living in western countries with little or no resident flora in the upper small bowel[3], the individuals lose their endogenous source of vitamin B_{12} and therefore become more prone to develop overt vitamin B_{12} deficiency.

We thank Mr S. P. Swaminathan for technical assistance. M.J.A. is in receipt of a senior research fellowship from the CSIR, New Delhi.

A factor(s) in *Klebsiella* culture filtrates specifically modifies an HLA-B27-associated cell-surface component

A. F. Geczy, Kerri Alexander & Helen V. Bashir

NSW Red Cross Blood Transfusion Service, 153 Clarence Street, Sydney, NSW, 2000, Australia

J. Edmonds

Rheumatology Department, The St George Hospital, Kogarah, NSW, 2217, Australia

We have previously shown[1,2] that a serum raised against certain isolates of *Klebsiella pneumoniae* lyses the lymphocytes of HLA-B27-positive patients with ankylosing spondylitis (AS) but not of B27-positive or B27-negative healthy controls. These observations suggested that some *Klebsiella* antigens cross-react with a gene product intimately associated with B27 or possibly with 'modified' B27 (refs 1, 3) in patients with AS. It seems likely therefore, that some *Klebsiella* antigens play a role in the pathogenesis of AS, perhaps by specifically modifying a B27-associated cell-surface marker. We have now examined the influence of culture filtrates from three *Klebsiella* isolates on lymphocytes from B27-positive and B27-negative healthy individuals. We report that 24-h culture filtrates of *Klebsiella* K43 (previously *Klebsiella* F19) contain a factor(s) capable of specifically modifying the sensitivity to anti-*Klebsiella* K43 serum of $B27^+AS^-$ lymphocytes (that is, cells not lysed by anti-*Klebsiella* K43 serum): 'modified' $B27^+AS^-$ lymphocytes are now serologically similar to the cells of B27-positive patients with AS ($B27^+AS^+$). The failure of anti-*Klebsiella* F10 and of anti-*Escherichia coli* sera to lyse lymphocytes, which have been incubated with the corresponding culture filtrates, excludes a nonspecific lysis by the anti-bacterial sera of target lymphocytes bearing bacterial antigens randomly distributed on their surface. Therefore, the data are compatible with a specific transformation by a *Klebsiella* K43-derived soluble factor of a B27-associated lymphoid cell component.

0028-0836/80/080782—03$01.00

Bacterial cultures were isolated from faecal and urine samples (*Klebsiella pneumoniae* K43, *Klebsiella* isolates F10, F12 and 462; *E. coli*) and from a wound swab (*Staphylococcus* sp.). Bacteria were grown in Tryptone soya broth (TSB, Oxoid) and killed by adding 0.25 ml of 40% formaldehyde to a 20 ml suspension of the organisms ($\sim 10^9$ per ml) in nutrient broth. The formalin-killed bacteria were washed twice with sterile 0.9% NaCl and stored at −20 °C. Antisera were raised in rabbits (3–5 kg) against formalin-killed suspensions of the bacteria as previously described[1]. Briefly, the animals were injected intravenously (i.v.) with about 10^9 bacteria in normal saline (2 ml) and 2 weeks later, intramuscularly with 10^{10} organisms in 2 ml complete Freund's adjuvant (Difco). Ten days later, the rabbits were boosted i.v. with 1 ml of bacterial suspension (10^8–10^9 organisms) in normal saline. Two weeks after the last injection, the animals were bled and the serum stored at −20 °C.

The results in Table 1 show that the lymphocytes of B27^{+}AS^{-} individuals, incubated for 24 h in TSB or with culture filtrates of *Klebsiella* F10, F12 or with *E. coli*, are not lysed by anti-*Klebsiella* K43 serum. Similarly, anti-*Klebsiella* K43 serum is not cytotoxic for the lymphocytes of B27^{-}AS^{-} or of B27^{-}AS^{+} individuals following a 24-h incubation with any of the bacterial culture filtrates. On the other hand, the strong reactivity to anti-*Klebsiella* K43 serum of B27^{+} cells from patients with ankylosing spondylitis (by Rome and New York criteria)[4] is preserved even when these cells are cultured for 24 h in the four different culture filtrates. By contrast, B27^{+}AS^{-} lymphocytes, incubated with culture supernatants of *Klebsiella* K43, become susceptible to lysis by anti-*Klebsiella* K43 serum but not by antisera to *Klebsiella* isolates F10, 462 or to *E. coli* and *Staphylococcus* sp. Furthermore, no 'extra' serologically-defined specificities are detected when *Klebsiella* K43-incubated B27^{+}AS^{-} cells were tested against a panel of antisera defining 13 HLA-A and 20 HLA-B specificities (results not shown). The transformation of B27^{+}AS^{-} lymphocytes appears to be a specific event and not a consequence of randomly-attached *Klebsiella* K43 determinants on the surface of B27^{+}AS^{-} cells. This conclusion is supported by the failure of anti-*Klebsiella* F10 serum to lyse lymphocytes incubated with culture filtrates of *Klebsiella* F10. As B27^{-}AS^{-} and B27^{-}AS^{+} lymphocytes are not

Table 1 Culture filtrates of *Klebsiella* K43* specifically modify a B27-associated cell surface component on the lymphocytes of B27-positive healthy individuals but not on the cells of B27-negative healthy controls; the lymphocytes of B27-negative patients with AS are also not modified

Incubation	Serum	Target lymphocytes B27^{+}AS^{-}	B27^{-}AS^{-}	B27^{-}AS^{+}	B27^{+}AS^{+}

Peripheral blood lymphocytes were obtained from groups of B27-positive normal controls (B27^{+}AS^{-}, $n = 19$), B27-negative normal controls (B27^{-}AS^{-}, $n = 17$), B27-positive patients with ankylosing spondylitis (B27^{+}AS^{+}, $n = 6$) and from B27-negative patients with ankylosing spondylitis (B27^{-}AS^{+}, $n = 3$). The cells were separated from heparinised blood by centrifugation in Ficoll–Paque (Pharmacia) for 25 min at 580*g*. The leukocyte band was removed and washed with RPMI 1640 medium (Flow) containing 2 ml heparin (1,000 units ml^{-1}), 10 ml IM HEPES (Sigma) buffer, 5 ml L-glutamine (200 mM) and 2 ml penicillin-streptomycin (5,000 IU, 5,000 μg ml^{-1}; Flow) per 500 ml of RPMI medium. The leukocytes were suspended in RPMI medium containing 10% human AB serum and centrifuged for a further 10 min at 180*g*. The cells were then resuspended in RPMI medium containing 20% human AB serum and adjusted to a cell concentration of 2.5×10^6 mononuclear cells per ml of medium. The incubation mixture consisted of 3.8 ml of cell suspension in RPMI containing 20% human AB serum and either 0.2 ml of TSB (Oxoid; diluted 1 : 2 with Dulbecco phosphate buffer (DPB) just before use) or 0.2 ml of culture filtrate (diluted 1 : 2 with DPB). Higher concentrations of culture filtrate were non-specifically cytotoxic to human leukocytes. Both the TSB and the culture filtrates were Millipore-filtered before dilution with DPB. The lymphocytes were incubated with TSB or with the various culture filtrates at 37 °C for 24 h. They were then washed twice with RPMI containing 10% human AB serum and resuspended at a concentration of 3×10^6 cells per ml. About 6×10^6 lymphocytes, suspended in 2 ml of RPMI containing 10% human AB serum, were labelled with 100 μCi of ^{51}Cr (0.1 ml; 200–500 μCi μg^{-1}, Amersham) for 60 min at 37 °C. The cells were then washed twice with RPMI + 10% AB serum and resuspended at a concentration of 3×10^6 cells per ml. One hundred μl of the ^{51}Cr-labelled cell suspension were added to 10 × 75-mm plastic tubes and incubated with 100 μl of antiserum at 24 °C for 30 min. Rabbit complement (100 μl) was then added to each tube and the incubation continued for a further 60 min. The cells were centrifuged at 2,000 r.p.m. for 15 min and 100 μl of the supernatant was counted in a Packard autogamma scintillation spectrometer. The amount of radioactivity in the samples was compared with radioactivity present in an equal volume of the supernatant from tubes containing cells in medium plus complement only, and with that present in tubes containing cells which had been lysed by the addition of 200 μl of Nonidet-P40. The results are expressed as the percentage of maximum ^{51}Cr released, which was calculated as follows:–

$$^{51}\text{Cr release } \% = 100 \times \frac{(\text{Radioactivity released by antiserum}) - (\text{Radioactivity released in absence of antiserum})}{(\text{Radioactivity released by NP-40-solubilised cells}) - (\text{Radioactivity released in absence of antiserum})}.$$

The results shown are of a representative experiment on the cells of single individuals for each category. All sera were tested undiluted. NT, not tested.

* *Klebsiella* K43 is a standard capsular designation; *Klebsiella* F10 and 462, antisera to which do not lyse B27^{+}AS^{+} lymphocytes, are two different isolates which have not yet been serotyped.

Table 2 Reactivity to anti-*Klebsiella* K43 serum of B27$^+$AS$^-$, B27$^-$AS$^-$ and B27$^-$AS$^+$ lymphocytes incubated with culture filtrates of *Klebsiella* K43

Diagnosis	B27-positive	No. transformed no. tested
Normal	Yes	17/19
Normal	No	0/17
Definite AS	No	0/3

Diagnosis was based on Rome and New York criteria. Cells are regarded as transformed if at least 50% are lysed by anti-*Klebsiella* K43 serum after incubation with K43 filtrate.

transformable by any of the *Klebsiella* culture filtrates tested, it appears that B27 or the product of a closely-linked gene is a specific target for a *Klebsiella* K43-derived factor(s).

Table 2 summarises the data on the reactivity to anti-*Klebsiella* K43 serum of B27$^+$AS$^-$, B27$^-$AS$^-$ and B27$^-$AS$^+$ lymphocytes incubated with culture filtrates of *Klebsiella* K43. The results indicate that none of the cells of B27-negative patients with AS nor of B27-negative normal controls is transformable by the *Klebsiella* K43-derived culture supernatant. However, two of the nineteen B27$^+$AS$^-$ cells have failed to be 'converted' by the *Klebsiella* K43 culture filtrate. It is apparent (Table 1 and Table 2) that only some strains of *Klebsiella* can trigger the specific transformation of B27$^+$AS$^-$ cells and it is possible that some individuals carry a 'subtype' of B27 which lacks a hypothetical receptor required to specifically bind a *Klebsiella* K43 antigenic determinant. This effect has also been demonstrated with another serotype of *Klebsiella* (K21; serotyped by Dr. I. Ørskov), indicating that the cross-reactivity of B27$^+$AS$^+$ cells with some strains of *Klebsiella* is not related to the capsular serotype of the organsim.

Although the chemical nature and mechanism of action of *Klebsiella*-derived factors are not yet understood, preliminary results indicate that they are non-dialysable but heat labile at 56 °C for 30 min. (results not shown).

Bacterial products have generally been shown to have a nonspecific influence on the immune response. Thus, culture filtrates and cell wall-rich fractions of *Listeria monocytogenes* contain substances that are mitogenic for B lymphocytes *in vitro*[5,6] while *in vivo* they, (1) function as immunologic adjuvants[7,8], (2) activate macrophages[5] and (3) induce a transitory state of nonspecific resistance to infection by live *Listeria*[5,9].

Furthermore, lipopolysaccharide, dextran sulphate, mycobacteria[10] and peptidoglycan[11] have been shown to be B cell-specific polyclonal activators of mouse lymphocytes. To our knowledge, the studies reported here represent the first demonstration that bacterial antigens may have a specific effect on HLA-associated gene products. It is tempting to suggest that the modification by environmental agents of specific cell surface components is an important step in the pathogenesis of the HLA-linked seronegative arthropathies.

This work was supported in part by a grant from the National Health and Medical Research Council of Australia. We thank Dr I. Ørskov (International Escherichia & Klebsiella Centre, Statens Seruminstitut, DK-2300 Copenhagen, Denmark) for serotyping *Klebsiella* K43 and K21 by means of the capsular Quellung reaction, Joan Yap for providing bacterial cultures, Nelly Coulits for technical assistance and the members of the NSW Branch of the Australian Rheumatism Association for allowing us to study patients in their care.

Covalent attachment of a progestational steroid to chick oviduct progesterone receptor by photoaffinity labelling

Leon S. Dure IV, William T. Schrader & Bert W. O'Malley

Department of Cell Biology, Baylor College of Medicine, Houston, Texas 77030

The chick oviduct progesterone receptor has been characterised and purified by us[1-3] and shown to consist of a mixture of two hormone-binding proteins[4,5]. These two proteins have equivalent ligand-binding sites, to which progesterone and other progestational steroids bind with high affinity ($k_{diss} = 10^{-9}$ M)[6,7]. Due to the noncovalent nature of this interaction, analysis of the proteins in denaturing or nonequilibrium conditions has always been hampered by ligand–protein dissociation during the experiments ($t_{1/2}$ = 12 h at 0 °C, 25 min at 37 °C)[6]. Efforts to use covalent attachment of steroids by alkylation or photoactivation have been largely unsuccessful, both for this protein and for other receptors[8]. However, covalent labelling of steroid isomerases[9] and an androgen-binding protein[10] has been obtained in reasonable yields using photoactivation of keto steroids containing multiple double bonds in conjugation with the ring-A ketone. We now report the first successful covalent attachment of a radiolabelled steroid to its receptor protein. The ligand chosen was a synthetic progestin, 17α,21-dimethyl-19-nor-pregn-4,9-diene-3,20-dione (R5020; Roussel-Uclaf)[11]. R5020 is available as the tritiated 17α-methyl derivative ($\geq$50 Ci mmol^{-1}) and has been used extensively for measuring mammalian progesterone receptors in normal[12,13] and neoplastic tissues[14,15]. This steroid was chosen for the photoaffinity study because its absorption maximum is at 320 nm, thereby allowing its activation by UV light at wavelengths above 300 nm, where protein damage would be minimised. The method should be generally applicable to other progestin receptors.

Oviduct cytosol from immature, oestrogenised chicks was prepared in buffer A (10 mM Tris-HCl, *p*H 7.4, 1 mM Na$_2$EDTA, 12 mM (1-thioglycerol) at 4 ml buffer per g tissue, as described previously[16]. The progesterone receptors were labelled with ^{3}H-R5020 at 2×10^{-8} M for 2 h at 0 °C. Then the hormone–receptor complexes were precipitated at 30% saturation of ammonium sulphate in buffer A and redissolved in a volume of buffer A equal to the original cytosol volume. Equilibrium binding studies showed R5020 binding to the progesterone receptor, as determined by (1) competition and displacement by authentic progesterone, (2) labelling of the same number of binding sites in the preparation by either labelled R5020 or progesterone and (3) chromatographic analysis of R5020–receptor complexes by DEAE-cellulose, gel filtration and sucrose-gradient ultracentrifugation. In all these tests, R5020–receptor complexes were indistinguishable from the complexes formed by authentic progesterone. Finally, binding of ^{3}H-R5020 to nonreceptor proteins (nonspecific weak absorption) was less than 5%.

Redissolved complexes were then photolysed at 0 °C in an ice bath using an 85-W low-pressure mercury vapour lamp (General Electric H85A3). Samples of receptor were placed in a beaker covered by a borosilicate glass plate to absorb UV below 300 nm. Aliquots (1.0 ml) were removed at intervals for up to 2 h.

Samples were tested initially for covalent steroid coupling by (1) addition of an equal volume of ice-cold 10% (w/v) of trichloroacetic acid (TCA). Precipitated protein was redissolved and counted for ^{3}H. There was a time-dependent increase in precipitable ^{3}H during UV illumination. Covalency was further

0028-0836/80/080784—03$01.00

assessed by (2) vigorous, repeated (five times) extraction with a 20-fold excess of diethyl ether, (3) gel filtration of irradiated samples in 5.0 M urea and (4) dialysis of the complexes against 1% (w/v) SDS. In all four types of test, UV-ray irradiation for 60 min resulted in optimal coupling of ^{3}H-R5020 to acid-insoluble material with a nominal coupling efficiency of 10–20% of the input ligand. Thus, the photoactivation reaction was indeed resulting in covalent attachment of the steroid to protein. We used electrophoresis in denaturing conditions by the method of Laemmli[2,3,17] to determine whether ^{3}H-R5020 was, in fact, attached to the desired receptors.

The results of these experiments are shown in Fig. 1. In *a*, three equivalent cytosol preparations (1.0 ml each) were complexed with ^{3}H-R5020, ^{3}H-R5020 plus a 100-fold molar excess nonradioactive progesterone, or ^{3}H-progesterone alone. Saturation studies not shown here indicated that this amount of ^{3}H-R5020 was sufficient to occupy about 20% of the available receptor sites. At this ratio, negligible binding of ligand to non-receptor protein is detectable by competition assays. Figure 1*a* shows that the ^{3}H-R5020 was coupled to two major species, as indicated by the arrows. This labelling was eliminated by the presence of nonradioactive progesterone, whereas general labelling of the rest of the gel was not inhibited by the competitor. Labelled progesterone did not couple significantly to proteins, as expected, at a wavelength of >300 nm, which is the cutoff wavelength of the borosilicate glass filter. Figure 1*a* also shows considerable radioactivity running near the dye front; this material runs several fractions ahead of the front and probably represents ^{3}H-R5020 derivatives bearing charged groups produced by photolysis.

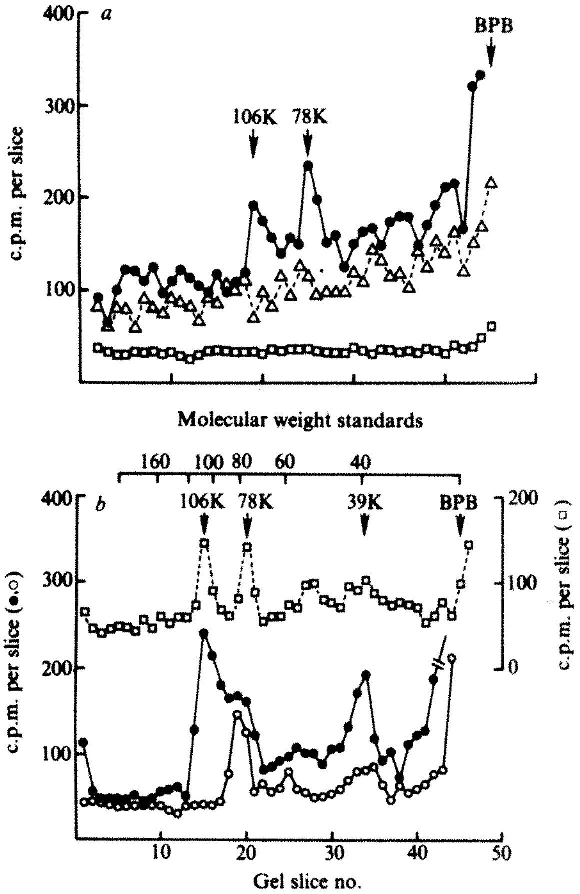

Fig. 1 Polyacrylamide gel electrophoresis of photolysed progesterone receptor preparations in denaturing conditions in 1% SDS by the method of Laemmli[17]. Total acrylamide monomer content was 7.5% in the separation gel. Gels were run in borosilicate glass tubes 6 mm × 10 cm, with 0.5-cm stacking gels. Electrophoresis of samples (10–100 µl containing 0.01% bromphenol blue tracking dye) was at 2.5 mA per gel until the dye front had travelled 10 cm. Gels were removed, sliced and minced using a Savant automated slicer and then counted for ^{3}H in Amersham-Searle ACS scintillation cocktail at 25% efficiency. *a*, Electrophoresis of three companion receptor samples after labelling, precipitation and UV-ray irradiation for 30 min as described in the text. Samples were labelled with ^{3}H-R5020 (●), ^{3}H-R5020 plus a 100-fold molar excess of nonradioactive progesterone (△), or with ^{3}H-progesterone (□). Arrows identify two major labelled species whose labelling was time and irradiation dependent. *b*, Molecular weight determination of the major photoaffinity-labelled ^{3}H-R5020–protein complexes. A standard MW curve was determined on companion gels as shown by the upper abscissa. Standards were 5 µg each of *Escherichia coli* RNA polymerase (165, 155, 95 and 39K bands), chicken conalbumin (86K), bovine serum albumin (68K) and chymotrypsinogen (26K). Protein bands were visualised by staining with Coomassie brilliant blue. Photolysed receptor–^{3}H-R5020 complexes were prepared by 60 min UV-ray irradiation followed by dialysis against buffer A and lyophilisation. The samples were then redissolved in 20% of the orginal volume of sample buffer containing 1% SDS, and subjected to electrophoresis as in *a*. Unfractionated receptors (□) were run as above or aliquots were chromatographed by stepwise KCl elution from DEAE-cellulose as described in the text to resolve receptor A and B proteins before electrophoresis. Two KCl steps were used: 0.15 M to yield protein A (○), and 0.3 M KCl to yield protein B (●).

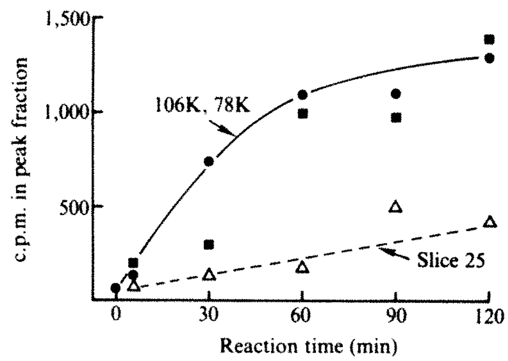

Fig. 2 Time course of photoaffinity labelling of progesterone receptors by ^{3}H-R5020. Chick oviduct cytosol was labelled for 120 min with 2×10^{-8} M ^{3}H-R5020 and then precipitated at 30% saturation of ammonium sulphate. The redissolved precipitate in buffer A was irradiated for the times indicated on the abscissa and then aliquots (1.0 ml) were frozen, lyophilised and subjected to SDS-polyacrylamide gel electrophoresis as described in Fig. 1 legend. The radioactivity in gel slices 13 (●), 18(■) and 25(△) are shown. These were the peak fractions corresponding to the labelled proteins of MWs 106,000, 78,000 and 39,000 respectively.

The extent of labelling seen on the gels was low, but consistent with the input noncovalent binding of ^{3}H-R5020 to receptor. For 150,000 c.p.m. ml^{-1} bound (by saturation analysis) and 10% efficient photoaffinity labelling (by TCA precipitation), the radioactivity which was recovered on the gels was about 50% of the theoretical value. This is a reasonably acceptable level when associated losses during transfer, dialysis and electrophoresis are considered.

We had shown previously[18] that the two progesterone-binding receptor proteins B and A had molecular weights (MWs) of about 115,000 and 79,000. Thus we determined the MWs of the two covalent ^{3}H-R5020 peaks by comparison with electrophoresis of protein standards. The results are shown in Fig. 1*b*. Again, two distinct radioactive peaks were seen with equivalent radioactivity in each. Their MWs were 106,000 and 78,000 in this experiment. A protein band in the preparation, migrating at 39,000 g mol^{-1} was also labelled significantly, as shown by the arrow at 39K. These results provided additional evidence that the labelled proteins were, in fact, the desired receptor subunits.

As a third test, a photolysed ^{3}H-R5020–receptor preparation was made and fractionated by DEAE-cellulose chromatography on a 3.0-ml column equilibrated in buffer A as described previously[4]. Stepwise KCl elution at 0.15 M specifically elutes receptor A purified about 80-fold over cytosol; subsequent elution at 0.3 M KCl elutes receptor B, purified about 200-fold over cytosol but contaminated with about 30% receptor A. Samples from 5-ml reactions were chromatographed, desalted by dialysis in buffer A and subjected to SDS-polyacrylamide gel electrophoresis. As shown in Fig. 1*b*, 0.15 M KCl elution of ^{3}H-labelled receptor A yielded the 78,000 g mol^{-1} peak on the SDS gel; 0.3 M KCl elution yielded a major species at

106,000 g mol^{-1}. In addition, a shoulder occurred at 78,000 together with an augmented peak at 39,000. Thus, the DEAE step had resolved the two higher MW protein bands as predicted from the chromatographic behaviour of receptors A and B proteins.

To test the saturability and extent of the photoaffinity reaction to these proteins, a time course study of UV-ray irradiation was carried out using an excess of ^{3}H-R5020 as the label, and aliquots (1.0 ml) were removed at various times. The samples were run individually on SDS-polyacrylamide gels by the method in Fig. 1; the peak fraction radioactivity of MW 106,000 and 78,000 were then plotted as a function of irradiation time. The results are shown in Fig. 2. The experiment shows a time-dependent covalent attachment of the label to the two receptor peaks, with a plateau at 1–2 h. Radioactivity in the peaks was now over 1,000 c.p.m., consistent with the use of additional input ligand. Significantly, both peaks became labelled at equivalent rates.

At least one additional peak of radioactive protein had been seen on the gels in Fig. 1, having a MW of about 39,000. It was possible that this was an additional receptor form, perhaps a proteolytic degradation product produced by an endogenous protease[19]. A hormone-binding intermediate in the digestion of the receptors has an apparent native MW of about 43,000 (ref. 20) Alternatively, the 39,000 g mol^{-1} peak could be simply a non-receptor protein which became labelled due to its weak affinity for the ^{3}H-R5020. Three types of test have been done which indicate that the latter alternative is the correct explanation. First, as shown in Fig. 1, radioactivity bound to protein on the gel in the low MW region was not competitively inhibited by simultaneous addition of nonradioactive progesterone. Thus, this 39,000 band was not a pre-existing receptor form present in the extracts. Second, in data not presented here, gels stained for protein with Coomassie brilliant blue showed a prominent band of protein at 39,000 g mol^{-1}, whereas the two higher MW bands did not coincide with stainable protein bands in these crude preparations. Thus, a potential contaminating protein of the proper mobility exists in the extracts. Third, Fig. 2 shows that the labelling kinetics of this 39,000 band differed markedly from that of the two receptor peaks. We therefore consider that the 39,000 band is probably a major protein contaminant, and becomes nonspecifically labelled with ^{3}H-R5020.

We conclude that the photolytic method adopted here covalently attaches steroid R5020 to both progesterone receptor proteins in yields of about 10%. Additional side reactions also occur, resulting in at least labelling of a 39,000 g mol^{-1} protein which is not receptor. This side reaction may arise as a consequence of photoactivation of the steroid; in the activated π^* state the ligand may bind less well to the receptor binding site and thus be released to interact with other proteins in the solution. As the 39,000 band protein is present in vast excess over the receptors, the efficiency of receptor–adduct formation in the system is very great compared with side reactions.

These studies thus provide direct physical determination of the MWs of the progesterone receptor components and provide additional evidence for the existence of two dissimilar hormone-binding subunits. As the ligand attachment is covalent, these labelled complexes should be ideal substrates for probing the hormone-binding site and as reagents in receptor radioimmunoassay. The receptor–labelling method should be generally applicable to other progestin receptors, including, for example, those of interest in breast tumours. Irradiation of tumour cells containing ^{3}H-R5020 in tissue culture may also be a practical method for studying the ultimate fate of nuclear receptor–hormone complexes.

Complete nucleotide sequence of immunoglobulin γ2b chain gene cloned from newborn mouse DNA

Department of Physiological Chemistry and Nutrition, Faculty of Medicine, University of Tokyo, Tokyo 113, Japan

Immunoglobulin heavy chain protein comprises five classes μ, γ, α, δ and ε chains which differ in amino acid sequences of the constant (C) region. The γ heavy chain class, which contains three domains and the hinge region, is divided into several subclasses such as γ1, γ2a, γ2b and γ3 in mouse. Amino acid sequence studies of mouse and human heavy chain proteins have shown that the γ subclass heavy chains are more closely related to each other than to the heavy chains of other classes. A similar conclusion was drawn from a nucleic acid hybridisation study using cDNAs complementary to the purified heavy chain mRNAs of the γ subclasses[1]. These results suggest that the immunoglobulin heavy chain genes of the γ subclasses have evolved by relatively recent gene duplication of the ancestral γ chain gene. The complete nucleotide sequence of the γ1 chain gene has demonstrated unequivocally that the domains and the hinge region are encoded in separate segments of DNA[2]. Partial nucleotide sequences of the γ2b chain gene indicated that the γ2b gene is interrupted by intervening sequences (IS) at locations homologous to those in the γ1 chain gene[3]. Comparison of the structures of these closely related genes would give new insights into evolution of eukaryotic genes and serve for understanding biological significance of various segments of the genes. We have now determined the complete nucleotide sequence of the immunoglobulin γ2b chain gene cloned from newborn mouse DNA. The sequence not only predicts the complete amino acid sequence of the γ2b chain but also demonstrates that the γ2b chain gene is interrupted by three intervening sequences at the junction of the domains and the hinge region.

The 6.6-kilobase *Eco*RI fragment coding for the C region of the immunoglobulin γ2b chain was previously cloned from newborn mouse DNA using λgtWES·λB as an EK2 vector[3]. The recombinant phage was referred to as λgtWES·IgH22 (abbreviated IgH22). The 6.6-kilobase fragment was isolated by agarose gel electrophoresis and ligated with the *Eco*RI-digested pBR322[4]. The hybrid plasmid was referred to as pBR322·IgH22 (abbreviated pIgH22). The detailed restriction

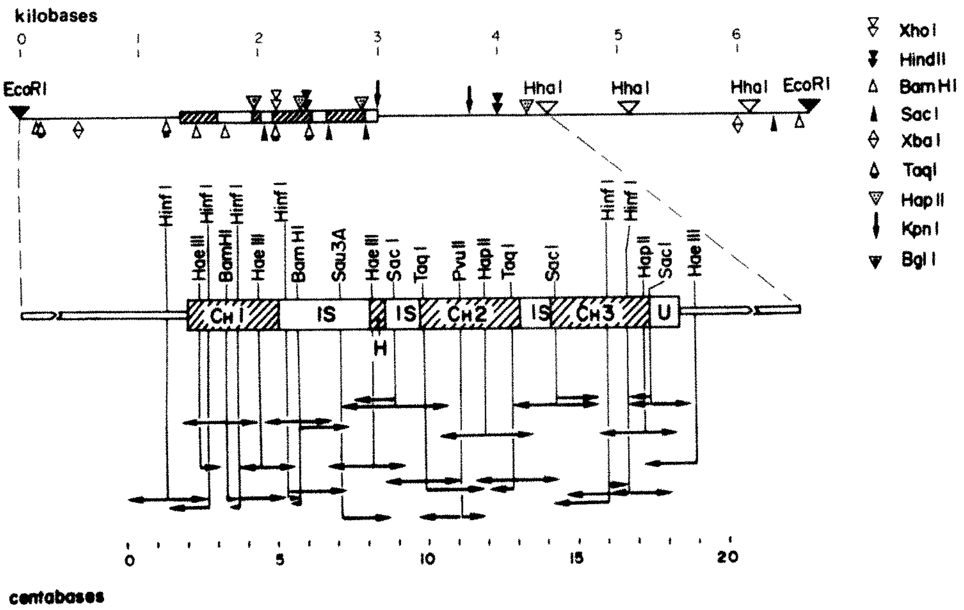

Fig. 1 Sequencing strategy of the mouse γ2b chain constant region gene. Plasmid DNA pIgH22 was purified according to the method of Clewell and Helinski[16]. Restriction cleavage sites were determined by combined cleavages of two or more enzymes. *Bam*HI, *Sac*I, *Xho*I and *Kpn*I sites were determined previously[3]. The 4.4-kilobase *Eco*Ri–*Hha*I fragment was isolated by 4% polyacrylamide gel electrophoresis after digestion of pIgH22 with *Eco*RI and *Hha*I, cleaved with other restriction enzymes and used as the substrates of phosphorylation. Alternatively, IgH22 was digested with either *Bam*HI or *Sac*I and resulting fragments were isolated. Each fragment was digested with the second restriction enzymes and used for phosphorylation. Sources of restriction enzymes were described previously[2]. The length of sequenced fragment is given in centabases in the 5′ to 3′ direction relative to the mRNA sequence. The horizontal arrows shown at the bottom indicate the direction and the extent of the sequence determined. The restriction map of the cloned 6.6-kilobase *Eco*RI fragment is presented on the top line. The restriction sites which were used for sequencing in the 4.4-kilobase *Eco*RI–*Hha*I fragment are shown on the rectangle below. The γ2b chain gene is represented by the wide rectangle. C_{H1}, C_{H2}, C_{H3}, domains of constant region; H, hinge region; IS, intervening sequence; U, untranslated sequence.

Fig. 2 Nucleotide sequence of mouse γ2b chain gene. The nucleotide sequence of the anti-coding strand is displayed 5′ to 3′. DNA sequencing was performed according to the method of Maxam and Gilbert[5]. DNA fragments to be sequenced were digested with the enzymes indicated in Fig. 1, treated with bacterial alkaline phosphatase (Boehringer) and phosphorylated using T4 polynucleotide kinase (New England Biolabs) and [γ-^{32}P]ATP (NEN). ^{32}P-DNA fragments were isolated by polyacrylamide gel electrophoresis and cleaved with second restriction enzymes. Fragments labelled only at one end were isolated by polyacrylamide gel electrophoresis and purified as described previously[2]. For strand separation the labelled DNA samples were dissolved in 100 μl of 0.2 M KOH, 10% (w/v) glycerol, 0.01% (w/v) xylene cyanol and 0.01% (w/v) bromphenol blue, heated at 37 °C for 1 min and separated with 15% or 20% polyacrylamide gel. Four base-specific reactions were utilised (G, A>C, C+T, C). Samples were loaded in 90% formamide and separated with thin gels (0.5 × 300 × 400 mm, 8 and 20% polyacrylamide gel). The amino acids predicted by the nucleotide sequence are shown above the coding sequences in italics. The partial amino acid sequences of MOPC 141[6] and MPC 11[7] are presented on the top line. Term, termination codon; poly (A), putative poly (A) addition site assigned by comparison with the mouse γ1 chain gene sequence. Amino acids are expressed by one letter code of A(Ala), C(Cys), D(Asp), E(Glu), F(Phe), G(Gly), H(His), I(Ile), K(Lys), L(Leu), M(Met), N(Asn), P(Pro), Q(Gln), R(Arg), S(Ser), T(Thr), V(Val), W(Trp) and Y(Tyr).

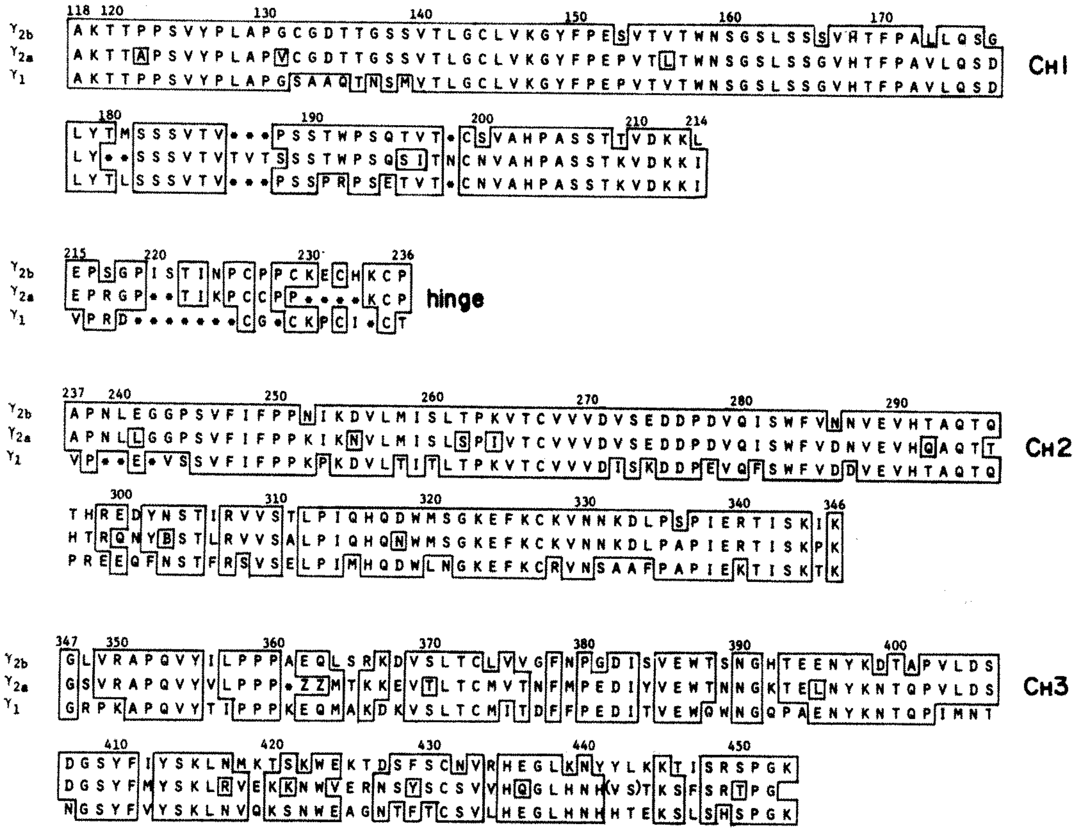

Fig. 3 Comparison of the amino acid sequences of γ1, γ2a and γ2b chains. The amino acid sequences of the γ1 and γ2b chains were predicted by the nucleotide sequences of the respective genes cloned from newborn mouse DNA[2]. The amino acid sequence of the γ2a chain was taken from the data of MOPC 173[7,8]. The residue was numbered with the first residue of C_{H1} domain as 118. Homologous positions are boxed. The one letter code used is as described in Fig. 2.

enzyme cleavage map of the *Eco*RI–*Hha*I fragment was constructed and the nucleotide sequence was determined by the chemical modification method of Maxam and Gilbert[5]. The restriction enzyme cleavage sites used for sequencing and the direction and range of sequencing are shown in Fig. 1.

The complete nucleotide sequence of the γ2b chain C region gene is shown in Fig. 2. The total number of the nucleotides determined is 1,834, which include the coding sequence, the IS, the 3′ untranslated sequence and the 5′ and 3′ flanking sequences.

The nucleotide sequence predicts the complete amino acid sequence of the C region of the γ2b chain (336 residues) which consists of the C_{H1} (residue 118–214), C_{H2} (residue 237–346) and C_{H3} domains (residue 347–453) and the hinge region (residue 215–236), respectively. The predicted sequence was compared with the partial amino acid sequences so far published, including 18 residues in the hinge region and the C_{H2} domain[6], 66 residues in the C_{H2} domain and 35 residues in the C_{H3} domain[7] (Fig. 2). The amino acid sequences derived from the nucleotide sequences matched the known amino acid

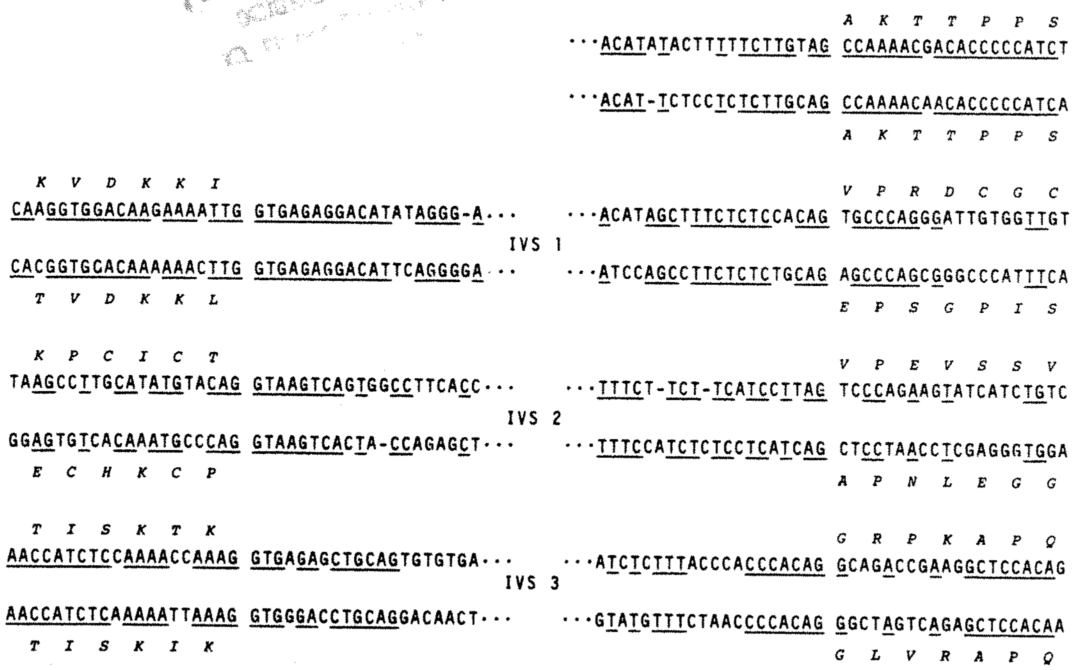

Fig. 4 Comparison of nucleotide sequences of the γ1 and γ2b chain genes around the junction of IS and coding sequences. Twenty nucleotides each of the homologous IS and coding sequences of the γ1 (upper sequences) and γ2b (lower sequences) chain genes are aligned to maximise homology. The top row is the 5′ end of the C_{H1} domain. The second, third and fourth rows are the 5′ and 3′ ends of the first, second and third IS, respectively. The nucleotide sequence of the strand corresponding to the mRNA is displayed 5′ to 3′ direction. The homologous nucleotides are underlined. Amino acids predicted from the nucleotide sequences are shown in italic letter by one letter code as described in Fig. 2.

sequences except two residues, Ser in place of Leu at residue 240 and Ser in place of Tyr at residue 268. To determine the junctions of the IS and coding sequences (see below) the nucleotide sequences were also correlated with the amino acid sequences of the γ2a chain[7,8] which share extensive homology with the known amino acid sequences of the γ2b chain[7].

The complete amino acid sequence of the C region of the γ2b chain is compared with the amino acid sequences of the γ1[2] and γ2a[7,8] chains as shown in Fig. 3. It is evident that the γ2b and γ2a chains show more homology to each other than to the γ1 chain. The results agree with our previous conclusion from cDNA–mRNA hybridisation studies[1]. The homology between the three γ chain subclasses (γ1, γ2a and γ2b) for each domain is calculated. The C_{H1} domains are most conserved (79–82%) throughout the three subclasses while the C_{H3} domains are least conserved (53–59%). The C_{H2} domains are highly conserved between the γ2a and γ2b chains whereas they are moderately conserved (63–68%) between the γ1 and γ2b (or γ2a) chains. The G + C content of the coding sequences is 52.3%, exceeding the value (41.8%) of the total mouse DNA[9].

Note that the nucleotide sequences predict an unexpected Lys residue at the carboxy terminus of the γ2b chain. Although most of the γ chains so far sequenced end with the Pro-Glys residues[10], the nucleotide sequences of the cDNA as well as chromosomal gene of the γ1 chain also predict an additional Lys residue at the end of the heavy chain[2,11]. These results suggest that the newly-synthesised γ2b chain proteins may have a Lys residue at the carboxy terminus, which will be removed eventually either at secretion or during circulation in the blood. It would be interesting to see whether the γ1 and γ2b chain proteins bound to the cellular surface have the Lys residue at their carboxy terminus since the amino acid sequencing was done using secreted immunoglobulins. The membrane-bound and secreted μ chains are reported to be different in the primary structures of their carboxy termini[12,13].

The comparison of the nucleotide sequences of the γ2b chain gene with the amino acid sequences of the γ2b and γ2a chains indicates that the domains and the hinge regions of the γ2b chain structural sequence are separated by three ISs as shown in Figs 1 and 2. The ISs split the γ2b chain gene at positions homologous to those in the γ1 chain gene[2,14]. The first, second and third ISs of the γ1 and γ2b chain genes as a pair are 356/316, 98/107, 120/112 base pairs long, respectively. The evolutionary significance of the ISs in immunoglobulin genes was discussed more extensively in previous reports[2,3].

The boundary sequences are compared between the γ1 and γ2b chain genes (Fig. 4). The first 10 nucleotides at each end of the ISs are highly conserved, although not identical, between the two genes whereas there is considerable divergence of the overall nucleotide sequences of the homologous IS. The possibility is discussed that not only nucleotide sequences at the joints of the IS and structural sequences but also other signals such as secondary and tertiary structures of mRNA precursors may be important for the recognition of splicing[15].

We thank Dr Y. Mano for his encouragement. This investigation was supported in part by grants from the Ministry of Education, Science and Culture of Japan.

A novel fragment of the corticotropin-β-lipotropin precursor

Rolf Håkanson*, Rolf Ekman†, Frank Sundler‡ & Roland Nilsson†

Departments of Pharmacology* and Histology‡, University of Lund, Lund, Sweden, and Department of Clinical Chemistry†, University of Lund at Malmö General Hospital, Malmö, Sweden

The pituitary ACTH/MSH cells are virtual storehouses for biologically important peptides. In addition to corticotropins, melanotropins, opioid peptides and lipolytic peptides these cells contain large amounts of at least three different polypeptides (or small proteins) having tryptophan in the amino-terminal position (Trp-peptides)[1–3]; their approximate molecular weight (MW) has been given as 14,000 (ref. 4). Nothing is known of their chemical properties and physiological significance. Experimental data indicate that the Trp-peptides in the ACTH cells are stored in the secretory granules[3] to be released jointly with ACTH and other secretory products, such as β-endorphin and/or β-lipotropin (β-LPH)[6]. ACTH and β-LPH are formed from a large common precursor protein where they constitute the carboxy-terminal portion[7–14]. Together the two peptides account for one-third to one-half of the molecular weight of the precursor and there has been considerable interest in the primary structure and possible physiological significance of the remaining amino-terminal portion[15]. The fact that the Trp-peptides occur in conspicuously high concentrations in the secretory granules of the ACTH/MSH cells prompted an investigation into their relation to the ACTH-β-LPH precursor protein. We have now isolated a glycopeptide with an apparent MW of ~11,000 residing in the secretory granules of the ACTH/MSH cells from pig pituitary. The amino acid sequence of its amino-terminal part was found to be identical with the amino-terminal end of the bovine corticotropin-β-LPH precursor protein[16]. We propose that the isolated new fragment is identical with the amino-terminal portion of the precursor that remains after ACTH and β-lipotropin have been split off.

Acetone powder was prepared from fresh frozen pig pituitaries and extracted with hot saline. The *p*H of the extract was adjusted to 3.9, the resulting precipitate was spun down and the supernatant was dialysed and freeze-dried (Table 1). The freeze-dried material was chromatographed on a DEAE-Sephadex column. The Trp-peptides could be separated into several peaks, the three major ones were labelled I, II and III (Fig. 1*a*). Each of the three Trp-peptides were further purified by gel chromatography (Fig. 1*b*). As a result, all of them appeared highly purified but only peptide I satisfied the criteria for complete homogeneity as judged by SDS-gel electrophoresis (Fig. 1*c*) and amino-terminal analysis. Tryptophan was identified as the amino-terminal amino acid (see below).

An antiserum was raised against peptide I. In a radioimmunoassay system this antiserum cross-reacted weakly with β-LPH and not at all with ACTH, α-MSH, β-MSH, β-endorphin or $\beta\text{-LPH}_{39-45}$. The antiserum was used to localise peptide I in the pituitary by immunohistochemistry. The results confirmed our previous fluorescence histochemical finding[3] that the Trp-peptide resides in the secretory granules of the ACTH/MSH cells (Fig. 2).

Peptide I was not recognised by antisera either to ACTH_{1-24} (ACTH radioimmunoassay kit, Amersham Radiochemical Centre) or to α-MSH (ACTH_{1-13}) which suggests that neither ACTH nor α-MSH is contained within its structure.

The amino acid sequence of the 1–35 portion of the amino-terminal end of peptide I was: Trp-Cys-Leu-Asp-Ser-Ser-Gln-Cys-Gln-Asp-Leu-Ser-Thr-Glu-(?)-Asn-Leu-Leu-Ala-Cys-Ile-Arg-Ala-Cys-(?)-Pro-Asp-Leu-Ser-Ala-Glu-Thr-Pro-Val-Phe. Comparison of the identified amino acid sequence with that of previously identified peptides and proteins showed it to correspond almost exactly to that recently predicted by Nakanishi *et al.*[16] for the amino acid sequence −105 to −71 of the ACTH-β-LPH precursor (Fig. 3). The prediction was based on nucleotide sequence analysis of cloned cDNA encoded by mRNA from bovine pituitary intermediate lobe. Our results differed from the prediction in position −102 where we found Asp instead of Glu, and in position −94 where we found Ser instead of Thr. These differences may be ascribed to the fact that the predicted amino acid sequence was based on a bovine nucleotide sequence whereas we have used porcine material. Since immunochemical analysis indicated that neither ACTH nor α-MSH are contained within the structure of peptide I and since the prediction has readily hydrolysable Lys-Arg in position −2 and −1 connecting with ACTH (ref. 17), it appears likely that the carboxy terminus corresponds to position −3 in the predicted ACTH-β-LPH precursor (Fig. 3). The amino acid composition of peptide I is given in Table 2. The presence of galactosamine and glucosamine residues suggests that peptide I is glycosylated. This finding is consistent with the observation that the ACTH-β-LPH precursor is a glycoprotein[18].

The remarkable similarities in amino acid sequence between the amino-terminal portion of peptide I and a part of the predicted ACTH-β-LPH precursor make it highly probable that peptide I is a fragment of the ACTH-β-LPH precursor. In addition, we propose that the isolated Trp-peptide exists as such in the secretory granules of the ACTH/MSH cells. It seems unlikely that the peptide is generated by cleavage at the Trp position during the process of purification, because specific fluorescence histochemical analysis has revealed the presence within these cells of extremely large amounts of polypeptides (or small proteins) having tryptophan at the amino terminus[1–3]. Thus, we believe that peptide I is a naturally occurring fragment of the ACTH-β-LPH precursor. The carboxy terminus of peptide I probably corresponds to position −3 in the ACTH-β-LPH precursor. If so, peptide I is the amino-terminal portion

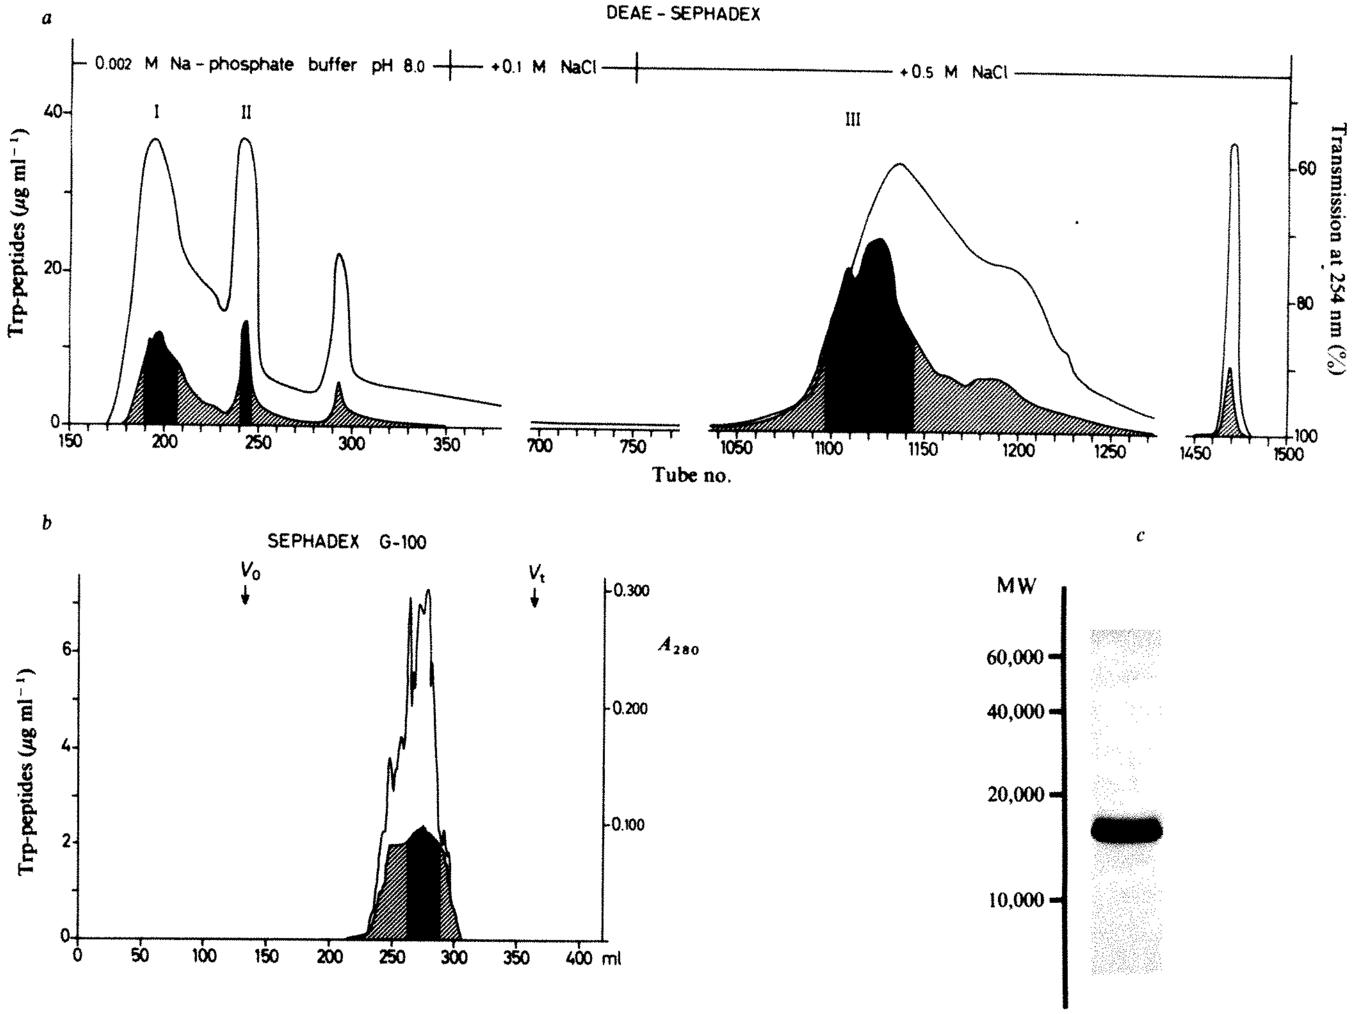

Fig. 1 *a*, Chromatography on a DEAE-Sephadex A-25 column (gel bed height 160 cm, diameter 5 cm) equilibrated with 0.002 M Na-phosphate buffer, *p*H 8.0. Freeze-dried extract of pig pituitaries (see Table 1) was dissolved in the buffer and applied to the column (3 g in 30 ml). The column was developed with the dilute phosphate buffer. Fractions of about 4 ml were collected. After the appearance of non-adsorbed proteins the elution buffer was enriched first with 0.1 M NaCl and then with 0.5 M NaCl. The stippled area shows the elution pattern of the Trp-peptides, measured fluorometrically[24]. The material collected for further purification is indicated in black. Peaks I, II and III were dialysed against redistilled water for at least 48 h and freeze-dried. The lyophilised material in peak I weighed 135 mg and was purified 5.3-fold compared with the acetone powder in Table 1. It was taken up in 0.1 M formic acid to a concentration of 50 mg ml^{-1} and applied to a Sephadex G-100 superfine column (gel bed height 90 cm, diameter 2.5 cm) equilibrated with 0.1 M formic acid, which was also used for elution (*b*). Fractions of 4 ml were collected and analysed for Trp-peptides. V_0 is the void volume defined by the use of blue dextran. V_t is the total mobile phase defined by the use of ^3H_2O. The weight of the purified material after dialysis and freeze-drying was 40 mg (Trp-peptide I). It was purified 6.2-fold. *c*, SDS-polyacrylamide (12.5%) gel electrophoresis of the isolated Trp-peptide (peptide I) was performed in a discontinuous system according to the method of King and Laemmli[30]. Samples were pretreated with 0.1 M 2-mercaptoethanol and heated at 90 °C in the presence of 1% SDS for 3 min. Separations were carried out in a Pharmacia apparatus GF-4 and proteins and peptides were stained with Coumassie brilliant blue R-250. The approximate molecular weight scale was deduced from the positions of nine standard proteins. The molecular weight of the isolated peptide appears to be over 15,000. This assessment, however, does not take into consideration the possibility that the peptide is rich in basic amino acids and/or glycosylated which may result in overestimation of the molecular weight.

Table 1 Recovery and yield of Trp-peptides in the initial purification steps

Preparation	Weight (g)	Protein (g)	Trp-peptides (mg)*	Calculated yield of Trp-peptides (%)	Relative purification† (-fold)
Acetone powder	225	140	150	100	1
Saline extraction (95–100 °C)	—	16	60	40	3.5
Precipitation at *p*H 3.9	13	10	50	33	4.7

One kg frozen pig pituitaries was homogenised in 10 l of cold acetone and left overnight. The resulting precipitate was washed with 40 l acetone and with 20 l acetone-diethyl ether (1 : 1) and finally with 20 l diethyl ether. The dried acetone powder was extracted with 4 l hot saline (95–100 °C) for 10 min. After cooling to 4 °C and centrifugation at low speed the *p*H of the supernatant was adjusted to 3.9 by the dropwise addition of 1 M HCl. After boiling for 3 min, the resulting precipitate was spun down and discarded, and the supernatant was dialysed against several changes of re-distilled water (at least 48 h) and freeze-dried. The concentration of Trp-peptides was determined fluorometrically with tryptophyl-alanine as standard[24]. Values are means of four separate runs. Protein was measured according to the method of Lowry *et al.*[25].

* Peptide weight expressed in terms of weight-equivalents of tryptophyl-alanine.

† Purification calculated from the ratio of μg Trp-peptides over mg protein.

that remains after β-LPH, ACTH, and the connecting Lys-Arg pair have been split off[17].

The prediction of the amino acid sequence of the ACTH-β-LPH precursor does not identify the amino terminus with certainty. Met in position −131 was considered a likely location for the translational initiation site[16]. We propose that the amino terminus of the precursor, following removal of the signal peptide, is Trp in position −105 (Fig. 3). It is probable that the amino acid sequence from −131 to −106 constitutes the signal peptide which is included in the primary translational product but lost upon packaging in the secretory granules. Hence, the granule-stored amino-terminal fragment of the porcine ACTH-β-LPH precursor consists of 103 amino acid residues and has a molecular weight of approximately 11,000 (Table 2).

The ACTH-β-LPH precursor (239 amino acid residues, MW ~26,000) generates β-LPH, ACTH and peptide I through enzymatic hydrolysis of consecutive basic residues[17]. Based on the occurrence of such consecutive basic residues within the precursor molecule other points of cleavage can be postulated.

Table 2 Amino acid composition of peptide 1

Residue	Residues determined*	Residues calculated to the nearest integer	Residues expected from predicted amino acid sequence −105 to −3
Lys	3.5	4	3
His	0.9	1	1
Arg	7.2	7	9
Asp	9.4	9	11
Thr	3.5	4	5
Ser	8.4	8	8
Glu	12.7	13	15
Pro	8.1	8	8
Gly	15.9	16	13
Ala	8.1	8	7
Half-cystine	6.6	7	4
Val	3.0	3	5
Met	1.1	1	1
Ile	1.4	1	1
Leu	7.1	7	6
Tyr	1.3	1	1
Phe	3.2	3	3
Trp†	1.5	2	2
Glucosamine	2.5	++	0
Galactosamine	0.6	+	0

Amino acid analyses were performed by hydrolysing samples of peptide I (100–200 μg) in 0.5 ml of boiling 5.7 M HCl at 110 °C for 24 and 72 h in sealed evacuated tubes. The hydrolysates were analysed according to the two column method of Spackman *et al.*[26] in a Durrum D-500 amino acid analyser. Carbohydrates were estimated on the hydrolysed samples. Half-cystine was determined as cysteic acid and methionine as methionine sulphone after performic acid oxidation[27]. Tryptophan was determined after hydrolysis in methanesulphonic acid[28] and before hydrolysis by a spectrophotometric method[29].

* All values are given in residues per 103 residues total amino acids (values for amino sugars and ammonia not included in summation). 103 is the number of residues expected from the predicted amino acid sequence −105 to −3. The calculated molecular weight of the peptide sequence is approximately 11,000.

† With both methods of determination the number of tryptophan residues was between 1 and 2.

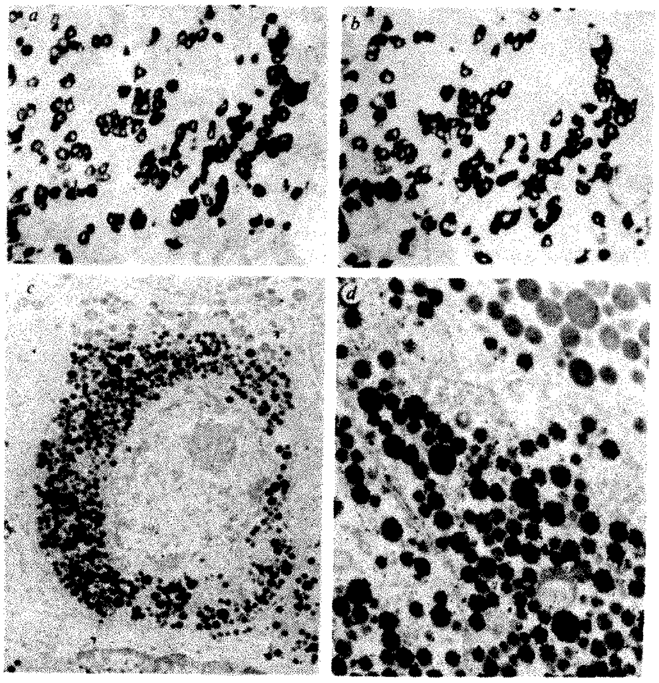

Fig. 2 Immunostaining of cells in the pig pituitary (anterior lobe) using antiserum to Trp-peptide I (*a*) and ACTH (ref. 3) (*b*). Three rabbits were immunised with peptide I by subcutaneous injection (multiple site) of the antigen (200 μg) emulsified with 1 ml of Freund's adjuvant. Booster injections were given 4 weeks later. Satisfactory antibody titre for radioimmunoassay (1 : 1,000) was obtained in one of the rabbits 2 weeks after the second injection. The cells displaying peptide I immunoreactivity were identical with the ACTH cells as shown by immunostaining consecutive plastic sections. Formaldehyde-fixed tissue was embedded in Epon. Sections, 1-μm thick, were exposed to either of the two antisera (each in dilution 1 : 320) for 24 h at 4 °C. The site of antigen-antibody reaction was identified by the peroxidase-antiperoxidase method of Sternberger[31]. The intracellular storage site of peptide I was established by electron immunocytochemistry (*c*, *d*). Note intense immunostaining over all secretory granules of the ACTH cell. Non-reacting cell (probably GH cell) in upper right corner of *d*. (*a* and *b* ×220; *c* ×3,100; *d* ×9,900.)

ACTH may yield α-MSH (ACTH_{1-13}) and CLIP (ACTH_{18-39}). β-LPH yields γ-LPH ($\beta\text{-LPH}_{1-58}$) and β-endorphin ($\beta\text{-LPH}_{61-91}$). The amino-terminal part of the precursor (peptide I) may yield a smaller Trp-peptide (residues −103 to −58), γ-MSH (residues −56 to −43) and a carboxy-terminal fragment (residues −41 to −1) (Fig. 4).

The fact that the isolated amino-terminal part of the ACTH-β-LPH precursor exists as such in the secretory granules of the ACTH/MSH cells and that it is released together with other secretory products upon stimulation[6] makes it tempting to speculate that it exerts a physiological function in the circulation. Some preliminary tests of bioactivity have been performed. The melanotropic activity, tested in a bioassay system[19], was such that 1 μg of the Trp-peptide gave the same response as 3.4×10^{-3} μg α-MSH (Sigma). This probably reflects the His-Phe-Arg-Trp sequence (−51 to −48) which is known to carry melanotropic activity[20]. The peptide had weak lipolytic activity on isolated rabbit adipocytes[21]; 1 μg of the peptide gave about the same response as 10^{-2} μg β-LPH. The peptide had no

Fig. 3 The predicted amino acid sequence of the amino-terminal portion of the bovine ACTH-β-LPH percursor after ACTH and β-LPH have been split off (according to Nakanishi *et al.*[16]). The amino acid residues are numbered in the direction from amino terminus to carboxyl terminus, with the first residue proximal to ACTH given as no. −1; being on the NH_2-terminal side of ACTH all the residues are indicated by negative numbers (see ref. 16). Amino acid residues in boxes represent the identified primary structure of the Trp-peptide isolated from pig pituitary. Amino acid sequencing[32] was made with a Beckman sequencer (model 890 C) using the standard Beckman 1 M Quadrol program (Beckman 122974) with polybrene to retain the peptide[33,34]. Phenylthiohydantoin (PTH) derivates were identified by high-pressure liquid chromatography on a 30-cm Waters μ-Bondapak C18 column by using stepwise elution with a system with methanol-containing buffers (Waters Associates) for the ethylacetate phases and a 60/40 mixture of methanol and 0.01 M sodium acetate for the aqueous phases. TLC on fluorescent silica gel plates was used as an additional method of identification[35]. Moreover, PTH-carboxy-methylcysteine residues were identified by radioactive labelling.

adrenocorticotropic activity when tested *in vivo*[22], and it did not cause displacement of naloxone in an opiate receptor-ligand assay[23]. The functional significance of peptide I and of the other pituitary Trp-peptides (which may well be fragments of peptide I) remains to be established.

After submission of this paper, Keutmann *et al.*[36] described the partial purification from mouse pituitary tumor cells of a glycoprotein accounting for most of the non-ACTH, non-β-LPH region of the ACTH-β-LPH precursor. The amino terminus was found to be tryptophan.

The sequencing data are available from the authors on request. We thank Dr David Eaker for determining the amino acid composition, Dr Leonard Larsson for performing the assay of melanotropic activity, Dr Per Melin (Ferring AB) for performing the assay of adrenocorticotropic activity and Professor P. Schwandt for assaying the lipolytic acitivity. Antiserum against α-MSH was a gift from Dr D. Swaab. The investigation was supported by grants from the Swedish Medical Research Council (04X-1007) and from the Medical Faculty of Lund, Lund, Sweden.

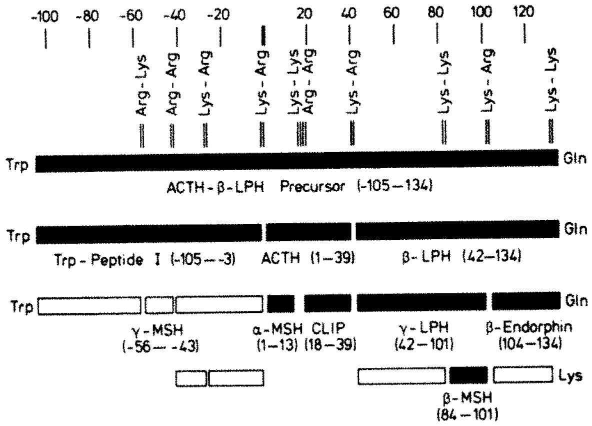

Fig. 4 The proposed ACTH-β-LPH precursor protein (putative signal peptide not included) and the various fragments that may be generated from the precursor by proteolytic processing, assuming a protease specific for consecutive basic residues[17] acting on the many pairs of Arg or Lys (indicated in the figure) connecting the component peptides in the precursor molecule. Identified or postulated fragments are shown in black in contrast to purely hypothetical fragments.

Recovery frequency of phages λ and M13 from human and animal faeces

Susan A. Schluederberg, Bonnie Marshall, Chikanori Tachibana & Stuart B. Levy

Tufts University School of Medicine, Boston, Massachusetts 02111

Derivatives of bacteriophages λ and M13 are in common use as vectors in recombinant DNA research[1–5]. These laboratory-derived phages have been designed to allow cloning of DNA fragments, but to be unable to survive outside a defined laboratory and/or host-cell environment. To assess the availability of wild-type λ or M13 phages in the environment which might potentially rescue debilitated derivative phages, we have now examined the frequency of these and other bacteriophages in human and animal faeces. We detected coliphage in over two-thirds of the faecal samples. Of these, 1.2% of the samples contained λ-like phage and 3.5% had phage indistinguishable from M13.

Bacteriophage λ was originally discovered as a prophage in *Escherichia coli* K12 by Lederberg[6]. It has been the subject of extensive genetic and molecular studies. The Charon phages 3A, 4A and 16A are derivatives of λ which have been certified for recombinant DNA studies in an EK2 system[7] when they are grown in debilitated *E. coli* K12 DP50 or DP50 *supF* (ref. 1).

0028–0836/80/080792—03$01.00

Another derivative of phage λ, λ·gt WES B (refs 2, 3), was produced by introducing amber mutations and other modifications into phage λ·gt·λC (ref. 4). It has also been certified as an EK2 vector when grown in *E. coli* K12 DP50 supF. M13 is a male-specific DNA phage originally isolated by Hofschneider[8] from a strain of *E. coli*. Derivatives of this phage have been produced for use as cloning vehicles[5].

Table 1 *E. coli* strains studied

Strain	Relevant characteristics	Source
D0-27	*E. coli* $C\lambda^s$, F^-	M. Malamy
D0-28	*E. coli* $C\lambda^s$, F^- nal^R	This laboratory*
D0-29	*E. coli* $C\lambda^R$ mal^- F^- nal^R	This laboratory†
B0-11	*E. coli* $C\lambda^R$ nal^R F^+	This laboratory
U-7	*E. coli* K12 HFr (λ^+)	M. Malamy

* Nalidixic acid resistant mutants of D0-27 were isolated without mutagenesis after heavy inoculate plating on MacConkey agar containing 30 $\mu g\ ml^{-1}$ nalidixic acid.

† A spontaneous, λ resistant mal^- derivative of D0-28. Resistance to λ was confirmed by inability of λ^{vir} to grow.

In our study, four populations of humans were sampled—hospital patients, personnel from clinical and research laboratories, first-year medical students living in the Boston area (urban), and people residing in Sherborn, Massachusetts (rural). Animals from a farm in Sherborn, 20 miles west of Boston, were also sampled. Faecal specimens were collected on sterile 'Culturettes' (Scientific Products) and streaked onto MacConkey plates. Phage assays were carried out as described in Table 2 using strains listed in Table 1. During the initial screening process, the presence of phage λ was detected by identifying those plaques on strain D0-28 (*E. coli* $C\lambda^s$, F^-) which did not appear on strain D0-29 (*E. coli* $C\lambda^r$, F^-). The presence of M13 was detected by its ability to form plaques on strain B0-11 (*E. coli* C, F^+), but not on D0-29.

Among the 303 samples tested in both studies, phage were detected at an average frequency of 69% (Table 2). The highest percentage of samples with phage was found in the urban and laboratory groups. This finding agrees with a recent report[9] that urban sewage yielded a higher concentration of phages than rural sewage. Phage isolates suspected of being λ were tested for DNA homology with known λ phage using DNA·DNA filter hybridisation[10] to ^{32}P-labelled λ55 (ref. 11). In addition, the plaque isolates were tested for their ability productively to infect λ-lysogenic *E. coli*. Homoimmune λ-like phages should produce no plaques on λ-lysogenic *E. coli* due to the immunity conferred on lysogenic cells by the λ repressor. By the above criteria, only 2 of the 162 samples (frequency 1.2%) contained bacteriophage which were indistinguishable from λ. They came from a rural housewife and one of the laboratory personnel.

The M13 isolates formed turbid plaques on the F^+ indicator strain (B0-11), but no plaques on the F^- strain (D0-28). To confirm that these isolates were M13, each was hybridised[10] to a ^{32}P-labelled RF M13. This probe was made by nick translation[12] of RF DNA. Additional confirmation that the plaques were M13 came from agarose gel electrophoresis of supernatants from phage-infected cells in which the DNA was easily detected by ethidium bromide staining of the gels (L. Laverne, J. Hines and D. Ray, personal communication). Each M13 isolate collected from a productive infection of B0-11 showed a mobility identical to native M13 (Fig. 1). Furthermore, suspected M13 phages were neutralised by antiserum directed against the M13 coat protein.

M13-like phages were recovered in 5 out of the 141 samples (3.5%) from humans. The highest frequency was found in hospital (9.1%) and rural (farm) (5.9%) samples. M13 was detected at the same frequency (5.9%) in samples from farm mammals, but was not recovered in chicken or fly samples from the same farm.

Our findings provide the first data regarding frequency of λ and M13 in man's immediate environment. As these phages naturally infect *E. coli*, their presence would be most evident in faecal samples. In this series of tests, both phages were easily found, but at relatively low frequencies. Our screening method identified wild-type phages with receptors (tail fibres) similar to λ or M13. However, it would not have detected M13-like and λ-like phages having regions of DNA homology and potential rescue ability, but different receptors. Thus heteroimmune lambdoid phages, such as 21, 82, 424 and 434 (ref. 13), would have been detected, but not ϕ80 (ref. 14) which has a different receptor.

The frequency of M13 has not previously been assayed. Dhillon *et al.*[9], assaying Hong Kong sewage, found 24 male-

Table 2 Frequency of phage isolation from faecal samples in different environments

Human samples	No. of samples tested for λ	% Samples with any phage	% Samples with λ-like phage	No. of samples tested for M13	% Samples with any phage	% Samples with M13
Hospital	50	44.0	0	33	60.6	9.1

Total	162	71.0	1.2	141	66.7	3.5
Non-human samples						
Flies	4	75.0	0	7	28.6	0
Chickens	4	75.0	0	5	60.0	0
Mammals*	9	100.0	0	17	64.7	5.9
Total	17	88.2	0	29	55.2	3.5

For assay of λ phage, faecal samples were plated onto MacConkey plates and incubated overnight at 37 °C. These samples were then replica-plated onto plates (Luria + 1 mM $MgSO_4$ + 0.2% maltose plates) containing newly inoculated lawns of logarithmically growing D0-28. As a positive control, a plate of *E. coli* U-7 (λ^+) was processed in the same manner as a test sample. After overnight incubation at 37 °C, the phages were collected by suspending the plate contents in 4 ml cold ϕ80 buffer. Cells were removed by pelleting in a clinical centrifuge. The resultant supernatants were diluted in ϕ80 buffer and assayed for phage using D0-28 and D0-29 indicator strains in soft agar overlays on nalidixic acid 30 $\mu g\ ml^{-1}$. For further testing, plaques were probed with microcapillary pipettes and resuspended in 0.5 ml ϕ80 buffer. For M13 phage assay, several loops of faecal bacteria from each sample MacConkey plate were used to inoculate 5-ml log phase cultures of B0-11 in TYE broth. This strain was used to enrich the male-specific phages. A culture of B0-11 inoculated with M13 was the positive control. Cultures were shaken overnight at 37 °C. Supernatants were obtained by sedimenting cells in a clinical centrifuge. Indicator cells for titration were grown to late logarithmic phase, sedimented and resuspended in an equal volume of 0.1 mM NaCl and shaken for 20 min. Cells were then pelleted and resuspended in 0.1 mM NaCl. Dilutions of supernatants in TE (10 mM Tris-HCl, pH 8.0 1 mM EDTA) buffer were plated with F^+ and F^- indicator cells in Trypticase medium soft agar overlays.

* Cattle, horses, cats, dogs, goats and pigs.

specific phages amongst the 77 phage isolates studied. Nine of the male-specific phages, 11.7% of the isolates, were considered to be single-stranded DNA phages by their 'turbid' plaque morphology and were inactivated by anti-AE_2 serum.

In a study of 500 strains of human *E. coli*, Jacob and Wollman[13] found only three isolates which were indistinguishable from λ by immunity, host range and antiserum neutralisation. Fourteen other temperate phages of unique immunity types shared some, but not all, characteristics with λ. Our findings appear similar to those of Jacob and Wollman, published in 1956.

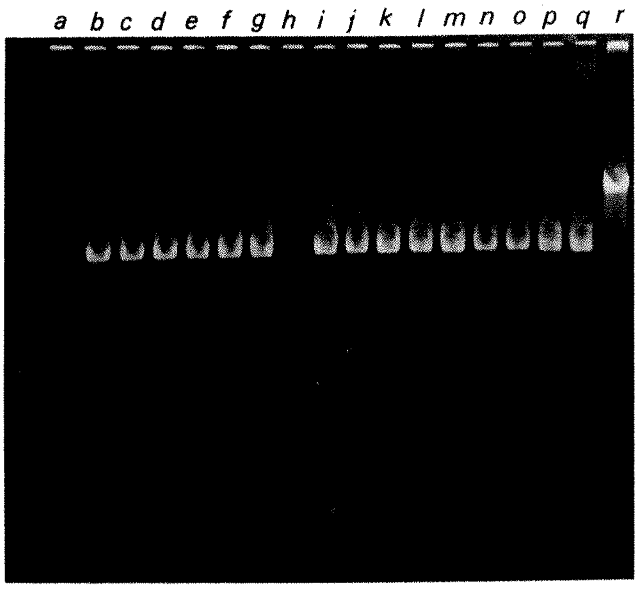

Fig. 1 Agarose gel (0.8%, 1.5 mm) electrophoresis in Tris-borate-EDTA buffer (*p*H 8.3) of supernatants from B0-11 cultures infected with plaque isolates. Aliquots of 30 μl of supernatants from phage-infected B0-11 cultures were added to 3 μl 2% SDS, 3 μl 0.25 M EDTA and 4 μl 0.1% BPB–50% glycerol and incubated at 65 °C for 10 min. Samples were then applied to the gel and analysed after electrophoresis for 3 h at 25 mA. Negative controls (*a*, *h*) were from two separate cultures of B0-11 cells alone. Positive controls (*f*, *l* and *q*) were native M13. Phage λ was applied to slot *r*. All other samples were phage isolates.

Our results can be used in assessing the potential for interaction of λ or M13 cloning vectors with wild-type phages in man's environment.

We thank T. Keller for technical assistance, J. Felton for helpful discussions, D. Ray for providing RF DNA, W. Wickner for antiserum to M13 coat protein, and G. Wilcox for native M13 phage. This study was supported by NIH contract N01A72529.

Host range of *Agrobacterium tumefaciens* is determined by the Ti plasmid

The plant pathogen *Agrobacterium tumefaciens* can induce crown gall tumours in a wide range of dicotyledonous plants. To be virulent an *Agrobacterium* strain must contain a tumour-inducing (Ti) plasmid[1,2]. Most Ti plasmids fall into one of two groups, based on whether they code for enzymes for octopine or nopaline utilisation[3,4]. Tumours induced by strains carrying octopine or nopaline type Tiplasmids generally synthesise octopine or nopaline respectively[3,4]. Normal plant tissues do not synthesise these unusual amino acid derivatives[5,6]. Chilton *et al.*[7] have analysed total DNA isolated from a cloned sterile tobacco crown gall callus and found sequences (T-DNA) complementary to ~5% of the Ti plasmid that are not found in normal tobacco callus. Thus, *Agrobacterium* can induce and maintain tumours by introducing genetic information stably into plant cells. It is evident that plasmid sequences have a central role in *Agrobacterium* virulence. Based on metabolic and physiological properties, most isolates of *A. tumefaciens* can be classified as either biotype 1 or biotype 2 organisms[8,9]. They have a broad host range, inducing tumours on most dicotyledonous plants. Recently, however, strains isolated in Greece and Russia from grapevine tumours have been shown to have a limited host range[10,11]. These organisms are also unique in that they do not fit into either of the previously described biotypes and have therefore been assigned to a new class, biotype 3 (refs 11, 12). We felt that these limited host range organisms could provide a system to study determinants of host range: if host range is determined solely by plasmid genes, the transfer of the Ti plasmid from a limited host range biotype 3 organism (assuming the biotype 3 organism had a Ti plasmid) to a biotype 1 organism that had been cured of its Ti plasmid, should yield a transformant of limited host range. The transformant should have a wide host range if this is a chromosomally borne trait. In this report we present data suggesting that the Ti plasmid has a major role in determining host range.

A. tumefaciens strains Ag57 and Ag63 isolated in Greece, and Ag158 and Ag162 isolated in Russia are biotype 3 organisms with a limited host range. Plasmids from these strains were isolated and subjected to electrophoresis through an agarose gel (Fig. 1). All of the isolates contained two large plasmids with molecular weights (MWs) of $\sim 140\times10^6$ and 130×10^6. Both Ag63 and Ag158 contained an additional plasmid with MWs of $\sim 65\times10^6$ and 72×10^6, respectively. Strain Ag162 contained two additional plasmids with MWs of about 55×10^6 and 28×10^6. Plasmids from the four strains were isolated and used to transform strain A136 as previously described[13]. This latter strain is a biotype 1 organism that has been cured of its virulence plasmid pTiC58 but retains a cryptic plasmid pATC58 (ref. 14, see Fig. 1). Transformants were selected on a minimal medium with octopine added (400 μg ml^{-1}) as the sole source of carbon and nitrogen. All four donor strains can catabolise octopine (M.F.T. and E.W.N., unpublished results; C.G.P., unpublished results) and we hoped that, as with biotype 1 organisms, this characteristic would be a

0028-0836/80/080794—03$01.00

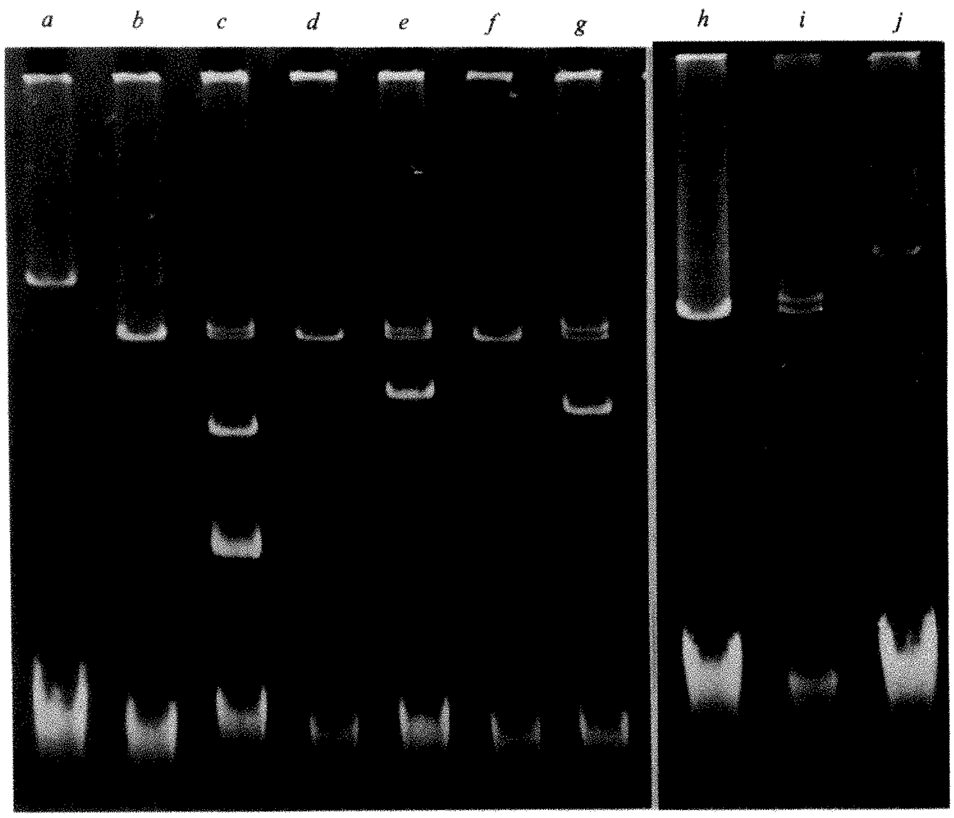

Fig. 1 Plasmids from *A. tumefaciens* strains with a limited host range and their respective transformants. Plasmid was isolated by a modified version of the Currier–Nester technique[24] as described by Casse *et al.*[14] Samples were subjected to electrophoresis through a 0.7% agarose gel as previously described[7] except that a vertical gel apparatus was used. Plasmid bands were visualised by staining with ethidium bromide (1 μg ml^{-1}) and illuminating with a Blak-Ray Transilluminator (UV Products). Samples are as follows: *a* and *j*, A136; *b*, Ag162Tr; *c*, Ag162; *d*, Ag158Tr; *e*, Ag158; *f*, Ag63Tr; *g*, Ag63; *h*, Ag57Tr; *i*, Ag57.

plasmid-borne trait. This proved to be true as octopine-utilising transformants were recovered. They were typical biotype 1 organisms in that they were 3-ketolactose positive and grew on the selective medium of Schroth *et al.*[15]. In each case the transformants (Tr) contained the 130 × 10^6 MW plasmid found in the parental strain (Fig. 1). When plasmids from the parents and transformants were digested with the restriction endonuclease *Sma*I and the products separated by electrophoresis on an agarose gel, restriction fragments of the plasmids from the transformants formed a subset of the restriction bands found in their respective parents (data not shown).

The *Bst*I restriction patterns of the plasmids from the transformants are presented in Fig. 2. The pattern of the pATC58 plasmid is not visible because its relative yield in the plasmid preparations is low (see Fig. 1). The patterns of the transformants are strikingly similar, suggesting that the plasmids are closely related. The banding patterns of the plasmids contained in Ag158Tr and Ag162Tr actually appear identical although their respective parents are obviously different (Fig. 1). Their pattern differs by only one band from that obtained with the plasmid from Ag63Tr. However, the restriction patterns of the plasmids in the transformants bear little resemblance to that of the pTi-B6-806 plasmid, the octopine Ti plasmid present in the biotype 1 strain A277. This is of interest because the restriction patterns of all octopine type Ti plasmids investigated to date have been virtually identical[16]. This is exemplified by the *Bst*I digestion patterns of two typical octopine plasmids, pTi-A6 and pTi-15955 (Fig. 2). These data suggest that octopine plasmids present in limited host range strains form a family of plasmids distinct from the wide host range octopine plasmids.

The host range of strains Ag57, Ag63, Ag158, Ag162 and their transformants is presented in Table 1. The virulence response of the transformant was virtually identical to the donor strain with all host plants tested. Significantly, when the donor strain gave an attenuated virulence response, as seen with Ag57 and Ag63 on sunflower and *Datura*, the transformants gave the same response. With tobacco, a slight difference in virulence between the limited host range donor strains and their transformants is suggested. Both Ag57 and Ag63 formed small,

Table 1 Virulence of *Agrobacterium* strains on various host plants

Bacterial strain*	Host plants						
	Grapevine *Vitis vinifera* c.v. Sultanina	Tomato, c.v. San Pietro	*Kalanchoë diagremontiana*	*Datura*	Sunflower	Tobacco (*Nicotiana tabacum* c.v. Turkish)	Tobacco (*N. glutinosa*)
Ag57	+	–	–	–/(+)	–/(+)	(+)	ND
Ag57Tr	+	–	–	–/(+)	–/(+)	–	ND
Ag63	+	–	–	–/(+)	–/(+)	(+)	ND
Ag63Tr	+	–	–	–/(+)	–/(+)	–†	ND
Ag158	+	–	ND	–	–	–	+
Ag158Tr	+	–	ND	–	ND	–	+
Ag162	+	–	ND	–	ND	–	+
Ag162Tr	+	–	ND	–	ND	–	+
A277	–	+	+	+	+	+	+
A136	–	–	–	–	–	–	–

The symbols used to describe the virulence response are; +, large active galls; (+), small galls that appear late compared with A277; –/(+), small galls that appear late and not at every inoculation site; –, no gall formation; ND, not determined.

* Strains Ag57, Ag63, Ag158, Ag162 and their transformants (Tr) are described in the text. The derivation of strains A136 and A277 have been described previously[2,16].

† This strain was avirulent on *Nicotiana tabacum* c.v. Turkish but gave very small, late appearing galls on *Nicotiana tabacum* c.v. xanthi.

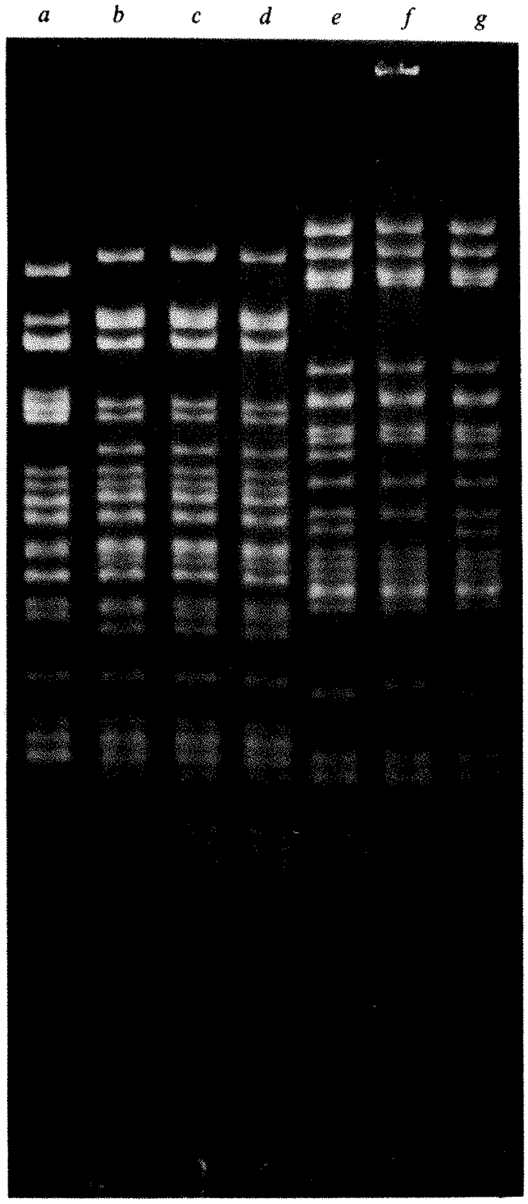

Fig. 2 *Bst*I cleavage patterns of isolated plasmids. Plasmid (0.5 μg) isolated by the Currier–Nester procedure[24] was digested with *Bst*I at 37 °C in a buffer consisting of 100 mM Tris-HCl (*p*H 7.6), 6 mm $MgCl_2$ and 100 mM NaCl. The products were separated by electrophoresis through a 0.7% agarose gel as previously described[7]. The restriction bands were visualised as in Fig. 1. Plasmid was isolated from the following strains: *a*, Ag57Tr; *b*, Ag63Tr; *c*, Ag158Tr; *d*, Ag162Tr; *e*, A277; *f*, A6; *g*, 15955.

slowly developing galls on *Nicotiana tabacum* c.v. Turkish, while the transformants formed no galls at all. Ag63Tr did form very small galls on *Nicotiana tabacum* c.v. xanthi. The data also show that although A277 has a wide host range, it is not virulent on grapevine. This inability to induce galls on grapevine must be a function of the Ti plasmid and not the chromosomal DNA as all the limited host range transformants formed large active galls on grapevine. It is clear from these data that the major determinant of host range for the strains tested is plasmid coded. The results obtained with tobacco suggest that chromosomal DNA, or possibly the other plasmids harboured by Ag57 and Ag63 might modulate host range to a limited extent.

How plasmid genes determine host range is not known. Apparently, effective binding of agrobacteria to plant cells is a prerequisite to tumour formation[17,18]. *A. tumefaciens* strains containing Ti plasmids bind more effectively to tobacco and carrot cells than do strains that do not harbour Ti plasmids[19,20]. These data suggest that it is the Ti plasmid that enables *Agrobacterium* to bind to plant cells. It is possible that the Ti plasmids from the limited and wide host range isolates allow *Agrobacterium* to bind to cells of different plant species. An analogous system for enteropathogenic *Escherichia coli* has been shown to exist. Plasmid sequences code for surface antigens that allow the bacteria to bind to animal cells; different antigens allow binding to cells from different animal species[21]. Without binding, *E. coli* strains that are able to produce enterotoxin are not pathogenic[22].

An additional ancillary conclusion that may be drawn from these data is that all octopine Ti plasmids do not form a homogeneous group as previously thought[16]. Current studies in our laboratories are aimed at determining the extent to which these and other limited host range octopine Ti plasmids differ from their wide host range counterparts.

Since submission of this letter we have transferred a wide host range Ti plasmid into strain Ag63. The transconjugant assumes the wide host range of the donor strain (V. Knauf and A. Montoya, unpublished observations). Our data on the importance of the plasmid in determining host range agree with the conclusions of Loper and Kado[23].

This research was supported by grant no. CA 13015 from the NCI. M.F.T. was a fellow in Cancer Research supported by fellowship no. DRG-209F from the Damon Runyon–Walter Winchell Cancer Fund. We thank Alice Montoya and Vic Knauf for assistance in the isolation of Ag158Tr and Ag162Tr.

In the News Feature 'Recombinant DNA: have recent experiments assessed all the risks?', *Nature* **282,** 773, 1979, column 3 lines 5–7 on page 773 should read ';intact recombinant λ or plasmid DNAs with single polyoma inserts gave variously 0, 6 and 9% tumorigenicity'. (Not 0.6 and 9%.)

BOOK REVIEWS

Other men's minds

Kevin Connolly

The Making of Mind: A Personal Account of Soviet Psychology. By A.R. Luria. Edited by Michael Cole and Sheila Cole. Pp.234. (Harvard University Press: Cambridge, Massachusetts, and London, 1979.) $15; £9.

"PEOPLE come and go, but the creative sources of great historial events and the important ideas and deeds remain." This sentiment, expressed in the penultimate sentence of Alexander Romanovich Luria's short autobiography gives the key to the book. It is one of that small genre of intellectual autobiographies; it is fascinating because of the man and his work, and important because it spans almost the whole of Soviet psychology as it emerged from the deep and frowsty conservatism of tsarist Russia after the October revolution.

Luria was born in Kazan in 1902, into the Russian intelligentsia class. Arguably he was the best known Russian psychologist of his day, a prolific writer and an inveterate traveller. The cataclysmic changes of 1917 had a profound effect upon him: "The revolution freed us, especially the younger generation, to discuss new ideas, new philosophies and social systems." Although not aware of the real causes of the revolution Luria, in company with other young people, threw himself into the new movement because of the opportunities which it presented. In the opening chapter the liberation offered by the revolution in those early years comes across as a passionate, almost spiritual, excitement which served to fuel his intellectual endeavours.

Amidst the turmoil in Kazan University in the immediately post-revolutionary years Luria became absorbed with the then rather formless set of topics in the social and biological sciences which we now think of as psychology. After graduating in 1921 he began to investigate the effects of physical work on mental activity. His early studies on the role of verbal instructions on reaction time led to an enduring interest in the regulatory role of speech. He was also much interested at this time in psychoanalysis and had founded the Kazan Psychoanalytic Association.

In 1923 he moved to the Institute of Psychology in Moscow. The new Director, Kornilov, was engaged in eliminating all traces of subjective psychology and replacing it with objective methods — his "reactology". While appreciating the need for objective methods Luria avoided the sterility of this simple mechanistic scheme, his interest in psychoanalysis probably bolstered him in this. He designed a technique which he called the "combined motor method" to study the influence of emotions on voluntary behaviours. This early work, which was never published in Russian, shows clearly one of his trademarks — the application of objective methods to real life psychological problems.

In 1924 he met L.S. Vygotsky whom he describes quite simply as a genius. For ten years he worked closely with Vygotsky whose ideas plainly had a profound and enduring effect upon him. Vygotsky's 'cultural psychology' owed much to Marx's methods of analysis and to the intellectual climate released in Russia after the revolution. Inspired by Vygotsky's ideas Luria, Vygotsky and a small group of students set themselves the task of reconstructing psychology with man in his proper historical and cultural context. These ideas led Luria in the early 1930s to make two expeditions to Uzbekistan in Central Asia. Here a traditional peasant society profoundly influenced by a conservative Islamic culture was in the process of being transformed by collectivisation, literacy campaigns and formal education. The purposes and methods, along with an outline of the findings obtained from the two expeditions are described. This brief account of the work on cultural differences in thinking done almost 50 years ago is one of the most interesting chapters in an absorbing book. It deals with work which is little known in the Soviet Union and even less in the west. Following these pioneering studies Luria turned to work on twins in an effort to disentangle nature and nurture as they shaped psychological processes. From the account provided one cannot help but be struck by the originality displayed in the work and by the way in which Vygotsky's theoretical framework is woven throughout it.

Luria was perhaps best known as one of the founding fathers of neuropsychology. In the late 1930s he completed his medical training in Moscow and set about becoming, as he puts it, "a practical neurologist". He made notable contributions to our understanding of the aphasias, once again informed by Vygotsky's theory. When Russia entered the second world war in 1941 he was commissioned to organise a hospital for patients suffering brain injuries. The development of his ideas and methods of rehabilitation, especially in relation to speech, are simply and vividly described. The link between the war work and subsequent studies on the relationship between brain and behaviour, especially in connection with language function, is explored.

The final chapter in Luria's little memoire has the beguiling title, "Romantic Science". He distinguishes between classical science which is essentially reductive in nature, and romantic science which is concerned with the broader canvas of the whole person. In psychology the distinction and the corresponding dilemma have often been formulated in terms of the nomothetic versus idiographic approaches. Luria's work takes from both of these but in a period when the nomothetic approach is in the ascendency in western psychology his clear statement about the sources of ideas and about the importance of preserving the manifold richness of the subject, which he illustrates by his detailed studies of a man with an amazing memory and another man whose mind was shattered by a severe brain injury, provides a timely caution to us all.

In their introduction the editors provide a valuable historical context to Luria's psychological work. The final chapter is a sensitive and insightful essay by the editors in which they seek to give a picture of Luria the man. This is plainly difficult but the vicissitudes of his life are outlined and provide some explanation for the striking changes in direction which his work took, changes often brought about by political necessity. The two great influences on the development of Luria's psychological work were the revolution, which opened it, and Vygotsky whose ideas provided a connecting framework which ran throughout it. The atmosphere of the intellectual life which is revealed shows Luria to be a man possessed of boundless energy and insatiable curiosity — a great man. The book is quite simply a gem. Because of its simplicity and directness it reveals that most fascinating of things, another man's mind at work. ☐

Kevin Connolly is Professor of Psychology at the University of Sheffield, UK.

David W. Hughes

Catalogue of the Universe. By Paul Murdin and David Allen, with photographs by David Malin. Pp.256. (Cambridge University Press: Cambridge, 1979.) £9.50.

cătálŏgue, n. a list or enumeration systematically arranged in alphabetical or other order, often with the addition of brief particulars.

ūn′ĭvêrse, n. The whole of created or existing things regarded collectively; all things, including the earth, the heavens, and all that is in them, considered as constituting a systematic whole.

ON reading these two dictionary entries the enormity of the task the authors had set themselves seemed overwhelming. Murdin, Allen and Malin have, however, assembled a much simplified catalogue of astronomical objects and planetary features. The book is a picture gallery of galaxies, stars, nebulae and planets, each photograph being accompanied, on average, by an equal area of prose. The balance is reasonable too: 26% galaxies, 36% stars and nebulae, and 38% planets.

In the preface the authors state that the photographs are the core of the book , and a "best-buy" policy has been adopted in selecting the ones for inclusion. They then bravely go on to say: "We hope that an astronomer browsing in the sections which lie outside his special field thinks that the best-buy choices are justified, even if he happens to disagree with us in the area he knows about." Well I did just that and obviously this makes me very worried. My field is the Solar System, especially the minor bodies in it — comets, asteroids, meteorites and meteoroids. The photographs in this section were poor — I'm sure I could have selected much better ones myself. Also having NASA slides in my collection of many of the Moon, Mercury and Mars photographs used in the book, underlined the fact that many of the reproductions in these sections are not of the best. However, as I wandered away from my field and browsed in other pastures I became more and more impressed. The Lagoon nebula looked sharper than I had ever seen it before, thanks to some of the special photographic techniques used for the illustrations. On the other hand, even here a common illustration like the Lund Observatory's composite photograph of the Milky Way has been so badly reproduced that much of the detail you know exists on the original is invisible, But I'm still worried about the author's admonition. May be if I meet an expert of that speciality in some distant pasture, wouldn't he be as disillusioned with his area as I was with mine? It's quite surprising isn't it how impressive certain books can be when they discuss things you haven't encountered before, only to become painfully weak when they turn to your own speciality.

The text also worries me. Common catalogues like stamp catalogues and horticultural catalogues at least tell you how big the stamps are, their perforation, the issue dates and print numbers; and when reading about the plants I expect to learn how tall and hardy they are or whether they like shade or sun. Common catalogues abound with quantitative details. Not so this one. Time and again I get the impression the reader is being talked down to. I want to know how rare, hot, massive, dense, luminous, old (etcetera, etcetera) these objects are, I'm not told often enough. If I've gone to the trouble of looking up "infrared radiation" in the glossary I want to be told more than that it is just heatwaves. Any author who writes that fireball trains are nearly as wide as the Full Moon sows seeds of doubt in my mind about his other prognostications.

The underlying, motivating, idea behind the book is extremely good. A catalogue of the objects of the Universe, well illustrated with a concise factual test would be most useful. Unfortunately with this book both the illustrations and the text let it down. Remove these and there is little to say other than that it has a pretty cover. ☐

Physical optics

P.W. Hawkes

Optical Image Formation and Processing. By M. Françon. Pp. 213. (Academic: New York, San Francisco and London, 1979.) $19.50; £12.80.

THE past twenty years have seen a number of major developments in optics, but for the newcomer, their relative novelty simply means that older textbooks will not cover them and that some of the newer ones, or new editions of the old, will treat them as difficult advanced topics or in brief, all-too-often obscure appendices. Professor Françon is too experienced a teacher of optics to fall into either of these traps. He has written a short introductory text on physical optics, in which such topics as partial coherence, transfer functions, holography, speckle interferometry, image processing, lasers and optical waveguides are treated alongside and in exactly the same tone of voice as, for example, Babinet's principle and the Michelson interferometer. Students encountering physical optics for the first time will find the style clear and the mathematics simple and easy to follow. Only in one case did I find the clarity deceptive, namely, the treatment of speckle; here, I feel that the newcomer will find himself following the discussion effortlessly but without the least idea of what speckle is all about.

In a book intended for beginners, the quality of the translation is particularly important. The translator, B.M. Jaffé, has produced a text that is smooth and lucid for the most part, though here and there a technical phrase has eluded him. The only one that matters is "pattern recognition", for which B.M. Jaffé writes "form recognition" (from *reconnaissance des formes*). From personal experience, I know how easy it is to be hypnotised into translating into perfectly grammatical but somewhat unnatural English and B.M. Jaffé is occasionally, though not often, guilty of this: "If one agrees to allow the frequency to vary . . . " (p 59), for example, and " . . . it will be necessary to remind the reader of the basic properties . . . " (p 98). Here and there, I felt he might have inserted (if the author agreed) a helpful phrase; thus again on p 98 it would have been useful to mention that fig. 8.1 is commonly known as the Hurter-Driffield or H-D curve and to put "log W" in the text. On p 190, he really ought to have noticed that, although "The first of the two relations (A.28) is often given the name of Parseval's theorem", this is in fact wrong and Parseval's theorem states something different, which is easily derived from the relation in question.

Nevertheless, these are only very minor blemishes in a book that first or second-year undergraduates, revising for exams, will find immensely helpful particularly if Academic Press produce a paperback that they can afford.

P.W. Hawkes is Maître de Recherches in the Laboratoire d'Optique Electronique du CNRS, Toulouse, France.

Semiconductor physics

Andrew K. Jonscher

Semiconductor Physics. By P. S. Kireev. Pp. 693 (MIR Publishers/Central Books: London, 1977.) £5.95.

THIS is an interesting novelty — a translation from Russian into English made and published in the USSR and offered at the bargain price, by any standards, of less than six pounds for nearly 700 pages in hardback. The first point to make is that the translation is remarkably good coming from a non-native English speaker and it would be churlish to quibble over small points of odd usage of English. That aspect is quite satisfactory.

The material is organised into the following chapters (with numbers of pages): introduction (31), band theory (138), electron and hole statistics (54), kinetic phenomena (135), scattering theory (92), recombination (36), contact phenomena including p-n junctions (35), optical and photo-electric phenomena (101), Appendix — group theory (61). The size of the chapters reflects fairly closely the Author's predilections and the strong points of his expertise, which evidently centre on theory; all treatment of 'concrete devices' is excluded. The quantum mechanical treatment of the band theory of solids is very thorough — certainly at postgraduate level — and includes the effects of magnetic fields, surfaces and point defects, but not strongly disordered solids. Simple examples of band structure calculations are also included. Carrier statistics is treated conventionally, includes a lot of detail and covers, in particular the quantisation in high magnetic fields.

The treatment of transport begins with Boltzmann's transport equation — going into considerable detail with tensor effective masses — and includes the treatment of galvanomagnetic phenomena, especially the Hall effect, heat conductivity and thermoelectric effects. It is noteworthy that frequent examples are given of experimental data to illustrate particular developments in the theory. The principal carrier scattering mechanisms are described in considerable details, and a rather unusual feature of the book is that lattice vibrations and specific heats are dealt with as a sub-section of this chapter. There is a brief treatment of high-field effects and deviation from Ohm's law, but this general subject is treated in a rather disappointingly sketchy manner and manages to give a confusing picture of the Poole, Stark, Poole-Frenkel and Zener effects. The important topic of transferred electron phenomena receives barely one page and one not very informative diagram: — one would have expected more after the very thorough preparation in earlier chapters. There is nothing about effective carrier temperatures in high fields and band-to-band avalanche multiplication, and saturated drift velocity is shown in a diagram but is not discussed in any detail.

After the very detailed treatment of the band theory, the presentation of the physical aspects of carrier recombination is decidedly perfunctory and the subject of minority carrier injection does not receive any significant amount of attention, either at the level of analysis or of a physical description of ambipolar flow and preservation of neutrality. The chapter devoted to contacts includes a very sketchy description of the p-n junction but the voltage-current characteristics of neither of these are derived. This is perhaps taking the avowed aim of excluding devices a little far, as the I-V characteristic may be considered to be both fundamental to the theory of semiconductors and highly illuminating physically of a range of transport phenomena.

By contrast with the above, optical and photoelectric phenomena are treated again quite thoroughly, especially free carrier absorption, cyclotron resonance, plasma reflection, intrinsic absorption in considerable detail, lattice absorption and impurity absorption. Likewise, photoconductivity, photovoltaic effects and photoelectromagnetic effects are given reasonably good coverage, with illustrations relating to experimental results.

There is an appendix on group theory which is useful for the beginner, although the precise logic of including this rather than any other supporting material is not obvious. A good feature of the book are the brief summaries at the end of each section which should be useful for revision and for rapid scan of the principal features.

Although carefully selected passages of this text would be suitable for an undergraduate course, the treatment is definitely postgraduate, and rather specialised at that. The book is literally packed solid with information — the typographical layout is very condensed, with 46 lines to a page of slightly smaller format than an equivalent Western text with 38 — 39 lines. Similarly, mathematical expressions, of which there is a great deal, are tightly packed in the text and most of the diagrams are very small by our standards. Thus, although the reading process may be more tiring, the book contains a good 20% more information per page than its equivalent here.

The quality of paper is not high — especially as the book is liable to get thumbed readily in extensive usage. A very serious defect — not untypical of Soviet books — is the omission of an index, expecially in a text that is more likely to serve as a reference source rather than as a regular reading text.

Altogether, a very mixed impression. A first-class bargain in terms of the sheer quantity of information per pound sterling, good coverage of theoretical aspects such as band theory, transport and optical phenomena, but quality of treatment falling off rapidly in other areas. In those areas in which it is strong it should form a good reference source, although I would dread having either to teach or to read a course of that level of detail. Perhaps the publishers may be able gradually to take into account the different standards of presentation normally expected in the West, thus further increasing the attractiveness of the product, even if that meant raising the price by as much as 50% — it would still remain a bargain! ☐

Yeast identification

B.H. Kirsop

A Guide to Identifying and Classifying Yeasts. By J.A. Barnett, R.W. Payne and D. Yarrow. Pp. 315. (Cambridge University Press: Cambridge, 1979.) £32.50.

THE yeasts are a heterogenous and important group of organisms which are widely distributed, commonly isolated and often in need of identification. This *Guide* has been written to help overcome difficulties in identification and is intended to be used in conjunction with the standard work *(The Yeasts,* edited by Lodder, North Holland, 1970). Those experienced in yeast identification will meet little difficulty and so the present work must be judged by the extent to which it helps the inexperienced.

The *Guide* provides condensed but useful descriptions of methodology and of the principles of clasification. It lists the salient properties of each genus and provides a particularly valuable tabulation of the major physiological and morphological attributes characteristic of each species. Identification is based on keys, a general one being provided for yeasts as a whole; there are also special keys to smaller groups, such as those likely to occur in particular habitats or those possessing specific morphological or physiological attributes. Testing with unnamed yeast showed that the keys are easy to use and readily yield names. In a significant proportion of cases this name differed from that deemed appropriate when all the properties of the organism were considered; the discrepancies arose either because an organism was atypical for its group in a characteristic used in the key — all microbiologists know well the atypical organism — or because of difficulty in interpreting test results. The authors recognise the problem, for they provide a useful summary of the features which distinguish each species from all, or all but a named few, other species; and this helps the inexperienced to detect errors.

In spite of this drawback, the *Guide* provides much useful information which is particularly valuable for the expert, for it brings together in one place much information published since the 1970 edition of *The Yeasts*. Since then many new species have been described and massive reorganisations of taxonomy have been recommended, accepted by the authors and incorporated into the keys. Although this makes it difficult to use the *Guide* in conjunction with the 1970 edition, as recommended by the authors, the ready accessibility of this information is nevertheless most welcome. One is tempted to wish that the authors had produced a still more substantial monograph which would have been of great value to the beginner and to the expert alike. □

Dealing with information in the nervous system

H. B. Barlow

Information Transmission in the Nervous System. By A. M. Uttley. Pp. 111. (Academic: London and New York, 1979.) £7.50; $15.50.

It is obvious that Pavlov's dogs, who salivated when a bell sounded, had in some way formed an assessment of the conditional probability of food, given the sound of a bell; because the dogs' past history had been controlled so that this probability was high, they salivated on the sound of a bell, without waiting for the food. In this sense, the nervous system must be able to compute conditional probabilities, and this is the starting point for the work, stretching back over 30 years, that Albert Uttley summarises in this book.

I think he is right in giving central importance to the question how conditional probabilities are assessed in the nervous system, and I also like another feature of his approach. Given its central importance, he says, let us explore the hypothesis that modifiable synapses in the nervous system are commonly arranged in such a way that the modified synapse stores a conditional probability. The book is a development of this theme, and centres on the "informon", an element for which a stored variable, Y_i, representing the effectiveness of a synapse, is given by

$$Y_i = -k\log(P(X_i \text{ and } Y)/(P(X_i) \times P(Y)))$$

where k is a positive constant, and $_i$ and Y are two binary signals, the X's usually representing inputs and Y an output. Y_i is thus the negative of Shannon's Mutual Information Function for X_i and Y. Before going into further details two warning are required.

First, the title might mislead the unwary reader. It is not a general treatise on how information, in the general sense, is transmitted in the nervous system. Rather, the title was chosen, I suspect, to emphasise that "informons" adjust themselves in accordance with "information" in the specialised Shannon sense, rather than just messages; they store the conditional probabilities that enable them to deal effectively with information.

The second warning is that, although I am sympathetic to the author's general purpose and train of though, I did not find the book easy to read and follow. The author has perhaps lived with the ideas so long that he no longer has the perspective necessary in order to explain them effectively to newcomers.

The book contains eleven short chapters. The first four explain the concepts and illustrate how a theoretical "informon" might be realised by a nerve cell with modifiable and unmodifiable synaptic imputs. The next two chapters match the conceptual informon's behaviour against that of granule cells in the hippococampus, as shown by the work of Bliss and Lomo in rabbit and Douglas and Goddard in rat. He then deals with classical conditioning, the use of informons for pattern recognition, the interpretation of plasticity in the visual cortex, and the extension of the ideas to operant conditioning.

The book is a valiant and rather isolated effort in an original direction. It should be read by those who seek an explanation for quite complex psychological facts in elementary properties of synapses and nerve cells, and it thus forms a contrast with explanations for those same facts in terms of "programs" that could be realised by any kind of computing machinery. Conditional probabilities and Shannon's Information are quantities that form conceptual bridges between the two approaches, and the most valuable feature of Uttley's work may be to show how much can be achieved directly by neural hardware adapted to computing these quantities □

Objectives of agricultural policy

R. F. Lord

Government and Agriculture: A Spatial Perspective. By I. Bowler. Pp.127. (Longman: Harlow, 1979.) Paperback £4.50.

Dr Bowler is one of a growing band of geographers concerned not only to describe, but also to hypothesise. In this book he takes the view that "a spatial perspective can provide additional insights into the government — agriculture relationship". That he only partially succeeds in his task is due largely to the fact that objectives of agricultural policy rarely contain a specifically spatial dimension and that even where they do, statistically acceptable data are seldom available on a spatial basis in order to measure achievement.

The first part of the book drawing on experience in a number of developed countries, with a wealth (surfeit?) of references, considers how agricultural policy has been influenced by the changing nature of the "agricultural problem" and concludes that for the most part there has been a failure to achieve the policy goals so optimistically set by governments.

The second part of the book relates solely to the development of UK agricultural policy in the post-war period up to 1973. Only in the last two chapters (6 and 7) is attention devoted to the spatial aspects of the problem (which considering the title of the book is surprising). Generally the ineffectiveness of measures in a spatial sense is demonstrated. However, Dr Bowler's concern for the spatial dimension is justified in his concluding paragraph where he refers to the need for more research of this type if problems of formulating adequate regional policies in the EEC are to be overcome. □

28 February 1980

Smoking and health: time for a legal commitment

THE extent to which Mrs Thatcher's government is prepared to discourage smoking will become clear within the next few weeks. For by the end of March the UK government and the tobacco industry are due to have renewed their voluntary agreement on advertising. And on 26 March the tax on tobacco can be adjusted in the budget. It will be a great pity if either opportunity to discourage smoking is wasted.

Given that one in ten UK deaths can be directly attributed to smoking and that one smoker in four dies10-15 years prematurely, there can be no question about whether smoking should be discouraged. The question is:how? There are three traditional answers. The first is to increase the price of tobacco, the second is to reduce advertising and the third is to educate the public on the dangers of smoking.

On the issue of price, the UK National Consumer Council has recently produced figures which show that, in real terms, the retail price of cigarettes in 1978 was only 76% of what it had been 10 years before. Given that price increases are commonly held to be the most effective and lasting way of reducing cigarette consumption, there is a very strong case at least for restoring the relative cost of smoking by increasing the tax on tobacco in the next budget.

The advertising of cigarettes is already limited by a voluntary agreement that was negotiated between government and industry in 1977. This stopped the advertising of cigarettes on television or during cinema performances to which the young were admitted. Other forms of advertising were not stopped but controls were placed on the image of smoking portrayed. It is difficult to prove that the level of advertising has any effect on the consumption of cigarettes rather than, as the industry argues, just on the choice of brands — but it seems prudent to assume it does. The immediate aim of the government should therefore be to limit advertising still further and ultimately to the point of sale. Furthermore, at the end of the year, the government should make the most of its opportunity to renegotiate the voluntary agreement on sponsorship of sport by the tobacco industry, a promotional exercise to the tune of an annual £10 million that has done much to associate smoking with health and youth in a way that advertising has not been allowed to do since 1977.

As for anti-smoking campaigns, on which the government spends something like one hundredth of the industry's budget for promotion, the cheapest and most direct way of publicising the hazards of smoking is on the cigarette packages themselves. There is much scope for expanding and varying the present trite warning that "cigarettes can seriously damage your health".

Any attempt to reduce the consumption of cigarettes, however,needs to be complemented by efforts to reduce the risks to those who continue to smoke regularly. This currently includes 45% of male and 37% of female adults in the UK; the prevalence is falling but only markedly so in the higher socio-economic classes — for example among professional males the prevalence of smoking has fallen from 33% in 1972 to 25% now, whereas 60% of unskilled male manual workers still smoke compared with 64% in 1972.

One erstwhile promising approach to reducing the health hazards of smoking has clearly come to nothing. The idea was to replace some of the tobacco in cigarettes by a substitute that was, at best, harmless. A great deal of money was invested by the tobacco industry in the development of two tobacco substitutes. Early in 1977 the first report of the Independent Scientific Committee on Smoking and Health (the Hunter Committee) concluded that neither substitute was likely to be more harmful to health than tobacco alone and cigarettes containing them were launched in the UK later that year. But, as the recently published second report of the Hunter Committee says, sales of these cigarettes only briefly accounted for more than 2% of total sales.

Much greater success has met the introduction of low-tar brands of cigarettes and their acceptance by young smokers is probably the major cause of the declining trend in lung cancer deaths in UK males of less than 65 years of age. While welcoming the declining tar yields and recommending further substantial reductions, the second report of the Hunter Committee is less than forceful in its demands. It is left to the minority report of Dr J. D. Ball to point out that the average tar yield per cigarette sold in the UK has fallen very little since dropping 40% between 1965 and 1973. What is more disturbing is that the committee so strongly emphasises that reductions in tar yield will be limited by consumer acceptability of low-tar cigarettes. That appears to be a viewpoint that is more concerned with protecting the industry than it is with testing the limits of acceptability as a matter of urgency. Meanwhile the tobacco industry is apparently eager to spend £1 million on epidemiological studies of those who switch to low tar cigarettes rather than to admit that there is a case for reducing the tar levels now.

The attack on smoking can be pursued down a variety of paths, each one of which deserves to be explored vigorously. Voluntary agreements between government and industry are to be welcomed if they work — but there is considerable evidence that the tobacco industry has been less than scrupulous in honouring its commitments. That being so, the government should not be afraid to replace voluntary restrictions with legal ones if the tobacco industry is reluctant to agree to much stiffer controls on its distasteful business. □

Environmentalists warn of continued threats to water supplies

DESPITE progress in reducing the more obvious sources of water pollution, US regulators are beginning to feel that problems in maintaining a clean and healthy water supply will play as controversial a role on the political agenda of the 1980s as the energy crises has done during the 1970s.

The latest warning of difficulties still to be faced comes from the Council on Environmental Quality, the watchdog committee established by President Nixon in 1970. In its latest annual report, published in Washington last week, the council says that the general standard of air quality has increased substantially over the past decade. In contrast progress in cleaning up water supplies has been far less impressive.

In particular, the council says that ground-water contamination from various activities, such as the use of pesticides in agriculture or the improper disposal of toxic wastes, is becoming a major problem for drinking-water supplies in parts of the country.

It draws attention to the impact of "acid rain" on wildlife and water quality: and looking ahead, picks out the problems of carcinogens in drinking water, supplies to "water-starved areas", and ageing distribution systems as three "basic and difficult problems" that the nation will have to face in the next few years.

Coming to grips with such problems may require new legislation and substantial resources: updating distribution systems, for example, could cost $50 billion to $100 billion nationwide to prevent large-scale disruption of supplies.

Yet left unsaid by the CEQ is that the Environmental Protection Agency is already struggling to carry out existing responsibilities which it has been given by Congress and in many cases the agency is meeting strong opposition from water utilities, who claim that new regulations to control toxic substances in water, for example, are over-restrictive and unnecessarily expensive.

Not that the picture is all gloom. The CEQ's report points out that there has been considerable success in controlling efficient emissions from factories and other identifiable industrial activities since the Clean Water Act was passed by Congress in 1973.

But statistics illustrate the severity of the problems that remain. Thus the report says that as many as two-thirds of the nation's lakes may have serious pollution problems and that an estimated 80% of the 37,700 lakes in urban areas in the US are "significantly degraded".

This pollution is inevitably taking its toll of wild-life. In many lakes and rivers, toxic chemical contaminants such as PCBs have made fish inedible. Acid rain has made many lakes, particularly in the north-eastern United States, lethal to fish and other aquatic life and four million acres of commercial shell-fish waters have been closed.

The extent of the continuing pollution problem is also demonstrated by the fact that there has been "little or no overall change in the levels of five major water pollution indicators — fecal coliform bacteria, dissolved oxygen, total phosphorus content, total mercury, and total lead — over the four years 1975 to 1978, the CEQ reports.

Industry, in some ways a comparatively easy target for the EPA, has responded relatively well to control legislation. Although some industries, in particular the steel industry, have resisted stringent effluent restrictions, 90% of industrial discharges now meet "best practicable technology" standards laid down in 1977.

Municipalities responsible for water treatment have been more of a problem. Although federal funds have been made available for sewage treatment facilities since 1973, for example, many urban areas have been reluctant to take them up. Elsewhere construction projects have been plagued by cost-overruns and profiteering.

As a result, municipal sewage wastes are still "years away from being totally controlled" says the CEQ.

Furthermore both industry and water utilities are responding warily to what one EPA official refers to as the "second generation of water clean-up" shifting attention from more well-known and obvious pollutants to the long term effects of relatively low levels of toxic substances.

The agency, for example, is already experiencing considerable difficulty in carrying out some of the requirements of the Safe Drinking Water Act of 1974, introduced after environmentalists found abnormally high cancer rates among residents of Louisiana who used water supplies from the Mississippi river.

Further difficulties are likely to face the EPA as it moves to implement industry-by-industry guidelines for the regulation of 129 top priority pollutants — mainly heavy metals and substances known or suspected to be carcinogenic — agreed after pressure from groups such as the Environmental Defense Fund to follow through on the agency's congressional mandate.

Then there is the growing problem of acid rain. This is caused when emission from automobiles or power-plants combines with water in the atmosphere.

Here the CEQ points out that in the eastern half of the US the acidity of rainfall appears to have increased about 50-fold during the past 25 years. In addition to eliminating fish from lakes in the north-eastern US and Canada, acid rain, it says, "is also suspected of contributing to the leaching of toxic compounds into drinking water, especially surface water supplies".

All these problems are likely to mean increased responsibilities for the EPA. And the CEQ indicates that it is well aware of the difficulties faced, for example, in shifting the focus of control from point to "non-point" sources of pollution, such as run-off from construction sites, agricultural land or chemical dumps.

On top of all the other problems, the EPA is now faced with a bill introduced into the House of Representatives by Representative Phill Gramm of Texas, which would seriously limit its ability to enforce new quality controls: few believe the bill would pass solely on its technical merits but it could ride on the back of popular anti-regulatory sentiment and win a surprise victory. **David Dickson**

Panel to assess formaldehyde health effects

THE US Consumer Product Safety Commission announced last week that it is to set up a panel to help assess the human implications of research findings that exposure to formaldehyde can cause cancer in laboratory rats. The panel will be established in conjuction with the National Toxicology Programme, and will be assembled from various federal health and safety agencies and scientific organisations.

Last October, scientists from the Chemical Industry Institute of Toxicology and the Formaldehyde Institute reported that three laboratory rats of several hundred exposed to formaldehyde gas had developed prominent nasal cancers which were identified as squamos cell carcinoma.

Health scientists from CPSC and other regulatory agencies were told last month that such cancers were now evident in 37 of the rats in the study, which is three-quarters of the way through its two-year duration. In a random sample of rats selected for sacrifice and pathological examination after exposure at the dose level of 15 parts per million, 20% showed evidence of squamous cell carcinoma. □

Scientists protest at exclusion of Russians from conferences

US scientists reacted with anger and embarrassment last week to the decision by federal authorities to bar Soviet-bloc delegates from two scientific conferences, one on computer technology the other a joint conference on laser engineering and inertial confinement fusion.

The decision appeared to contradict earlier statements by the administration that, although cutting off high level exchanges with the USSR following the invasion of Afghanistan and the exile of Andrei Sakharov, it intended to maintain lower-level scientific links.

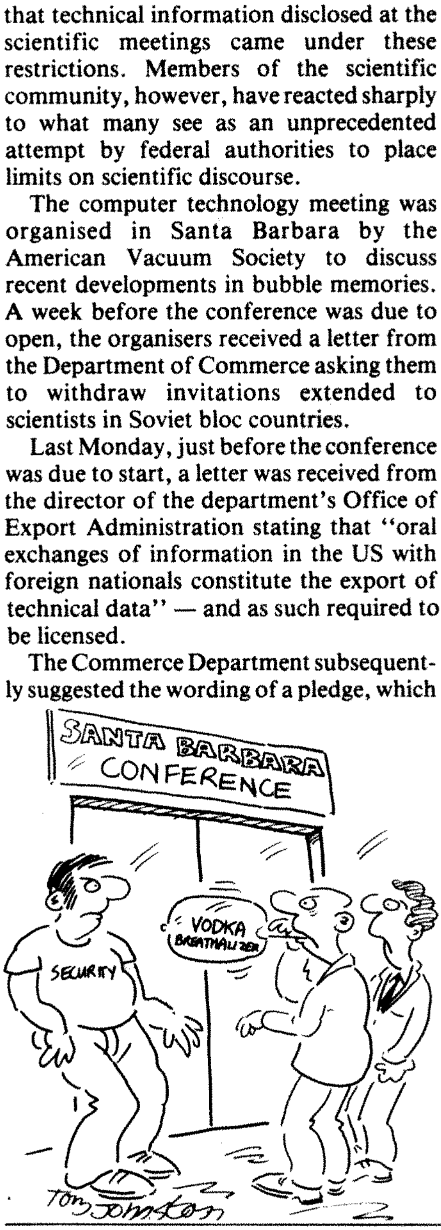
But administration officials point out that the decision to exclude Soviet participation was taken to restrict high technology exports.

Commerce and State Department officials, acting apparently without prior consultation with the White House, argued that technical information disclosed at the scientific meetings came under these restrictions. Members of the scientific community, however, have reacted sharply to what many see as an unprecedented attempt by federal authorities to place limits on scientific discourse.

The computer technology meeting was organised in Santa Barbara by the American Vacuum Society to discuss recent developments in bubble memories. A week before the conference was due to open, the organisers received a letter from the Department of Commerce asking them to withdraw invitations extended to scientists in Soviet bloc countries.

Last Monday, just before the conference was due to start, a letter was received from the director of the department's Office of Export Administration stating that "oral exchanges of information in the US with foreign nationals constitute the export of technical data" — and as such required to be licensed.

The Commerce Department subsequently suggested the wording of a pledge, which all foreigners attending the conference were obliged to sign, stating that they would not reveal any information obtained during the meeting to citizens of the Soviet bloc or other communist countries — including China.



(Three Chinese scientists who had arrived in Santa Barbara for the meeting were also excluded but were admitted on the second day partly, it is believed, as a result of the intervention of the Office of Science and Technology Policy which has been actively engaged in establishing US-Chinese links in science and technology).

The meetings on laser engineering and inertial confinement fusion are being held this week in San Diego, and are jointly organised by the Institute of Electrical and Electronic Engineers and the Optical Society of America.

A Russian post-doctoral student currently studying at the University of Texas, who had had a paper accepted for presentation at the meeting, was subsequently refused permission by the State Department to travel to San Diego to deliver it. On enquiring about this decision, Dr Jarus Quinn, President of the Optical Society, says the State Department told him that several Russian scientists had applied for visas to attend the conference, but that these would be refused.

Commerce Department officials insist that they are merely carrying out the intent of legislation restricting Soviet access to US technology and that the pledges required of participants in the Santa Barbara meeting were necessary to avoid violating technology transfer laws. But the scientists see it differently.

Dr J. Allen Bromley, professor of physics at Yale University and a past chairman of the International Union of Pure and Applied Physics, said that the US action might infringe a position statement issued by the International Committee of Scientific Unions on the behaviour expected of a country hosting international scientific conferences. "If allowed to stand it could damage in a very serious way US participation in international science," he said.

Mr William Carey, Executive Officer in the American Association for the Advancement of Science, commented that the government's actions reflected a "very summary procedure", to interfere so awkwardly in a non-governmental scientific conference.

"It is one situation where the government is managing exchanges carried out under agreements made with another government. It is quite another to interpret a statute and invoke it with no precedent to limit scientific discourse that has been called under private auspices", he said. ☐

Carter terminates work on nuclear waste disposal project

PRESIDENT Carter has announced the cancellation of the Waste Isolation Pilot Project (WIPP), planned to study the result of depositing high-level nuclear wastes in salt mines near Carlsbad, New Mexico. He argued that to proceed would be inconsistent with the administration's strategy of comparing sites with differing geological characteristics before agreeing to the construction of test disposal facilities.

The President's decision was announced as part of a comprehensive radioactive waste management programme, in which decisions to initiate construction of waste disposal plants are to be put off until further knowledge has been obtained on the behaviour of mined geological repositories capable of accepting waste from both reprocessed and unreprocessed commercial spent fuel.

Final decisions on many steps which need to be taken "should be preceded by a full environmental review under the National Environmental Policy Act", the President said. He added that the Department of Energy had already mounted an expanded and diversified programme of geological investigation that recognised the importance of the interaction among geological setting, repository host rock, waste form and other engineered barriers on a site-specific basis.

"Immediate attention will focus on research and development, and on locating and characterising a number of potential repository sites in a variety of different geological environments with diverse rock types", the President said. "When four or five sites have been evaluated and found potentially suitable, one or more will be selected for further development as a licensed full scale repository."

President Carter's decision to terminate the WIPP project, long opposed by environmentalist groups in New Mexico, was also partly based on his desire that all repositories should be licensed. The involvement of civilian licensing bodies had been opposed by defense officials, who would also have used the facility for storing high-level wastes.

As part of his waste storage programme, the President also announced the establishment of a state planning council of elected state, local and tribal officials and heads of cabinet departments and other federal agencies. "The basis of the relationship between states and the federal government in the siting of high level waste repositories will be the principle of consultation and concurrence," the President said. ☐

United Kingdom

PWRs unlikely to be safe, says metallurgist

CRACKS in the pressure vesels of pressurised water nuclear reactors would be very difficult to detect before they led to catastrophic failure, Sir Alan Cottrell, ex head of the University of Cambridge Department of Metallurgy, told the House of Commons Select Committee on Energy last week. Britain should therefore reverse its decision to build a series of PWRs, and adopt the advanced gas-cooled reactor instead, he argued.

Sir Alan appeared undismayed by the delays in the UK's AGR programme. "They are constructional" he told *Nature*. "The Hinkley Point AGR has performed extremely well." (Hinckley Point, the only AGR in operation, achieved 80% of its design capability in 1979, with an output of over 1000 MW, the Central Electricity Generating Board said this week.)

Sir Alan's first objection to the PWR was that it uses water rather than carbon dioxide as a coolant. "There is a natural safety in CO_2 which H_2O lacks" he says in his written evidence. This is that CO_2 remains gaseous under all reactor conditions, whereas H_2O can exist in two phases — liquid and gaseous — "with very different densities, coolant properties, heat contents, and pressure-volume-temperature relationships".

This leads to two safety disadvantages. First, a PWR must be operated at 150 atmospheres pressure to keep the H_2O liquid at its operating temperature of 320°C; and second "the problems of controlling an irregularity in the operation of a reactor are exacerbated if there is a risk of the coolant suddenly changing its physical state and losing its coolant properties".

The problems which faced the operators at Three Mile Island — "the speed of changes in the reactor, the false indications of the physical state of the coolant, the rapid overheating of the fuel due to the disappearance of the water" — would not have arisen in an AGR "with its lower power density, large mass of heat-absorbing graphite and invariably gaseous CO_2 coolant".

The second objection Sir Alan raised was that it would not be possible to detect a crack in the pressure vessel by the leaking of radioactive material until it was too late.

"To hold the water pressure, the walls of a PWR vessel and circuit have to be thick, up to 14 ins in places, and are made of a fairly hard, strong steel. The thickness and hardness deny the possibility of 'leak before break'. For under these conditions, the critical crack size at which a sharp crack will spread rapidly and uncontrollably is expected normally to be about four inches but could be as little as one inch under fault conditions. It follows that, if a wall becomes perforated by a growing crack, while under operational pressure, the crack is already unstoppable and will spread to form a major break within a millisecond."

"The security of the reactor thus depends on the avoidance of critically-sized cracks or similar defects in the steel."

Dr Walter Marshall, deputy chairman of the United Kingdom Atomic Energy Authority, had chaired a study of pressure vessel integrity and concluded, according to Sir Alan, that "the assurance of initial safety depends on meeting a number of exacting conditions about standards in workmanship, care in operational control, and rigour in inspection". These conditions, said Sir Alan, "call for considerable human abilities". It was a matter for general judgement "whether this degree of reliance on human abilities provides an adequately sound basis for the safety of a nuclear reactor".

Another worry, said Sir Alan, concerned the possible growth of small cracks, harmless at first, due to metal fatigue and corrosion. If these were discovered (as they have been in some French PWRs) there would remain the problem of repair in reactor conditions.

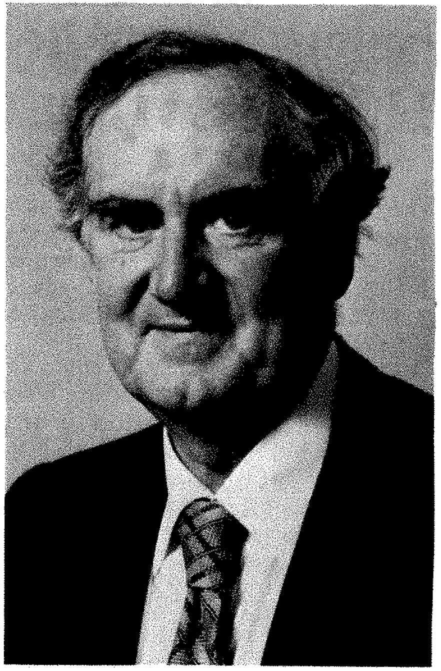
"The task of developing new equipment to grind out and soundly weld up cracked regions in radioactive steel, remotely by automatic methods, is a formidable one. But if such cracks were allowed to remain and were then to grow large, a government would be faced with a most difficult decision: either to take the chance of running the reactor . . . or to shut-down the reactor at a fraction of its planned economic life."

"The long-term value of PWRs may thus depend on the development of a new technology for the remote repairing of thick radioactive steel."

Dr Walter Marshall said on Monday that he accepted the technical basis of Sir Alan's arguments as "correct and completely valid". But "by selecting facts you can give the wrong impression".

For example, on the positive side of water as a coolant is that it is also a moderator — so loss of coolant will also stop the nuclear reaction.

On the "considerable human abilities" required of pressure vessel manufacturers, Dr Marshall said "there are firms abroad that can attain the necessary standards. For example, we could get steel from Japan; and among others Framatome in France and GHH in Dusseldorf could fabricate the vessels."



Sir Alan Cottrell: doubts about pressure vessel integrity

Was it wise to rely on Framatome, which has discovered cracks in pressure vessels it has built for French reactors? "Well, their big advantage is that they are busy. They may have made one boo-boo but they've learned from it."

"The technology is moving to larger and larger forgings" said Marshall "which you weld together. So ultimately it's the steel manufacturer who matters most. In England River Don in Sheffield could do it."

Dr Marshall does not want to be "sloppy" about inspection. "I want to be able to lay my hand on my heart and say, that one's OK." He would like to have "the full resources" of the UKAEA behind him; the authority itself should be the inspectorate.

If cracks are found, they must be repaired *in situ*, a task which will not be impossible, thinks Marshall. "You would grind out the crack, and not bother to replace the cladding. The water would just get a little rusty." Six specially protected divers successfully replaced the complete reactor support structure under water inside the 'Stada' German reactor in 1973, said Marshall.

Monitoring known cracks, like Framatome's, would not be difficult, but "the most sophisticated, the fundamental question is whether your initial inspection misses any cracks. I couldn't emphasise the importance of the initial inspection too much" said Marshall.

Commenting on Dr Marshall's remarks Dr Cottrell told *Nature* that he feels Dr Marshall has underestimated the repair problems but "we agree on most technical questions; we differ on where we go from there. I take a less cheerful view on whether this rigorous inspection can be achieved. In my view, it's simply asking too much."

Hamburg Scientific Forum

No agreement yet over minimising bureaucratic barriers to exchange

INTERNATIONAL scientific exchange must not merely take place; it must be seen publicly to take place. That is how one delegate to the Hamburg Scientific Forum has explained its purpose. The Forum has brought together leading scientists from Europe and North America for two weeks in the service of what has been referred to as the CSCE process, i.e. the implementation of the Helsinki Accords on peace and security in Europe.

The Soviet invasion of Afghanistan and the internal exiling of Academician Andrei Sakharov to Gor'kii mean that the forum is convening among what Dr Armand Boever of Luxembourg calls the "menacing strom cloud of the last few weeks". Inevitably the opening statements by the participating countries delivered last week, put considerable emphasis on the concepts of academic freedom and the responsibility of scientists towards society.

Strong statements on the human rights issue, sometimes citing the Soviet Union by name, sometimes, as did Dr Andre Lwoff (France), referring to breaches of the Helsinki accords in "a certain country", drew an emphatic refutal from the leader of the Soviet delegation, Dr Nikolai Blokhin. "The basic objection is that we observe our laws", he protested, speaking under the right to reply. "There have been no violations of Soviet law in the Sakharov affair. And Gor'kii is not exile. I myself was born there."

This undertone of confrontation which ran through the entire two and a half days of opening statements, focused attention on the fact that the forum was not, properly speaking, a scientific meeting. When, finally, the preliminary statements were over, and the meeting divided up into working groups on pre-selected topics (alternative energy sources, food production, cardiovascular, tumour and virus diseases, human environment and urban development), the scientists in the various delegations, irrespective of their countries' political system, seemed only too anxious to come to grips with the basic problem of promoting international scientific exchanges.

The majority of western delegates felt that if the forum were to make any real contribution to international exchange — as opposed to simply demonstrating scientific cooperation in the service of detente — it could best do so by endeavouring to eliminate or at least minimise the bureaucratic barriers to such exchange.

Since almost all the 35 delegations contained a sprinkling of bureaucrats, who sat in on the various working groups, the forum seemed an ideal opportunity for the scientists to make known their grievances against official frustration and obfuscation. This, however, various Soviet delegates were unwilling to allow. Repeated attempts to raise, in the closed working sessions, questions of visas, the cancellation of visits at the last moment for no clear reason, the substitution at conferences of some scientific nonentity for the speaker originally invited, and all the other difficulties and disappointments familiar to the would-be hosts of Soviet scientists, were quashed by the various Soviet representatives. "We are not here to discuss such matters" was their attitude — in which case, one might well ask with Dr Th. P. Tassios (Greece) what unique purpose the forum could serve.

Dr Tassios suggested that a permanent steering committee should be established to "define and shape" scientific "goals" and to deal with the whole problem of the ethics of science. To judge from the opening statements and the general tone of the Forum so far, this is a minority view. Most delegates, at least from outside the socialist bloc, seem to agree with Lord Todd (UK) that whatever the forms of future cooperation to be agreed by the Forum, more organisations to take scientists away from the bench and into the conference jet-set are not needed.

Vera Rich

United Kingdom

Split over admissible evidence at test drilling inquiry

THE UK's first public inquiry into test drilling for the possible disposal of high level radioactive waste got off to a stormy start in Ayr, Scotland last week, with claims that the government was trying to cover up the real issues by restricting the type of evidence. The Scottish office has ruled that it will accept testimony only on the limited question of test site drilling. Community groups, fearing that limited approval for site drilling will create a precedent that will prejudice further hearings, have argued that evidence on the question of the suitability of the area for waste disposal itself ought to be admitted.

The inquiry had been set up to consider a planning application lodged by the United Kingdom Atomic Energy Authority two years ago to test drill an area of hard granite above Loch Doon in the Galloway Hills — possible sites in the UK for Britain's first underground radioactive waste repository. Soon after the planning application was lodged the local authority, Kyle and Carrick District Council, turned it down. The inquiry that opened in Ayr last week is the result of the UKAEA appealing against that decision.

The first witness, Scottish Under Secretary William Scott, stressed that the government had not yet decided on the best way of disposing of nuclear waste. Research was also planned on waste disposal on and under the sea bed, he said. Under cross examination Scott admitted that he could give no firm undertaking that all the other 15 shortlisted sites would be fully investigated at a cost of £1 million each.

Byron Lintern, a senior scientific officer from the Institute of Geological Sciences, and a witness for the UKAEA, explained that the proposed test drilling would involve sinking approximately 40 boreholes over a wide area at varying depths down to a maximum of 500m. Two 15m rigs would be needed and a staff of about 15. Drilling would be phased over a two or three year period to avoid disturbing local birds during their breeding cycle. The cost of test drilling had risen from £150,000 in 1978 to £450,000 in 1980, he said.

Dr Lewis Roberts for the UKAEA told the inquiry that the UK currently had about 1,000 m^3 of high level waste stored in steel tanks at Windscale. It was proposed to glassify the waste, encase it in non-corrosive metal and then find the most suitable place to store it. A safe home had to be provided for around 500 years, by which time gamma radiation would have decayed to acceptable levels. Roberts rejected Kyle and Carrick's suggestion that the drilling work was "premature."

● ONE of the main objectors at the formal inquiry, the Scottish Conservation Society, organised its own parallel hearing — the People's Planning Inquiry Commission — to discuss nuclear waste dumping, safety and alternative methods of disposal, topics forbidden at the main inquiry. 99% of those attending the 'People's Inquiry' were opposed to the drilling proposals.

The UKAEA declined an invitation to attend, but paid the expenses of Professor John Fremlin, a radiation biologist, who told the meeting that there was little likelihood of the proposed dump causing serious contamination. It would take 100,000 years for the waste to find its way to the surface, he said, and in the worst possible situation would only then result in one death per decade.

The Baltic

States cooperate to check sea pollution

WITHIN the next few days, West Germany, the last of the seven signatories to the Helsinki Convention on the Protection of the Marine Environment of the Baltic Sea area, is expected to deposit its instrument of ratification with the Finnish government. Two months from that day, the convention will come legally into force — the only such agreement to date to cover every aspect of the protection of the marine environment. The delay, caused by federal structure, has not, however, prevented the contracting countries from already embarking on a major programme of work on Baltic ecology.

The Baltic water is of exceptionally low salinity. This results in an ecology of low diversity, which is extremely vulnerable to environmental change. Accordingly, no sooner was the convention drafted in 1974, than a working party, the Interim Commission, was set up to carry out a number of preliminary tasks, including getting to grips with the scientific problems.

Foremost among such tasks is the permanent monitoring of the Baltic for pollution. The convention defines potential pollutants as hazardous (DDT and the PCB and PCT compounds), noxious (heavy metals, radioactive substances, etc) and oil. Seven of these have been selected as immediate priority areas (till 1983), with responsibility for research assigned on the lead country principle: Denmark for PCB and PCT's, West Germany for lead, East Germany for copper and zinc, Poland for DDT, USSR for mercury, Finland for oil, and Sweden for cadmium.

Basic research is not directly the concern of the Commission, although it does serve as a coordinator of the results of the environmental programmes of the individual countries. (Its cumulative bibliography of relevant publications in the Baltic countries since 1970 will be published shortly and there is a proposal to set up an international Baltic library). The main task of the Commission is to work out a coordinated monitoring programme, permitting the direct comparison of results.

A five-year pilot programme was initiated in March 1979. Sampling is to be carried out both at coastal stations and at specified locations at sea. Tests include both the physical monitoring of sea water parameters, and also biological specimens — notably herring, cod, *Macoma baltica,* eider duck, arctic tern and red breasted merganser. To ensure comparability, especially with the biological specimens, a massive file of methodological guidelines, covering all aspects from age and maturity of the specimens selected to test procedures and presentation of results, has been compiled. This is not yet in its final form, but, according to Dr Ilppo Kaugas, the scientific expert of the Interim Commission, only a very few minor comments and amendments have been proposed.

Intercalibration workshops form an important part of this monitoring programme. To date, these have included a chemical intercalibration workshop at Kiel in 1975 and one on biological calibration methods in 1979. A meeting on biomass, financed by the Commission and organised by Polish marine biologists, will be held in Gdynia in May of this year. In general, Dr Kaugas told *Nature*, the methodology for secondary production is still somewhat vague, and much work may be expected in this field in the future.

The most urgent problem, however, is that of oil spills and ship safety. In the narrow confines of the Baltic, even a close in-shore spill can affect the coasts and waters of other countries. The February 1979 spill of Ventspils harbour (Latvian SSR) ended up on the shores of Sweden and Finland. One recent idea, put forward by a Swedish team, is that all oil cargoes should be "tagged" by the addition of a mixture of metal particles. In the case of a spill, the relative composition of the tagging mixture could be determined by microscopic and mass-spectrographic methods, and this composition, which would be specific to each ship, would, when the convention comes into force, be considered as legal evidence, comparable to a fingerprint.

A large-scale international experiment on tagging methods was mounted last autumn, investigating such factors as the effect of climatic and meteorological factors on tagged oil. According to Dr Kaugas, the experiments were, in principle, a success, and similar methods "or possibly better" may well be introduced in the future.

Much attention is also being paid to general problems of ship-safety, including the logistics of long-distance pilotage of incoming tankers from the Kattegat to their home ports. One major problem facing the Commission is, however, that of ships sailing under the flags of countries not covered by the convention. "Everything depends in this case on the goodwill of the masters sailing under foreign flags", Dr Kaugas explained. For, although it was at the UN Conference on the Human Environment in Stockholm in 1972 that the Finnish delegation first raised the necessity of international action on the Baltic, and although it is proposed that, when the Permanent Commission is in operation, it will supply data from its monitoring programme to the UN Regional Seas Project, the Helsinki Convention is, essentially, a private agreement between the seven countries bordering the Baltic. The high standard of its monitoring work, and of its anti-pollution proposals (which, once it is signed, will be binding on the participating countries), may well, however, become a blueprint for other future international conventions on marine environments that would cover the whole range of sea-going nations. **Vera Rich**

NEWS IN BRIEF

US urged to spend more on space manufacturing research

UNLESS the US substantially increases the resources that it devotes to research on manufacturing techniques in space, it could see its national pre-eminence in space activities lost to the Soviet Union and Western European countries, according to a report published by the General Accounting Office, the investigative arm of the US Congress.

The report suggests that the federal government develop a plan for broad collaboration with private industry for research into ways of producing substances such as alloys, crystals, semiconductors, and high purity medicines and vaccines in a space environment. Private industry on its own "cannot be expected to risk high, long-term investments at the present stage of research," the GAO says.

The federal government should be speding two to three times the $20 million currently included in the budget for the National Aeronautics and Space Administration to support such research if it is to retain parity with other industrialised nations, the report says.

Three Mile Island birth defects

OFFICIALS of the Pennsylvania Department of Health confirmed last week that in the last nine months of 1979 13 hypothyroid babies were born in three neighbouring counties compared to an expected number of three such births. The odds against such an event occurring by chance are less than one in 10^5. Thyroid problems including hypothyroidism are known to be associated with exposure to I^{131} an isotope released into the atmosphere during the Three Mile Island accident. Officials said that likelier explanations than radiation exposure could account for the increase but that the timing was "peculiar and curious".

Supreme Court blow to campus unions

THE US Supreme Court dealt a damaging blow to attempts to unionise university faculty members when it ruled last week that an academic's involvement in managerial and administrative activities made him or her ineligible for collective-bargaining protection under federal labour law.

The Supreme Court's judgement was made on a case brought on behalf of the faculty of the Yeshiva University in New York City, by the National Labour Protection Board, which had argued that nothing in their responsibilities as educators precluded faculty members from attempting to resolve concerns about the terms and conditions of employment through collective bargaining.

In a five to four decision, the Supreme Court ruled against the NLPB that because universities had to rely on faculty members to participate in making and implementing decisions, for example over course content or the appointment of new faculty members, they were not entitled to the protection offered to industrial workers.

At present, 80 private universities have agreed contracts negotiated through collective bargaining. The court's decision means that in future university officials may be able to refuse to bargain with faculty unions.

French government starts troubled reactors

THE French Minister of Industry, Andre Giraud, authorised last week the start-up of the troubled French reactors, Gravelines I and Tricastin I. Instruments to monitor the growth of cracks 6mm deep and 7-8mm long in the tubular base plates of the primary circuit heat exchanger have been put in place and the ministry considers that the safety of the reactors is assured.

Dutch aerosol propellants ban imminent

DUTCH authorities expect to ban the use of chlorofluorcarbon (CFC) for aerosol propellants from the end of 1981, the Minister of Public Health and Environment, Dr Ginjaar, has said in reaction to reports from the American National Academy of Sciences (*Nature* 3 January, page 2). The member countries of the European Economic Community (EEC) agreed last year to a 30% reduction in propellant use by 1982. Next year the countries will review the position, and if a total ban is not agreed, the Netherlands will do it alone, possibly followed by West Germany.

According to Dr Ginjaar, only these two countries favour more stringent controls. In the Netherlands the use of CFCs as aerosol propellants have decreased by 30% already, and the authorities are now preparing a complete ban on non-essential uses. **Casper Schuuring**

Information withheld on nuclear waste shipments

KEEPING to the government's nuclear information policy of "no news is good news" (*Nature*, 13 December 1979 page 665), the UK Minister of Transport has refused to produce the names of towns and cities through which nuclear waste is regularly transported by rail. Mr Jack Ashley, MP (Labour, Stoke-on-Trent) received a reply to a parliamentary question from Mr Kenneth Clark, Parliamentary Secretary to the Minister of Transport, stating that the names were being withheld because "it would not be appropriate", to give them. Ashley was told, however, that regular nuclear waste shipments do pass through Stoke-on-Trent.

Nuclear waste transport has been a target for public protest in recent weeks (17 January page 238) causing some official discomfort. At a recent press conference held jointly by the Central Electricity Generating Board and British Rail to explain their position on the shipment of nuclear waste through London, it was revealed that an anti-nuclear campaign plan to stop one of the trains by civil disobedience may have been defeated by information provided by an informer. When asked to elaborate at a later time on the possibility that the CEGB had "its own moles" in the anti-nuclear movement, a CEGB official told *Nature* that the remark was "a light hearted aside" but added that citizens should tell police about wrong doings since "in this country we trust the authorities".

South Africa maintains nuclear weapons capability

A REPORT issued last week* claims that South Africa has developed and maintains a nuclear weapons capability "in order to preserve apartheid in the face of the changing balance of power in southern Africa". Based on a detailed study of South Africa's uranium producing facilities, the report claims that a pilot plant located at Valindaba has the facilities to produce uranium oxide, uranium hexafluoride and enriched uranium. Estimates of plant output since 1975 show that South Africa has accumulated enough enriched uranium to make 4 Hiroshima sized bombs or 12 smaller devices in the 4 kiloton range. Delivery systems would be South Africa's British made Bucanneer and Canberra jets.

In the meantime, confusion exists about responsibility for waht is thought to have been a nuclear explosion off the Cape of Good Hope on 22 September 1979. According to information released by the CIA the explosion has been identified from three independent instruments — the radio telescope in Arecibo, Puerto Rico and two independent observations from the Vela spy satellite. The CIA attributes the bomb to South Africa but a book authored by two Israelis published last week claims that the bomb was an Israeli device exploded with South African facilities.

INFCE brings international agreement on nuclear fuel cycle no nearer

[illegible]
[illegible]
Upper Circular Road
[illegible]

THE International Nuclear Fuel Cycle Evaluation (INFCE) was set up to release growing tension between states over control of the nuclear fuel cycle and the possible spread of nuclear weapons, but, argues **Ian Smart**, without political agreement between governments INFCE alone could not do this

AFTER two and a half years of discussion INFCE has reached its public end with a final plenary session in Vienna. It was bred to be a dispassionate technical analysis of future fuel cycle options in the light of proliferation concerns. How well it has performed will now be tested. Assessments will inevitably vary, if only because different governments looked to INFCE to achieve different things. Especially at the outset, the United States, for example, looked for persuasive evidence that there would be sufficient newly-mined uranium to make reprocessing and the deployment of fast breeder reactors unnecessary for the foreseeable future, and that civil nuclear technology could be developed in 'proliferation-resistant' directions which avoided the presence of separated plutonium.

Others looked for some sort of contrary technical demonstration: that spent fuel would have to be reprocessed to reduce pressure on uranium supply or to make nuclear waste manageable; that plutonium could and should be used in existing thermal reactors; that fast breeder reactors would be needed as quickly as they could be developed; that there were technical means of making any of those activities resistant to proliferation. As the findings of INFCE are studied, it will be found that none of the participants got all it wanted. There is no firm agreement on the future availability of uranium, for example, nor therefore on the rate at which reprocessing should be undertaken or breeder reactors deployed. Indeed, about the only clear conclusions of the technical evaluation are that no conceivable fuel cycle could much reduce the possibility of proliferation and that no single pattern of technical evolution could be appropriate to all national circumstances.

But many of the 46 participating governments have learned something from it on the technical level, and now understand more about the difficulties of both nuclear fuel cycles and proliferation. One part of INFCE's paradox, however, is that technical experts, dealing with issues many of which were essentially economic, contrived, above all, to achieve a political effect. What they demonstrated, in fact, was that the principal issues raised by a possible relationship between civil nuclear fuel cycles and the proliferation of nuclear weapons cannot be resolved by technical ingenuity or arbitrary government intervention, but only by political negotiation and political agreement.

INFCE can best be regarded as a course of drug therapy, administered to the fevered body of international nuclear energy relations. Partly by that means, the patient's temperature has been reduced. The pathology, however, remains unchanged. The prognosis must therefore be that, the drug having been withdrawn, the temperature will rise again unless the basic disease is identified and treated — and the one thing INFCE has achieved in that connection is to establish that both diagnosis and cure must be political.

The one achievement of INFCE which may, perhaps, be forgotten in a flood of technical commentary is that, simply by meeting for more than two years, it has helped to dissipate the fierce antagonisms that have developed among nations in the nuclear fuel cycle trade.

INFCE arose from international turmoil. At the end of the 1960s, the Non-Proliferatin Treaty (NPT) expressed a new international consensus on the need to expand peaceful uses of nuclear energy without increasing the number of countries controlling nuclear weapons. Provided countries without weapons — non-nuclear-weapon states — substantiated their renunciation of them by permitting international inspection, the treaty acknowledged their right to develop nuclear energy for peaceful purposes without further restriction. The NPT was never universally accepted, but, backed by the safeguards system of the International Atomic Energy Agency (IAEA) and supported by a large majority of governments, it offered some hope of setting the general standard for international behaviour. Five years later, however, both the standard and the hope lay wounded.

> 'The temperature has been reduced . . . but the pathology remains unchanged'

In 1974, India, which had not accepted the NPT, tested its first nuclear explosive. Almost simultaneously the Nixon Administration offered power reactors to Egypt and Israel, despite the fact that neither was a party to the NPT. Another nuclear-weapon state, France, having refused to sign the NPT, was negotiating sales of reprocessing technology to both Pakistan (which had also rejected the NPT) and South Korea. West Germany, agreed to provide yet another NPT non-party, Brazil, not only with reprocessing technology but also with equally 'sensitive' equipment for uranium enrichment. And meanwhile the oil crisis was exciting interest in nuclear power and persuading many of those committed to it to seek self-sufficiency.

Shocked by the Indian experience, and fearful that their commercial rivalry, if uncontrolled, might encourage a dangerous increase in the number of countries able to produce weapons, the major governments involved in nuclear exports formed the Nuclear Suppliers Group (NSG) and (secretly) agreed in 1975 on a set of guidelines to govern the export of 'sensitive' items. Although the suppliers eventually published these rules, in 1978, the fact that they had drawn them up in secret and without wider consultation aroused the resentment and apprehension of their customers, especially in the Third World. As to the substance of the NSG guidelines it was soon recognised that they went beyond the NPT itself, by calling for restrictions on the international transfers of certain allegedly 'sensitive' fuel cycle technologies such as enrichment and reprocessing, by limiting the use which those who did import such technology might make of it, and by recommending

---

Ian Smart is an adviser on international energy affairs

0028-0836/80/09808-02$01.00

that exporters of nuclear fuel should retain the right to veto any reprocessing of it after use.

There was a widespread impression that the guidelines discriminated against the less developed nuclear countries, and that, by implying such countries had no general right to enrich uranium or reprocess spent fuel, even under safeguards, they made nonsense of a fundamental NPT concept. The NPT consensus had been founded on the idea that, for all non-nuclear-weapon parties, all peaceful and safeguarded nuclear activities were equally legitimate. Now it was said that some non-nuclear-weapon states — and some peaceful technologies — were more equal than others.

These resentments were compounded in April 1977, with President Carter's announcement that the US would indefinitely defer reprocessing and the use of plutonium, and would also hold back development of fast reactors capable of 'breeding' plutonium. At the same time, it would withhold approval for foreign reprocessing of US-origin nuclear fuel. Such a policy, subsequently reinforced by the US Congress in the Nuclear Non-Proliferation Act, could be seen as a logical extension of the NSG guidelines. It now struck, however, not only at the transfer of reprocessing (or enrichment) technology but also at the conduct of reprocessing by those who already possessed the capacity: by Britain and France, which had plants, and by West Germany and Japan, which were seeking to build them. The effect was to divide the suppliers against themselves.

The overall result, by the spring of 1977, was that commercial and political confidence in the whole field of international nuclear relations was at a nadir. Contracts had been suspended. Bilateral agreements had been unilaterally recalled, in mid-term, for renegotiation. Multilateral agreements, such as the NPT, had become playthings for minority interpretation. North-South nuclear relations were already embittered, and relations between developed countries were now becoming openly acrimonious. Some cooler review of proliferation issues was urgently needed, if rampant frictions were not to destroy the fabric of international cooperation and trade.

So INFCE was conceived at the the May 1977 Economic Summit in London, and officially born in October of that year in Washington. Its eight working groups, with the Technical Co-ordinating Committee (TCC) composed of their 22 co-chairmen, have since held 70 meetings and produced 20,000 pages of commentaries and drafts. Now it is winding up, with a final plenary session whose task this week is to set its seal on the lengthy 'Overview' agreed in the TCC and on the even longer reports of the separate working groups. And next come the consequences of its three years' work.

> 'Nothing less than the world pattern of nuclear energy development is at stake'

> 'As the findings of INFCE are studied, it will be found that none of the participants got all they wanted'

In the short term, international nuclear relations will inevitably come under renewed pressure. In several countries — Sweden and West Germany, for instance — the link between nuclear power and proliferation is an immediate issue in domestic politics. In several cases, as between the United States and Japan or the United States and Euratom, bilateral arrangements for nuclear cooperation and trade must now be re-cast in more restrictive form. And in August 1980, at the multilateral level, parties to the NPT must meet at their second Review Conference, where the political tensions unresolved by INFCE will again be prominent. Unless those and other immediate stresses are successfully absorbed, the temperature of international nuclear relations could easily be rising again by the end of the year.

Looking to the longer term, the problem is simpler but more difficult. What has collapsed since 1974 is not some set of formal rules or standards but rather the sense of international confidence: confidence that nuclear power can be used more widely without intolerably increasing the risk or fear of weapons proliferation; confidence that international contracts and agreements will be fulfilled, and that all those who seek the energy benefits of nuclear power will be able to draw equitably on international trade under safeguards.

As a result, nothing less than the world pattern of nuclear energy development is at stake. On one side, there is a model of development in which countries committed to nuclear energy programmes, but unconvinced that essential goods and services will always be available on acceptable terms, are driven to seek nuclear autarky as the only other route to energy security. With little regard to cost, more of them will then for instance, acquire their own plants for enrichment and reprocessing.

On the other side is a model of inter-dependent development, in which the same countries, offered a reliable system of nuclear trade and cooperation, will voluntarily optimise their programmes within a regional or global context. Political and economic rationality will then coincide to produce an efficient international distribution of labour in the nuclear fuel cycle, including its 'sensitive' stages.

The former pattern of 'fragmented autarky' would clearly generate greater fears of proliferation, while also being resistant to internationally agreed regulation or safeguarding. The paradox of some supplier policies since 1974, however, is that, by seeking to restrict nuclear trade and confine fuel cycle technology and capacity to a few countries in the name of non-proliferation, they have reduced the confidence of other states in inter-dependent development and actually increased the pressure on them to move to 'fragmented autarky', making the system progressively less amenable to international regulation.

The privately sponsored International Consultative Group on Nuclear Energy, in its recent report, has called for "a new 'bargain of confidence', in which credible guarantees of peaceful purpose will be balanced by firm assurances of access to nuclear services, materials and technology". Such a bargain of confidence can only be achieved by political negotiation. Non-proliferation treaties and international safeguards provide a starting point, and INFCE may offer some signposts. Experience of the last decade proves, however, that more is needed: some general code of conduct for international nuclear trade, agreed by importers as well as exporters, and possibly some more imaginative institutional arrangements for the international management of 'sensitive' activities and materials.

The alternative is not to be contemplated. Ten years ago, governments made the mistake of turning away from the NPT before its general provisions had been converted into concrete and equitable arrangements suited to specific international circumstances. INFCE has solved nothing, but it has bought an opportunity to repair some part of that gross error. If governments, especially in the advanced nuclear countries, fail to build onwards from INFCE into a lattice of political negotiation, design and agreement, they will have only themselves to blame if, in another few years, international nuclear relations are again as inflamed and painful as they were when it started. □

In *Nature* next week Sir Hermann Bondi, chief scientist at the UK Department of Energy and leader of the UK delegation to INFCE over the past two years, explains how INFCE reached its technical conclusions.

CORRESPONDENCE

Iraq's efforts to reverse the brain drain

SIR, — I was very pleased with Ziauddin Sardar's article in *Nature* (January 24, page 327) in which the author goes into depth in an effort to describe the exporter and importer countries of scientists and the problems these scientists face in the host countries. Although the report reflects the realities in these countries, it failed to mention anything about Iraq, a country that has a very clear policy in attracting expatriate scientists to return and establish residence in Iraq. In fact as early as 1974, the Revolutionary Command Council of Iraq instituted the "law of return" to any Arab scientist, engineer or holder of a high university degree to return to Iraq. The government, on its part, provided the returning scientists with several enticements including:

- all the facilities needed to do science
- an option to acquire the Iraqi citizenship after a year's stay
- a lot of land to build a house
- a substantial, long term, interest-free loan to effect the building of the dwelling.

Iraq's ambitions to foster science and technology is evident by the construction of new universities and science centres, in recent years, to accommodate the returning scientists as well as to accommodate the ever-increasing number of graduates sent to various developing countries for higher studies and training.

The development of science and technology receives support at the highest levels. Indeed Mr Saddam Hussain, the President of Iraq, gave his clear instructions to do what it takes to develop the scientific base in Iraq. He personally authorised the establishment of a new programme of short-term training seminars to be held in Iraq at government expense. The trainees are Iraqi and other Arab nationals and the training staff are scientists residing in the western world. I personally, along with my colleagues of the Arab American University Graduates (AAUG) had the opportunity to conduct some of these seminars in Baghdad, under the auspices of the Ministry of Health.

Because of its pan Arab nationalistic policy, the government of Iraq insists that "Iraq is for Arabs". This policy is translated into action by waiving the visa requirements to any Arab national, wherever he lives, and who wishes to visit, work or establish a home in Iraq. To my knowledge this is the only Arab country that has felt secure and abolished the visa requirements. To further promote the feeling that Iraq is for Arabs, the non-Iraqi Arab nationals are treated as equal to their Iraqi counterparts. The treatment of "second class citizens" of the expatriates mentioned in Sardar's article is non-existent in Iraq. One can safely deduct that Iraq's long-term ambitions are to bring Baghdad to its golden days as a centre of science and technology.

I am neither an Iraqi national nor a member of the ruling political party, but a concerned Arab scientist residing in the United States and currently on short leave in Switzerland.

Defending democracy or something else?

SIR, — Your correspondent (Rolf Seifert, 31 January, page 426) alludes to the "suicide of democracy" if "disruptive Marxists" are allowed to occupy "influential positions" in society. According to cases we are actually involved with, "influential positions" include postmen, railwaymen, teachers of educationally subnormal children and civilian army cooks as well as the cases quoted in *Nature* (6 December, page 549).

It is the suicide of democracy for the state to monitor legal involvement in the democratic process, to label them arbitrarily as 'disruptive', and then continue to use them as a criteria for the dismissal of long-standing public employees from their jobs. When you defend democracy by such methods, you do not defend democracy, you defend something else.

There is an old English proverb about killing the goose that lays the golden eggs.

Nuclear safety conference open to the press

SIR, — In "News in Brief" (24 January, page 326) you mention the IAEA's International Conference on Current Nuclear Power Plant Safety Issues, to be held in Stockholm from 20-24 October 1980, with a misleading title. I would like to make the following points:

- This conference, like all others organised by the Agency, is open to the press and to the public, accommodation in the conference hall permitting.
- The requirement that papers be submitted by governmental designees is a standard requirement for all meetings of the United Nations and its agencies, since they are intergovernmental bodies, and in practice, therefore, these papers represent a wide range of opinions.

GEORGES DELCOIGNE

Makerere University library appeal

SIR, — We would like to bring attention to some of the difficulties currently being faced by Makerere University in Uganda, particularly with regard to the university's library. All finance for the library was cut off in 1974, and in the last few months since the liberation only a portion of it has been restored. In consequence all runs of the 2000 or so learned journals which the library used to take ceased, as did the purchase of new books. Moreover during the recent fighting many books and much library equipment were looted.

A university cannot function effectively without a good up-to-date library, and teaching and research must both be severely hampered. Makerere used to have one of the best libraries in East Africa, housed in a beautiful building, and both of us have in the past spent many peaceful hours working in it. We have therefore decided to open a fund to help re-equip the library, and we appeal to all those with an interest in Makerere and a concern for education in Africa to contribute generously. We will ensure that the fund is used for the designated purpose by consulting with the librarian and then purchasing and despatching books to him. If you would like to help please send a cheque made payable to the "Makerere Library Fund" to one of us at the address below.

Maoist dogma clashes with fair appraisal of science

SIR, — I deplore the descent of *Nature* into the murky realms of propaganda. A series of feature articles on Chinese science by Tong B. Tang published in the 31 January, 7 February and 14 February issues use the most blatant political jargon, something totally unsuited to a scientific periodical. The epithet 'Gang of Four', a political insult which would not be out of place of George Orwell's book *1984*, 'revisionism', 'capitalist roaders' and other jargon, combined with Maoist unintelligibles like "one divides into two" combine to make the articles unpalatable. Surely the peculiar outpourings of Maoist dogma clash with a fair and dispassionate appraisal of progress in Chinese science. The 'ascent of deviationists' may be of interest to the changing policies of Marxist doctrinal quibblers, but such extravagant phraseology masks what is really the issue — the use of science for political ends. Like so-called Islamic science or even Christian science, these 'sciences' which are oriented to some prearranged goal like the 'dialectics of nature' serve only to bolster the preconceptions and prejudices of dogmatic plutocrats.

NIGEL PENNICK

Critic of "The Sirius Mystery"

SIR, — Robert K. G. Temple's long letter (17 January, page 242) seems to have been, in part, motivated by a sense of indignation at not having been appropriately cited by Rowan-Robinson (in his review of Carl Sagan's "Broca's Brain", (8 November, page 176) nor by Carl Sagan (in his book "Broca's Brain").

It is therefore worth pointing out that Temple himself carefully avoids any reference to articles critical of the claims he makes in his book "The Sirius Mystery." One such article that readers of *Nature* might wish to know about is Pesch, P. and Pesch, R. *The Observatory,* **97,** 26; 1977.

PETER PESCH

Transposable mating-type genes in yeasts

from Urs Leupold

THE genetic analysis of the inheritance of yeast mating types has developed recently from a rather specialised subject studied by only a small group of yeast geneticists into one of central genetical interest. This is due to the growing realisation that the mating type switches observed in both *Saccharomyces cerevisiae* and *Schizosaccharomyces pombe* are yet another example of the phenomenon of transposable or translocatable genes whose importance is increasingly being recognised throughout the living kingdom.

Saccharomyces cerevisiae

In *Saccaromyces cerevisiae* there are two mating types *a* and *α*. Vegetative haploid cells of opposite mating type can fuse to form vegetative diploids which may subsequently sporulate, producing haploid spores. In homothallic strains of *S. cerevisiae* haploid cells of one mating type can 'switch' mating type during vegetative growth, giving rise to progeny of the opposite mating type.

In *S. cerevisiae,* the results of the genetical analysis of mating-type interconversions in homothallic and heterothallic strains have led I. Herskowitz and coworkers to develop a hypothesis known as the 'cassette model' to explain the observed interconversions (reviewed by I. Herskowitz *et al.* in *The Molecular Genetics of Development,* ed. Loomis, W. & Leighton, T., Academic Press, 1979). Briefly, this model proposes that the switching between the two opposite mating types *a* and *α*; which occurs as frequently as every cell division in homothallic strains, is due to the transposition of *α* and *a* alleles from silent storage sites to the mating-type locus where they replace the allele present, either *a* or *α*. The storage sites carrying either an *a* or an *α* allele in an unexpressed form have been characterised genetically as two gene loci *HML* (carrying the *α* or, less frequently, the *a* allele) and *HMR* (carrying the *a* or, less frequently, the *α* allele). The two loci map far from the mating-type locus *MAT* but in the same chromosome on opposite sides of *MAT* (*HML* in the left and *HMR* in the right arm) (see Fig. 1). In the presence of the *HO* gene for homothallism which allows for frequent switching (as opposed to the rare mating-type interconversions observed in heterothallic strains of constitution *ho MATa* and *ho MATα*), defective mutant alleles of the type *mata*$^-$ or *matα*$^-$ are quickly replaced by the corresponding functional alleles which are stored in a silent form at the *HML* and *HMR* loci. Mutations induced in the *HML* and *HMR* loci can also be transposed to the *MAT* locus by switching. This transposition is a long-range transfer and seems to occur also in the *trans* configuration between different (homologous) chromosomes.

A recent paper by J. Hicks, J.N. Strathern and A.J.S. Klar (*Nature* **282**, 478; 1979) offers physical evidence for the existence of homologous sequences at the *MAT, HML* and *HMR* loci which is entirely consistent with the cassette model. Moreover, it shows that this homology is not restricted to alleles which determine the same mating type (for example *MATα, HMLα, HMRα*) but that even alleles determining opposite mating types (for example *MATα, MATa*) share homologous sequences. DNA restriction fragments carrying an *α* allele of either *MAT, HML* or *HMR* differ however from restriction fragments carrying *a* alleles in being uniformly about 200 base pairs larger. Both homothallic (that is, frequent) and heterothallic (rare) mating-type interconversions involve a corresponding change in size of the restriction fragment carrying *MAT*. This shows that the

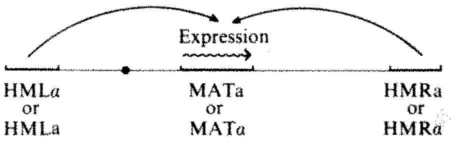

Fig.1. Relative arrangements of HML, MAT and HMR on chromosome III of *S. cerevisiae.* During mating type interconversion a copy of *a* or *α* is inserted into the MAT locus where it is expressed. The sequence previously located at the MAT locus does not reappear in the genome and is presumably lost. (After Hicks *et al. Nature op. cit.*)

interconversion process involves a rearrangement of the DNA sequences present at the *MAT* locus, most probably the substitution of an *a* or *α* sequence by a partially homologous *α* or *a* sequence from one of the silent genes *HML* or *HMR* as predicted by the cassette model.

These remarkable results have been obtained by cloning a 6.6 kb *Bam*H1 restriction fragment carrying an *α* allele sequence (the *HMLα* allele) on a plasmid capable of replicating in both yeast and *E. coli* and of transforming yeast at high frequency. The cloned sequence was identified by its ability to complement a defective *mat* allele for both mating and sporulation when plasmid DNA carrying the *α* sequence was introduced into cells carrying the mutant allele at the *MAT* locus. When this plasmid was used as a hybridisation probe against Southern blots of restricted DNA from a series of different yeast strains carrying known mating-type alleles at the mating-type locus *MAT* and the two silent loci *HML* and *HMT,* characteristic differences in restriction patterns between *a* and *α* strains were observed. In tetrad analyses of meiotic crosses between strains differing in their mating-type constitution at either the

Urs Leupold is Professor of Microbiology at the University of Berne.

0028-0836/80/09811-02$01.00

mating-type locus or one of the silent loci, these differences segregated along with the mating-type alleles studied.

Klar, Hicks, Strathern and J. Broach have presented these results at a meeting on the Molecular Biology of Yeast which took place in Cold Spring Harbor last year. There they presented additional evidence (not mentioned in the paper) based on heteroduplex mapping which shows that the *α* allele differs from the *a* allele not only in the addition of a sequence of about 200 base pairs but also in the substitution of an adjoining sequence of about 700 base pairs. The heterologous region (700 bp in *a* and 900 bp in *α*) is flanked on both sides by homologous regions which permit hybridisation between complementary *a* and *α* strands.

These findings have independently been confirmed and extended by K.A. Nasmyth and K. Tatchell who have cloned the *α* sequence from the *MAT* locus and who have also discussed the results of a heteroduplex analysis of the three mating-type genes at the same meeting. A paper presenting their data will shortly be published (*Cell,* in press). A heteroduplex analysis of the six possible combinations between purified *Hin*d III fragments carrying *MATα, MAT*a, *HMLα* or *HMRa* showed that the homologous regions common to all loci are confined to two blocks of DNA, one of 230 base pairs located on one side (the 'left' side) and one of 700 base pairs located on the opposite side (the 'right' side) of the *a/α* specific sequence of approximately 800 base pairs (700 bp in *a* and 850 bp in *α* according to their data). The *a* and *α* specific insertions are present in the same orientation, with respect to the two homology blocks, in active and silent loci. *HMRa* lacks an extensive 700 bp DNA sequence to the right of the large right hand homology block and probably also a small (100 bp) sequence to the left of the small left hand homology block, both of which are present at *MAT* and *HMLα* (see Fig. 2). In *MATa* and *MATα*, the regions of homology flanking the *a/α* specific sequence extend to the ends of the 4.1 kb and 4.3 kb *Hind* III fragments carrying the *a* and *α* alleles of the *MAT* locus.

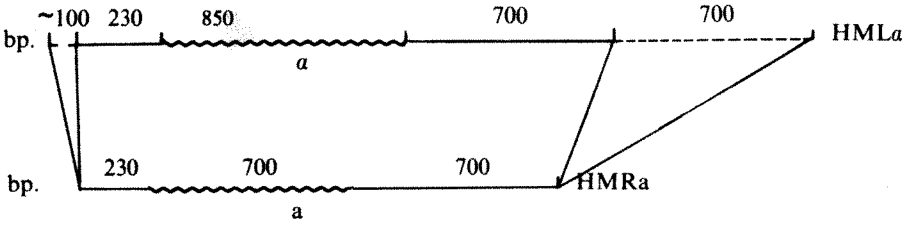

Fig.2. Schematic representation of the differences between HMLα and HMRa (see text for explanation).

On the basis of these data, the extent of the sequence transposed from *HMRa to MATα* in an *α→a* switch seems to be at least 700 bp and at most 230 + 700 + 700 = 1,630 bp. In an *a→α* switch, the sequence transposed from *HMLα* to *MATa* consists of a minimum of 850 bp but may include as many as 100 + 230 + 850 + 700 + 700 = 2,580 bp. The extensive sequence homology shared by the active mating-type locus *MAT* and the silent loci *HML* and *HMR* suggests that the interconversion replacing the resident mating-type sequence at the *MAT* locus by an alternative sequence from one of the two silent genes may occur by a mechanism of non-reciprocal gene conversion. This would involve an intrachromosomal alignment of active and silent loci of opposite type, followed by the transfer of a single-strand DNA segment from the silent to the active locus where it replaces the corresponding segment including the central sequence of opposite mating-type specificity. The resulting heteroduplex structure containing an unpaired loop in the centre of the MAT locus could then be resolved either by local excision repair which replaces a DNA segment of the resident *MATa* or *MATα* strand by a complementary copy of the transferred *HMLα* or *HMRa* single-strand segment, or by normal DNA replication with leads to the segregation of two daughter chromosomes carrying alleles of opposite mating-type specificity at the active mating-type locus. The recent finding of R.E. Malone and R.E. Esposito (also reported at the Cold Spring Harbor yeast meeting mentioned above and see *Proc. natn. Acad. Sci. U.S.A.* **77**, 503; 1980) that a DNA repair mutant defective in both meiotic and mitotic recombination (*rad*52-1) prevents homothallic switching, lends direct support for the involvement of generalised recombination functions in the mating-type interconversions observed in yeast.

Together, the two reports from the groups of J. Hicks and coworkers in Cold Spring Harbor and of K.A. Nasmyth and K. Tatchell in Seattle represent the first physical evidence confirming the genetical evidence that the two silent mating-type loci *HML* and *HMR* show an extended sequence homology with the active mating-type locus *MAT* and with one another when carrying alleles of the same mating-type specificity, either *a* or *α*. They demonstrate further that even when carrying alleles of opposite mating-type specificity, the three loci share homologous sequences although their *a* and *α* alleles differ in a central region of 700 and 850 base pairs, respectively. Together with the genetical evidence obtained by the group of I. Herskowitz at the University of Oregon and by many others, they provide very strong support for the cassette model which proposes that the mating-type interconversions in yeast are due to the transposition of mating-type alleles from silent storage sites ('cassettes') to the mating-type locus where they become expressed.

The mating-type locus plays a key part in the differentiation of yeast cell types for it controls not only mating but also sporulation. Diploid cells homozygous for the *a* or *α* allele at the mating-type locus *MAT* can mate with cells of the opposite mating type but are unable to undergo meiosis and sporulation. Diploid cells of heterozygous constitution *MAT*a/*MATα* can be induced to undergo meiosis and sporulation but are unable to mate with either *a* or *α* cells. An understanding of the role of gene transposition in the differentiation of these yeast cell types may well contribute to a future understanding of cell differentiation in higher eukaryotes (see I. Herskowitz *et al. op. cit.* 1979).

Schizosaccharomyces pombe

Mating-type switching in *Schizosaccharomyces pombe* (see Egel *Nature* **266**, 172; 1977), although still in the purely genetic phase of research, has recently been shown to resemble 'cassette-recording' in *Saccharomyces,* partially at least (R. Egel, Copenhagen, as presented at the Cold Spring Harbor meeting). One of the two closely linked mating-type genes found in this species, *mat2-P,* has turned out to represent the silent store of 'plus' information, which can only be activated by copy-transposition to *mat1* — the 'mating-type locus'. The 'minus' information residing at *mat1-M* beforehand is formally replaced by the inserted *P* copy, but whether this is merely due to transient separation of *M* from its controlling signal or whether the *M* segment is, in turn, excised is still unknown. In the latter case another gene of silent *M* storage should exist elsewhere, for which there is as yet no evidence. A major difference remaining (relative to *Saccharomyces*) lies in the fact that this *P* transposition requires the close linkage here encountered and does not function in the *trans* configuration. This linkage and the *cis* effect have hitherto obscured the activation mechanism of the *P* gene, which only revealed itself after mutants had become available that reduce the naturally high frequency of switching. In such mutants the activated (transposed) *P* copy remained in place long enough to be detected. Otherwise it was lost too soon (within 1-3 cell divisions) by the next switch-back reaction. □

Interstellar grains in meteorites?

from R. Hutchison

TODAY, the most favoured theory of the origin of the Solar System entails the collapse of a gas-dust cloud, perhaps initiated by a shock-wave from a nearby supernova. Heating during the collapse phase would have vaporised much, if not all, of the pre-existing dust. The question then arises: did any of the presolar dust-grains survive? And if so, how might they be recognised? Answers to these questions may be found in carbonaceous chondrite meteorites.

Evidence that some materials are enriched in the products of a supernova (or supernovae) was found in inclusions in the Allende meteorite. The scientific community was extremely lucky to receive two tonnes of specimens from the Allende meteorite shower that fell in northern Mexico in February, 1969, making available for study kilograms of samples of a type which had previously been doled out in gram-sized amounts. The Allende material was found to contain whitish inclusions consisting of minerals rich in calcium, aluminium and titanium. Such mineral assemblages were soon recognised as those predicted by Lord in 1965 (*Icarus* **4**, 279) as the first material to condense from a cooling gas of solar composition. And in 1973, R.N. Clayton *et al.* (*Science* **182**, 485) established that the oxygen of the high temperature inclusions and chondrules of Allende and related carbonaceous chondrites is enriched in pure ^{16}O. It was argued that the pure ^{16}O was produced by nuclear processes in an expanding outer shell of a supernova. Soon after the pure ^{16}O was introduced into the Solar System, condensation of refractory minerals trapped a portion of the pure isotope, the remainder having been mixed in with average Solar System oxygen, so losing its identity.

Further studies revealed that the white, calcium, aluminium, titanium-rich inclusions of Allende have anomalous isotopic abundances of various elements. Potentially, the most important of these anomalies is in ^{26}Mg because this is the daughter isotope of ^{26}Al, of which the half-life is only 740,000 years. The ^{26}Mg anomaly was discovered by Gray and Compston (*Nature* **251**, 495; 1974) and by Lee and Papanastassiou (*Geophys. Res. Lett.* **1**, 227; 1974). Wasserburg's group soon showed that in several Allende inclusions there is an internal isochron relationship between ^{26}Mg/^{24}Mg and ^{27}Al/^{24}Mg (*Geophys. Res. Lett.* **3**, 109; 1976). The isotope ^{27}Al is the only stable isotope of the element, and ^{24}Mg is the most abundant common isotope of magnesium. Thus, in each mineral of some inclusions there is a positive correlation between ^{26}Mg and the aluminium to magnesium ratio. We can therefore conclude that these inclusions crystallised when ^{26}Al was still extant. But, as D.D. Clayton has pointed out, there is no positive proof that the white inclusions crystallised within the Solar System (see for example *Nature* **257**, 36; 1975). Because isotopic anomalies of different elements, but especially light and heavy elements, do not generally correlate with each other, it is argued that crystallisation of the white inclusions must predate the Solar System. Injection of newly synthesised nuclides from a supernova into a presolar gas-dust cloud should have caused complete mixing of the injected elements. Thus, any isotopic anomalies should be correlated within each white inclusion. Lack of such correlation may be interpreted as indicating that the white inclusions represent condensates from the outer shells of the expanding supernova itself, assuming that the shells are blown concentrically outwards with a minimum of mixing between them.

Last year, a presolar age for two Allende inclusions was given a boost. Jessberger and Dominik (*Nature* **277**, 554; 1979) found that two inclusions have ^{39}Ar–^{40}Ar ages of about 5.0 Ga. The technique uses the ^{40}K–^{40}Ar decay scheme, but ^{40}K is estimated from the amount of ^{39}Ar produced by neutron irradiation of ^{39}K. If the ^{40}K/^{39}K ratio throughout the inclusion had been uniformly high, it could have accounted for the apparently old age. However, Stegmann and Begemann (*Nature* **282**, 290; 1979) found the potassium isotopic ratios to be normal. Thus the inclusions seem to have crystallised 400 Ma before the birth of the Solar System. But because other age determination techniques give a 'normal' age of about 4.55 Ga for Allende and its inclusions (see for example Tatsumoto *et al. Geochim. cosmochim. Acta* **40**, 617; 1976 and Chen and Tilton, *ibid.*), the ^{39}Ar–^{40}Ar age is still treated with suspicion. Even so, there seems to be a good chance that in some of the Allende inclusions we have presolar aggregates of refractory minerals up to about 1 cm in diameter.

Other approaches in the search for presolar, interstellar grains have been taken by Anders' group at Chicago and Eberhardt's at Bern. In 1969, Black and Pepin argued by a process of elimination than an anomalous neon component in some meteorites is of presolar origin (*Earth planet. Sci. Lett.*, **6**, 395; 1969). This type of neon, 'Ne-E', is characterised by low ^{20}Ne/^{22}Ne and ^{21}Ne/^{22}Ne ratios; Ne-E is, therefore, highly enriched in ^{22}Ne. Because noble gases are released from mineral grains at moderate temperatures, any carrier of Ne-E could not have had a high temperature history like that of the Allende inclusions. So, if the carrier minerals of Ne-E could be separated and identified, this might provide a sample of interstellar grains. To this end the Chicago group used chemical separation techniques and the Bern group physical methods.

Lewis *et al.* of Chicago (*Astrophys. J. Lett.* **234**, 165; 1979) used a sample of the water-bearing, CM2, carbonaceous chondrite which fell at Murchison, Victoria, Australia in September, 1969. As with Allende, scientists were fortunate to have been provided with about 500 kg of a type of meteorite which had previously been in short supply. The Chicago group dissolved away over 99.7% of their sample, using various reagents including HF, HNO_3, NaOH and H_2O_2. The residue was split into three size-fractions and from aliquots of each the rare gases were extracted by stepwise heating. Isotopic ratios were measured in the gas released at each heating step. Ne-E was released from the coarse (>3μm) fraction in two steps at 800 °C and 1,200 °C. Low-temperature (800 °C) release was not observed in an aliquot of material which had been treated with $HClO_4$. The low temperature carrier destroyed by $HClO_4$ was thought to be an oxidisable, carbon-rich material. From previous work and from its resistance to attack, the high temperature carrier of Ne-E was tentatively identified as spinel ($MgAlO_4$). In addition to carriers of Ne-E, a carrier of *s*-process xenon was identified as a carbon-rich phase stable at 1,400 °C. Lewis *et al.* concluded that the two carbonaceous phases and spinel are 'extrasolar'. However, stability of spinel requires a more oxidising environment than phases rich in elemental carbon. The authors, therefore, speculated that the extrasolar minerals may be condensates from red giants "at different stages of evolution".

The Bern group prepared nine density fractions of the Orgueil, water-bearing, carbonaceous chondrite, and stepwise heating was used on all but one, which was too small (*Astrophys. J. Lett.* **834**, 169; 1979). Ne-E was most highly concentrated in the least dense fraction (<2.3 g cm^{-3}), from which it was released below 900 °C. From three high density fractions (total range, 2.9–3.6 g cm^{-3}) Ne-E was mostly released at about 1,200 °C. Because potential contaminants are of lower density, it was argued that the Ne-E carrier probably has a density of about 3.5 and is probably spinel. Eberhardt *et al.* point out that the low density fraction has a low content of cosmic ray-produced ^{21}Ne, which indicates a low abundance of the target elements Mg, Al and Si, and is consistent with a carbon-rich composition. Furthermore, the composition argues against the possibility of the *in situ* production of pure ^{22}Ne by particle bombardment within the Solar System. A presolar origin of one Ne-E carrier therefore seems assured. □

R. Hutchison is in charge of the national collection of meteorites in the British Museum (Natural History), London.

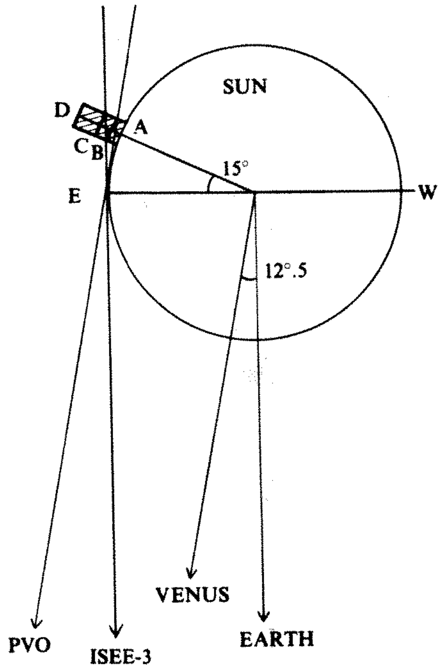
The hard X-ray Sun in stereo

from John C. Brown

VIRTUALLY on the eve of launch (14 February, 1980) of the first ever solar hard X-ray imaging telescope, aboard NASAs Solar Maximum Mission (SMM), a group of US researchers has scooped some of its expected results without the use of imaging instruments. Kane and Anderson of Berkeley and Evans, Klebesadel and Laros of Los Alamos (*Astrophys. J. Lett.* **233,** L151; 1979) have obtained quantitative information on the spatial structure of a solar hard X-ray source by simultaneous observations from two separate spacecraft. Their results provide invaluable insight into the process of electron acceleration which is central to the solar flare problem.

At the time of observation (5 October, 1978 around 0632 UT) an International Sun Earth Explorer (ISEE-3) was located near the Earth while Pioneer Venus Orbiter (PVO) was 12.5 degrees eastward as seen from the Sun (see Figure). Fortuitously, a flare occurred in an active region A some 15 degrees behind the solar limb which consequently occulted different parts of the flaring solar atmosphere from the two spacecraft. As a result (see Figure) ISEE-3 observed only X rays emanating from altitude (C–D) in the source greater than 25,000 km above the photosphere (A) while PVO observed all emissions (B–D) from above 700 km altitude. At burst peak the PVO flux above 50 keV photon energy exceeded the ISEE flux, extrapolated to the same energy range, by a factor of 600 and had a spectrum harder by about +2 in the power-law exponent. We can thus conclude that the hard X-ray source is concentrated at altitudes below 25,000 km, particularly at higher photon energies, with a factor of 600 above 50 keV. This result is a great advance on previous behind-the-limb results from single spacecraft which established the existence of a high altitude source component but gave no information on the differential height structure.

The importance of hard X-ray bursts lies not in the bremsstrahlung X rays themselves but in the energy of the electrons emitting them. These electrons represent a significant, and perhaps a large, fraction of the total energy released by magnetic field dissipation in a solar flare. How severe are the demands that this places on the electron acceleration process depends strongly on the hard X-ray source model assumed. In particular the acceleration efficiency involved is modest if the bulk of the source electrons are in a relaxed quasi-thermal state. On the other hand, if the source electrons are non-thermal they lose most of their energy by collisions to the cooler thermal plasma rather than to bremsstrahlung and a far greater total electron energy is required.



Schematic showing directions of the two spacecraft as seen from the Sun and the different heights in the X-ray source (hatched area) seen from each spacecraft.

Two possible cases of the latter situation are the descending electron beam (thick target) model (with acceleration near D in the Figure) and the trap model where fast electrons are confined in a magnetic arch after acceleration. Although these latter models pose problems for acceleration mechanisms, they provide a plausible interpretation of impulsive chromospheric emissions in flares in terms of electron bombardment. The greatest single source of ambiguity in modelling hard X-ray bursts to date has been the lack of spatial resolution.

There seems to be no ready interpretation of Kane *et al.*'s results in terms of the trap model since this predicts comparable X-ray fluxes from the trapped (coronal) electrons and those precipitating down the limbs to the chromosphere (unless by chance ISEE just glimpsed part of the arch summit at C). A thermal model just might fit the facts if quasi-thermal emission emanated from CD at energies up to around 50 keV while the high energy electron tail escaped downward. The most convincing interpretation at present, however, is the thick target model which predicts a difference of +2 in spectral index between coronal and chromospheric components, and much greater total flux at low altitudes (Brown & McClymont *Solar Phys.* **41,** 135; 1975). The PVO/ISEE flux ratio would then require an acceleration site D located at a plasma column depth of 2.5×10^{18} protons cm^{-2} above the 25,000 km level C. For quiet Sun conditions the plasma density n here is around 10^8 cm^{-2}, but such a low density could not sustain a stable reverse current to neutralise the descending beam. Reverse current stability demands $n \gtrsim 5 \times 10^9$ cm^{-3} which is consistent with the density enhancements typical of active regions. It will be of great interest to see whether a similar source distribution with height occurs in other bursts or if these are more consistent with one of the other source models.

In the coming months SMM will disgorge vastly more hard X-ray source spatial data than are contained in Kane *et al.*'s results. Specifically it will yield detailed information on horizontal source structure and so test whether electrons really do bombard the chromosphere. On the other hand the SMM telescope is limited to photon energies below 30 keV and, furthermore, has no spatial resolution along the line of sight. Thus the 'stereo' data of Kane *et al.* will remain unique until we are again fortunate enough to have two spacecraft and a flare in the right places at the right time. ☐

Tailoring liposome structure

from Gregory Gregoriadis

THE idea that drugs entrapped in lipid envelopes (liposomes) may provide a better means of delivery to specific sites within the body has aroused wide interest. Much of the interest in the liposomal carriers has no doubt stemmed from the almost unlimited number of potential versions in terms of composition, size and other characteristics. Indeed, correct choice of these parameters has, in some instances, led to liposomal preparations best suited for optimal drug action (for reviews of various aspects of liposomes see *Liposomes and their uses in Biology and Medicine* (D. Papahadjopoulos ed.) *Ann. N.Y. Acad. Sci.* **308,** 1978; *Liposomes in Biological Systems* (eds G. Gregoriadis & A.C. Allison) John Wiley and Sons Ltd, 1980). Recently, attempts have been made to rationalise liposome development by tailoring their structure to the particular biological milieu in which they are intended to act.

The ability to control the extent to which liposomes in the blood retain their entrapped drugs is obviously important to those interested in applying them systemically. Although in many cases drugs must be transported intact to where they are needed, in others their gradual release in the circulation may be preferable, especially when membrane barriers will prevent liposomes from reaching target sites.

In the blood, drugs are released from liposomes much more rapidly than expected from normal solute diffusion

through the bilayers (see reviews). This is attributed to the massive transfer of the liposomal component lecithin to the plasma high density lipoproteins (HDL) in turn leading to the loss of the carrier's integrity and ability to retain solutes (Krupp *et al. Biochem. biophys. Res. Commun.* **72**, 1251; 1976; Scherphof *et al. Biochim. biophys. Acta* **542**, 296; 1978; Chobanian *et al. Biochemistry* **18**, 180; 1979). It now seems that the plasma-induced structural damage to liposomes can be exploited to 'instruct' them either to retain entrapped drugs or release them at predetermined rates. Unilamellar or multilamellar liposomes can be made more stable in the circulation by incorporating cholesterol. Through modulation of phospholipid loss to plasma HDL (Kirby *et al., FEBS Lett.* **111**, 324; 1980), cholesterol controls bilayer permeability to solutes in the blood of injected animals in inverse proportion to its concentration (Gregoriadis & Davis *Biochem. biophys. Res. Commun.* **89**, 1287; 1979; Kirby *et al. Biochem. J.* **185**, 591; 1980). Sphingomyelin also has a similar effect *in vitro* (Finkelstein & Weissmann *Biochim. biophys. Acta* **587**, 202; 1979) although not necessarily by the same mechanism. Liposomes designed to retain their full drug load are expected to minimise the systemic toxicity of such drugs as the antimonials and metal chelators being tested in the intravenous treatment of experimental visceral leishmaniasis (Black *et al. Trans. Roy. Soc. Trop. Med. Hyg.* **71**, 550; 1977; New *et al. Nature* **272**, 55; 1978; Alving *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 2959; 1978) and iron loading (Guilmette *et al. Life Sci.* **22**, 313; 1978; Young *et al. Br. J. Haematol,* **41**, 357; 1979) respectively.

On the other hand, controlled release of drugs should promote their access to cells (tumours, for example) with which liposomes may not be able to interact directly (Rustum *et al. Cancer Res.* **39**, 1390; 1979). However, toxicity to normal tissues equally accessible to slowly diffusing drugs cannot be excluded. Therefore, for tissues which are amenable to hyperthermia, an alternative approach based on the property of liposomes to become leaky at the melting temperature of their phospholipid component (Yatvin *et al. Science* **202**, 1290; 1978; Scherphof *et al. Biochim. biophys. Acta* **556**, 196; 1979) may prove more useful. In this way, liposomal drugs delivered systemically can be released near and concentrate selectively in, appropriately preheated target areas such as tumours, infected or inflamed tissues (Weinstein *et al. Science* **204**, 188; 1979).

Whether systemic drug release or transport intact to target cells is required, the need for liposomes to persist in the blood for some time seems to rule out the use of the rapidly removed large liposomes (which may nonetheless be preferable for drug transport to the fixed macrophages or for capture in lung capillaries) and to favour the small unilamellar version. This, when uniformly sized, exhibits a linear rate of clearance and a half life which can be reduced as appropriate by the incroporation of negative charge.

Liposomes may also be introduced into the body other than through the circulation, and here the characteristics of the route of entry also influence the fate and efficiency of action of the liposomal drugs.

For instance, in arthritic rabbits injected intra-articularly with cortisol palmitate anchored on the lipid framework of liposomes, the degree and duration of the anti-inflammatory activity of the steroid is greatest in the initial acute phase of inflammation and is probably related to the phagocytic activity of the synovium (at later phases there are marked changes in its content of cell types) (Shaw *et al. Br. J. exp. Path.* **60**, 142; 1979). Interestingly, a similar beneficial effect of the liposomal steroid has been demonstrated in a few patients with rheumatoid arthritis (de Silva *et al. Lancet* **i**, 1320; 1979).

In another topical use potentially applicable to the chemotherapy of pulmonary metastases, an anti-tumour agent entrapped in positively charged liposomes and administered through the intratracheal route acted in the lung without adverse side effects in other tissues (McCullough & Juliano *J. natn. Cancer Inst.* **63**, 727; 1979).

After injection into tissue (which is of a wider therapeutic scope), liposomes can either disintegrate locally or migrate into the lymph nodes draining the injected tissue (Segal *et al. Clin. Sci. molec. Med.* **49**, 99; 1975). It has now been shown (Osborne *et al. Int. J. Nucl. Med. Biol.* **6**, 75; 1979) that localisation in the primary and secondary regional lymph nodes is enhanced dramatically when small uncharged liposomes are used. In addition to its obvious usefulness in the detection and treatment of tumours of the lymphatic system lymph node localisation of liposomes may also be the cause of their immunopotentiating property (Allison & Gregoriadis *Nature* **252**, 252; 1974; Morein *et al. Nature* **276**, 715; 1978; van Rooijen & van Nieuwmegen *Immun. Commun.* **8**, 381; 1979). This immunopotentiating effect has already shown promise in vaccine development (for example in conjunction with hepatitis B virus surface antigen for a vaccine against hepatitis, Manesis *et al. FEBS Lett.* **102**, 107; 1979).

It has become apparent that ways of controlling the fate of locally applied liposomes can extend beyond simple manipulation of their size and charge. A related development is the finding (Mauk *et al. Science* **207**, 309; 1980) that the rate of disintegration of liposomes in injected tissues can be varied widely by the incorporation of various sugars and amino sugar derivatives of cholesterol into the lipid structure. These derivatives seem to mediate binding of the associated carrier to the intercellular or cell surface components which, in turn, controls its endocytosis. Such modifications could prove useful in cases where interaction of liposomes with and uptake by cells (for example, gut cells after oral administration) is at present poor or non-existent. □

Io: the electrified satellite

from Garry E. Hunt

OF the 14 Jovian satellites, Io, one of the four planet-sized Galilean moons, presents the greatest anomaly, not only of the Galilean satellites but also among all the other bodies in the Solar System. During the recent Voyager encounters spectacular eruptions were seen on Io which have been initially interpreted as evidence for extensive volcanic activity (Smith *et al. Science* **204**, 951; 1979; Smith *et al. Science* **206**, 927; 1979). But is this the only possible interpretation? Gold (*Science* **206**, 1071; 1979) suggests an alternative explanation of these dramatic observations. He suggests that the passage of Io through the powerful magnetic field of Jupiter induces electric currents in Io's crust which heat up areas of the surface and cause the ejection of volcanic-like plumes of gaseous and solid material. Is this hypothesis possible?

There is no doubt that the eruptions on Io were probably the least expected, and most exciting, results of the Voyager mission. Certainly before the mission, the generally accepted view was that the surface of Io would be heavily cratered rather like the Moon. However Peale *et al.* (*Science* **203**, 892; 1979) had pointed out that since Io is subjected to resonant gravitational forces exerted by its sister moon Europa, its orbit would be distorted from its approximately circular path. Consequently, Io would be affected also by Jupiter's powerful gravitational field so that this repeated tidal flexing would create an enormous amount of frictional heat in the satellite's interior. This heat would ultimately have to be dissipated through the surface of Io. Would this necessarily result in widespread volcanism?

Smith *et al.* (*op. cit.*) observed eight active plumes on the first Voyager encounter, of which six were still active at the time of the second flyby three months later. In both cases, material was seen to reach altitudes of 70-280 km at ballistic speeds of up to 1 km s^{-1} (Cook *et al. Nature* **280**, 743; 1979). Interestingly, all except one of these plumes lie within ±30° of the equator (Strom *et al. Nature* **280**, 733; 1979). The eruption sites appear as regions with a central dark or black irregular to

Garry Hunt is the director of the Laboratory for Planetary Atmospheres, Department of Physics and Astronomy, University College London.

0028-0836/80/09815-02$01.00

circular spot that generally appears to have radiating dark, jet-like streaks. In many ways, the vents mapped from the Voyager imaging data appear to resemble closely terrestrial calderas or pit craters (Masursky *et al. Nature* **280**, 725; 1979). The floors of these features range from externally shallow to about 4 km in depth. However at least 300 caldera-like features have been detected randomly distributed over Io's surface and not therefore controlled by strongly patterned convection cells.

The south polar region is certainly important in these discussions. McCauley *et al.* (*Nature* **280**, 736; 1979) have observed white or bluish patches along scarps and faults, particularly in this region. Such features are diffuse, sometimes variable and obscuring the surface, suggesting that they may be cloud produced by gas leaking out of the interior of the satellite and condensing into some form of snow. Certainly, Pearl *et al.* (*Nature* **280**, 755; 1979) have detected a tenuous atmosphere of sulphur dioxide, while several observers (Fanale *et al. Nature* **280**, 761; 1979; Nash & Nelson *Nature* **280**, 763; 1979; and Smythe *et al. Nature* **280**, 766; 1979) indicate the presence of this material on the surface of Io. The surface is then probably a mixture of sulphur and sulphur dioxide. So there may be reservoirs of liquid sulphur dioxide on Io analogous to the lakes and oceans of the Earth. How therefore can we account for the plume features?

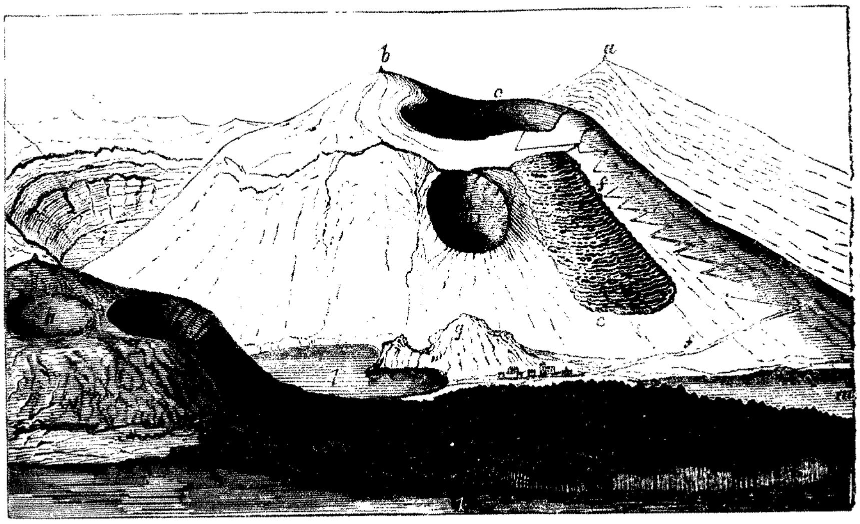
In certain locations, the observations suggest that ice clouds are issuing from fractures in Io's crust, and there is no doubt that liquid sulphur dioxide would escape to the surface along a fault or at the base of a scarp. Certainly, as it reaches the surface the sudden reduction in pressure to below the critical point would cause the liquid to explode into an ice fog that would spread out and then ultimately fall back to the surface again. The process may also erode material along the scarps as well, as McCauley *et al.* (*op. cit.*) suggest. Could this procedure account for the larger plumes that have been observed?

Smith *et al.* (*op. cit.*) suggest that this is the case, with the liquid sulphur dioxide causing violent reactions. This model requires large segregated pools of sulphur below the satellite's surface, and there are certainly some volcanic-like flows that may be of pure sulphur as Sagan (*Nature* **280**, 750; 1979) suggests.

However, an alternative view is taken by Carr *et al.* (*Nature* **280**, 729; 1979) who suggest that the volcanism is not primarily driven by the tidal forces, but by a mechanism in which the sulphur-enriched silicate magma erupts through a silicate crust enriched in sulphur. The variations in the physics and chemistry of the magma chambers may then account for the different types of eruption and therefore the different features on Io. Certainly it is difficult to imagine that volcanism on Io has continued at the same rate throughout the history which is implied by the tidal heating model. The other volcanic bodies, Mars, Venus, Moon and Earth, have certainly had variable periods of volcanism. So why should Io be different?

Gold (*op. cit.*) however, suggests that all these geologically-based interpretations are unsatisfactory. While there is no disputing the altitude and speed of the material in these plumes, he suggests that such behaviour is unlikely for sulphur compounds under volcanic conditions. He indicates that for such material to reach the observed speed of up to 1 km s^{-1}, it would have to be heated to about 6,000 K. Certainly the temperatures that can be expected in any volcanic region are likely to be below 1,500 K for nearly all rock-forming minerals. Furthermore, volcanic activity is supposedly more extensive on Io than on the Earth, so that the internal heating of Io would therefore be greater. But Gold calculates an Ionian heat flow of only 46 erg cm^{-2} s^{-1} from the data of Peale *et al* (*op. cit.*) compared with 65 erg cm^{-2} s^{-1} for the Earth.

With these inconsistencies, further examination of the Io eruptions is required. Gold points out that the satellite resides in the intense Jovian magnetosphere so that it will be electrically heated. Certainly Io, with a density of 3.5 g cm^{-3}, is composed of materials that conduct electricity and currents will flow through it as the satellite moves through the Jovian magnetic field. If this electric arc interpretation is correct, then the outbursts would repeat in a systematic way, controlled by the repetition cycle of the external field configuration. Local hot spots would be created, which is consistent with the observations by Hanel *et al.* (*Science* **204**, 972; 1979). The strong concentration of the majority of the plumes around the equatorial region indicates that this mechanism is appropriate in that region. However, in other locations, such as those of the poles, sulphur dioxide venting may be more appropriate. The eruption characteristics of Io may therefore be a complex mixture of volcanism and the results of the special electrical environment in which the satellite resides. Whatever the explanation there is little doubt that Io is in a hyperactive state, with the youngest surface currently known in the Solar System. □



100 years ago

Lipari is about ten and a half square miles in area. The highest point is 1,978 feet above the sea. Everywhere the island betrays its volcanic origin. Tuff, pumice, liparite (quartz-trachyte), and obsidian, are constantly met with; at San Calogero a hot spring (198°F.) pours forth water charged with carbonic acid and sulphuretted hydrogen, while the Bagno Secco discharges steam, sulphurous acid, and (it is said, but I think the statement requires confirmation) hydrochloric acid.

Vulcano is undoubtedly the most interesting member of the group from a volcanic point of view. It lies between four and five miles to the south of Lipari, and contains a semi-active crater, which, as regards its usual dynamic activity, occupies a mean position between Vesuvius in its present state of action, and an actual solfatara like that of Puzzuoli. Sulphur, alum, and boracic acid are the substances procured from the crater. We noticed also sublimates of sulphide of arsenic, and salts of copper were found in association with some of the aluminous incrustation; also chloride of ammonium. I have been assured by two eye-witnesses that blue and green flames sometimes issue from clefts in the bottom of the crater.

Prof. A. Cossa (*Gazetta Chimica Italiana*, 1878, p. 235-246) has pointed out that Vulcano furnishes the richest supply known of caesium and rubidium. The Faraglioni, also called *rocca dell' alume*, is a trachytic mass much decomposed by sulphurous and sulphuric acids; potassium-alum is found in its cavities, associated with the sulphates of aluminium and calcium, with chloride of ammonium, and with the alums of thallium, caesium, and rubidium. The most complex mixture of volcanic products hitherto found was discovered by Cossa on the edges of a small fumerole at the bottom of the crater of Vulcano. It was found to consist of the sulphides of arsenic and selenium, chloride of ammonium, boracic acid, sulphate of lithium, together with caesium- and thallium-alums, and traces of the alums of potassium and rubidium. REVIEW ARTICLE

Nuclear weapons and power-reactor plutonium

Amory B. Lovins

Consultant Physicist, c/o Friends of the Earth Ltd, 9 Poland Street, London W1V 3DG, UK

With modest design sophistication, high-burn-up plutonium from power reactors can produce powerful and predictable nuclear explosions. There is no way to 'denature' plutonium. Power reactors are not implausible but rather attractive as military production reactors. Current promotion of quasi-civilian nuclear facilities rests, dangerously, on contrary assumptions.

NUCLEAR policy, especially in Europe, has often been justified by the belief[1-10] that for making nuclear bombs, 'reactor-grade' plutonium produced by the normal operation of uranium-fuelled power reactors is necessarily much inferior to specially made 'weapons-grade' Pu: so inferior in explosive power or predictability that its potential use by amateurs is not a serious problem and that governments would instead make the higher-performance weapons-grade Pu in special production reactors.

Although that belief is false it was vigorously asserted during 1978–79 by responsible Ministers or by Prime Ministers in at least three high-technology nations. This was apparently because some of their nuclear experts did not know differently, and rejected contrary official US statements as being exaggerated or even politically motivated; or because those experts who did know were not asked; or because correct technical advice was lost, oversimplified, or garbled in transmission through advisors who did not understand the physics. Here I attempt to clarify the properties and performance of various grades of Pu, outlining the physical logic explicitly enough to ensure understanding although discreetly so as not to help the malicious: certain details and technical references have, therefore, been omitted and some calculations treated in conclusory fashion.

The possible military utility of power-reactor Pu has caused widespread professional confusion since 1946. Although some leading scientists appreciated even then[1,11] that it was useable in bombs or might become so, the contrary assumption (admittedly hedged) was made in the Acheson-Lilienthal report[12,13]. This recommended that certain nuclear activities could be classified as 'safe' because the Pu they produced could not be converted without timely warning into weapons-useable form, and that these activities could thus be carried out by nations if under strict and enforceable international controls. With the radical 1953 Atoms for Peace initiative, the report's finding that international inspections and treaties could not stop proliferation was forgotten, and US nuclear knowledge and materials were distributed worldwide with increasing enthusiasm and decreasing care[14]—apparently on the assumption that power-reactor Pu was, or could be made, unsuitable for use in bombs ('denatured'), despite the US Atomic Energy Commission's refutation of this notion[15] in 1952. With this in many signatories' minds, the Non-Proliferation Treaty (NPT) was negotiated in 1967: an important fact to recall when construing the NPT today, even though its text and the International Atomic Energy Agency (IAEA) do not distinguish in quality between Pu made in power or in military production reactors.

Beginning publicly in the early 1970s in the US (earlier in the Soviet Union and France[16]), the assumption that power-reactor Pu was unsuitable for bombs was questioned with increasing force[17,18]. By 1974, authoritative reports[19,20] had concluded that reactor-grade Pu could be used even by amateurs to make effective fission bombs, albeit of somewhat reduced and uncertain yield[21-25]. Further analyses during 1976–77, mainly at the US weapons laboratories, revealed a still wider spectrum of technical possibilities, and in 1977 the US announced that it had successfully tested a bomb made from reactor-grade Pu[26,27]. Yet the earlier finding that this material, though useable, was inferior if used in relatively crude bomb designs was widely and wrongly supposed to apply to all designs. In particular, reactor-grade Pu was alleged to be inherently:

—far more hazardous than weapons-grade Pu to people dealing with it; or

—far more likely to cause unintentional explosions; or

—incapable of exploding violently enough to do much damage, or, at worst, to accomplish most military aims; or

—too unpredictable in explosive yield to be acceptable to its users.

Each of these assumptions contains, in certain circumstances, some truth; but each is generally, or can by plausible countermeasures be rendered, false. Their implication that reactor-grade Pu is not very dangerous, or unlikely to be attractive to governments, is wishful thinking, and causes the proliferation risks of 'civil' nuclear activities to be gravely underestimated.

In recent years, advocates of commercial Pu use, in referring to the bomb-making that might also result, have had to retreat "from the original concept of denaturing to the notion of making do with less than optimal material"[11]; yet the earlier myth lingeringly distorts policy[28]. To decide responsibly about nuclear power and nuclear fuel reprocessing, we must know exactly what "less than optimal" means, and hence must cautiously review published physical principles. The only thing more dangerous than discussing this subject is not discussing it; the lesson of Atoms for Peace may yet be that with Pu, we must get our assessments right the first time.

Plutonium production

All nuclear reactors fuelled with uranium[29] (notably the 0.7%-naturally-abundant species ^{235}U) produce ^{239}Pu by neutron absorption in fertile ^{238}U. Some of the ^{239}Pu formed is fissioned; an increasing fraction absorbs successively more neutrons to form higher Pu isotopes, chiefly $^{240-242}$Pu, and transplutonic elements[30]; and some of the resulting $^{239-242}$Pu (plus traces of ^{238}Pu and related species) survives until the fuel is discharged. Depending[19,24,25] on the type and detailed design of reactor, the composition of initial fuel, and the manner of operation, especially the burn-up (extent of exposure of the fuel to neutrons), the net Pu production of a 1-GWe power reactor is typically several hundred kg yr^{-1}, for example ~210–240 kg yr^{-1} for a light-water reactor (LWR), the dominant commercial type.

0028-0836/80/090817—07$01.00

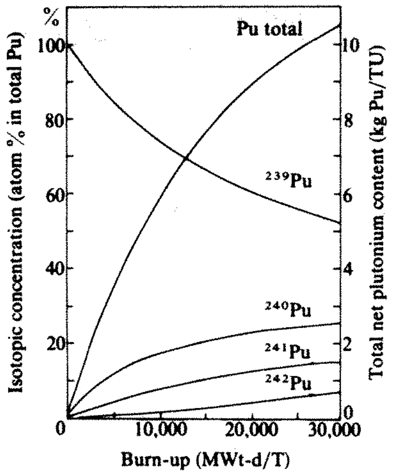

Fig. 1 Typical total amount and isotopic composition of plutonium in discharged fuel as a function of burn-up in a light-water reactor[32]. The exact values depend in detail on reactor design and operation and on initial fuel composition. Higher isotopes of plutonium and transplutonics become more abundant in repeatedly recycled fuel.

For a given reactor, the isotopic composition of the discharged Pu depends predictably on burn-up. If each metric ton of uranium (TU) yields only a few gigawatt-days' thermal energy (GWt-dT), neutron capture is so limited that nearly pure ^{239}Pu—'weapons-grade' Pu—is produced. It contains no more[1] than 7%[24] or 8%[11] ^{240}Pu, typically[31] around 6%; perhaps 0.5% ^{241}Pu; negligible ^{242}Pu and ^{238}Pu.

Higher burn-up, whether through leaving the fuel in the reactor longer or exposing it to a more intense neutron flux, produces a larger proportion of the higher Pu isotopes (Fig. 1). Low-enriched uranium fuel (the usual kind) left for the full 3–4 yr in a reliably operating LWR is usually designed for a nominal burn-up of 27–33 GWt-dT. The latter corresponds[33] to discharge Pu containing ~58% ^{239} Pu and 11% ^{241}Pu (both fissile) plus 25% ^{240}Pu, 4% ^{242}Pu, and 2% ^{238}Pu. This composition is broadly similar for other thermal or fast reactor types, except for graphite-moderated reactors[34] ($^{240+242}$Pu ~ 20%) and fast breeder radial blankets[30] (~ 4%). In some circumstances the $^{240+242}$Pu fraction can rise from a nominal ~29% to as much as 49% (34% ^{240}Pu, 15% ^{242}Pu)[33] in equilibrium LWR Pu recycle fuel; this is unusually high and approximates a practical limit.

Power reactors also can, and often do, discharge fuel short of its full design burn-up. Mature US LWR cores routinely attain well below design burn-up[35]. Real or simulated malfunctions, such as leaky fuel cladding, may lead the operator to discharge fuel at very low burn-up[1]. Alternatively, manipulation of fuel rods can produce a core with high average burn-up but containing some rods of much lower burn-up. 'On-load-refuelling' reactors such as Magnox and CANDU are suitable for clandestine introduction, brief exposure, and removal of small but adequate amounts of fertile material in a few fuel channels. Such methods are not necessarily easy to detect even if an inspector were continuously present, and would probably not be detected at all by present international safeguards[36].

Because burn-up, and hence isotopic composition of discharge Pu, can vary enormously between and within reactors and with time, 'reactor-grade Pu' is not a well-defined term. Weapons-grade Pu, which is fairly well-defined (supra), can be readily produced in any power reactor without necessarily and significantly decreasing efficiency, increasing costs, or being detected. But though that option is always open, we assume here that it is not—that power reactors will be used to produce only high-burn-up Pu. We also assume that 'reactor-grade Pu' implies a $^{240+242}$Pu content of ~30%; higher, even arbitrarily higher, even-isotope content will not affect the argument, while a lower content would strengthen it. On these conservative assumptions, the Pu discharged from power reactors will be shown to have major military potential.

Plutonium properties

Relevant nuclear properties of the common Pu isotopes are summarised in Table 1. The values given for m_c are not the quantities needed to make a bomb, as neutron reflection and implosion can reduce critical mass by a large factor. This factor has been officially stated to be ~ 5, consistent with the US[39] and IAEA requirement of strict physical security measures for quantities of Pu $\geqslant$ 2 kg (independent of isotopic composition). Published data suggest, however, that with sophisticated design the factor may be > 5. For example, in its densest (α-phase) allotropic form, ^{239}Pu at normal density in a thick Be reflector has a reported critical mass as small as $m_c/4$, and large reflector savings are also obtainable with nonmoderating (and partly fast-fissionable) reflectors such as ^{238}U. Further, if the core and reflector are equally compressible and if the ratio of reflector thickness to core radius remains constant during compression, critical mass varies as the inverse square of core density. Densities 'several times' normal are said to be attained in military

Table 1 Some properties of plutonium[31,34,37,38]

Isotope	Decay properties: Half life (yr)	Decay properties: Main emission (MeV)	Specific activity (Ci g^{-1})	Heat (W kg^{-1})	Fast-fission: m_c* (kg)	Fast-fission: $\bar{\nu}$†	Fast-fission: σ_f‡ (barn)	Spontaneous fission: Rate (n g^{-1} s^{-1})	Spontaneous fission: $\bar{\nu}_{SF}$§

* Approximate bare-sphere prompt-critical mass at normal density; Pu is α-phase ($\rho = 19.8$ g cm^{-3}). For comparison, m_c for 93.5% ^{235}U ($\rho = 18.8$ g cm^{-3}) is 49 kg ^{235}U.

† Approximate gross neutron yield per fast fission (Argonne 16-group).

‡ Approximate fast-fission cross-section (Argonne 16-group). (The capture-to-fission ratios are also important, and tend to be high for even Pu isotopes.)

§ Approximate neutron yield per spontaneous fission.

‖ Values cited by De Volpi[37], who gives the ^{238}Pu m_c as 7 kg (unpublished); the best value calculated for α-phase, however, is the $m_c \sim 9.2$ kg shown here (R. W. Selden, personal communication).

¶ Best Livermore estimate from the range 75–100 kg (R. W. Selden, personal communication). De Volpi[37] assumes ~95 kg (or 118 kg in Appendix H), but used $\geqslant$156 kg in earlier publications[45,46]. Calculated m_c is probably not finite for ^{242}Pu^{10}B$_2$, owing to threshold effects, but is ~350 kg for ^{240}Pu^{10}B$_2$ at $\rho = 11.5$ g cm^{-3} (R. W. Selden, personal communication).

# Daughter of ^{241}Pu, important (like the trace isotope ^{236}Pu) mainly for its γ emissions.

** Approximate estimate by Clayton[38] for $\rho = 11.7$ g cm^{-3}, implying reactivity comparable with ^{240}Pu.

bombs[40], and by means described in the open literature a slightly subcritical mass of α-phase ^{239}Pu in a U reflector can be compressed to 1.85 times its initial density, corresponding to a reactivity increase of ~3.4 times. The same method can yield even higher compressions. Although high compression is inconsistent with simultaneous high reflection, it may be possible to achieve significant supercriticality with initial ^{239}Pu masses under 2 kg. Regardless of the exact figure, the IAEA's 8-kg 'significant quantity' design basis for detecting diversions[36] seems far too high.

Of the Pu isotopes in Table 1, only ^{239}Pu and ^{241}Pu are fissile, that is, fissionable by thermal (slow) neutrons. All Pu isotopes, however, are fissionable by the fast neutrons in a bomb: indeed, at energies > 1 MeV (69% of fission neutrons) the fission cross-section of ^{240}Pu is less than that of ^{239}Pu by a margin of less than 20%, so the amount of ^{239}Pu required to form a normal-density critical mass is remarkably insensitive to $^{240+242}$Pu content (Table 2). Published neutron transport calculations confirm that the even isotopes produce only minor changes in reactivity, neutron spectrum, and mean prompt-neutron lifetime. So reactive is ^{240}Pu that changing the $^{240+242}$Pu content from 6 to 30% increases m_c only from ~11 to ~13 kg[31]. No known fast-neutron absorber can make Pu of any practical composition incapable of forming a prompt-critical mass[31,42]: calculations[42] suggest that substituting the best fast-neutron absorber known, ^{10}B, for oxygen in reactor-grade crystal-density PuO_2 ($m_c \sim$ 35 kg) would increase m_c only to ~70 kg.

Fast-fission properties of Pu, then, are only slightly affected by ordinary changes in isotopic composition. The neutron background is, however, modestly affected. Spontaneous-fission neutrons (Table 1) provide typically[34] of the order of 100 n g^{-1} s^{-1} in weapons-grade Pu, about 500 in reactor-grade Pu. A further contribution (at lower neutron energies) comes from (α, n) reactions with light-element impurities. In Pu metal this is not an important neutron source[34], but it can more than double the neutron background in PuO_2, as 1 Ci of α-emitter bombarding oxygen produces of the order of 5,000 n s^{-1}.

Neutron background from all sources is significant for weapons physics (infra) and makes reactor-grade Pu give somewhat higher radiation doses than weapons-grade Pu. For long-term commercial handling within the normal canons of health physics, shielding would be required. For clandestine weapons manufacture it would not, because the published total dose rates (mainly γ and X rays) are relatively modest—of the order of rem h^{-1} at the surface of a 1-kg fresh recycled PuO_2 sphere, < 1 mrem h^{-1} at 1 m. Even under extreme assumptions (18½% ^{238}Pu, 30% $^{240+242}$Pu, 10-kg PuO_2 sphere with subcritical multiplication included), neutron dose rates (60 mrem h^{-1} at 1 m) "do not provide an effective deterrent"[44]. It is obviously not correct that "slight mistakes in the knowledge of exact [isotopic] composition .... may well pose extreme radiological hazards"[43], given normal precautions against inadvertent criticality.

The specific activity of reactor-grade Pu is typically[42] ~10 Ci g^{-1} as against 3 Ci g^{-1} for weapons-grade Pu, the neutron background (for metal) and the inhalation toxicity ~5 times higher, and the heat production ~10 W kg^{-1} (about the same as for 1-yr-old spent LWR fuel) as against 3 W kg^{-1}. Only a difference of orders of magnitude in these quantities—the extent by which they all exceed the corresponding values for ^{235}U—would reflect differences in ease of handling that would be important in designing new bomb-making facilities[42].

'Thermal denaturing'[44–46] of reactor-grade Pu was recently proposed by A. K. Williams *et al.* (unpublished Allied-General Nuclear Services) and A. De Volpi[37]. The ^{238}Pu content would be increased from its normal 1–2% (nearly 5% in some recycle Pu[33]) to 10–15%, perhaps nearly 20%, chiefly by recycling ^{237}Np (itself a bomb material with $m_c \sim$ 75–105 kg) with ^{232}Th rather than ^{238}U diluent[29]. The ^{238}Pu would increase heat production to 6–9 times normal. Some calculations[44] based on cores of high mass and high volume-to-surface ratio, in direct contact with non-thermally-stable explosives, suggest serious design problems. But realistic choices of geometry and materials can readily overcome these problems. Cooling does not even become an interesting design problem until the ^{238}Pu content approaches that of a thermoelectric heat source, and a much lower content, well over 20%, does not provide an effective deterrent even to most amateurs, though it would make safe and economic fuel-cycle operations hard to envisage[47]. Only in quite incompetent hands could the extra heat pose a danger of unplanned detonation.

Table 2 Critical mass of plutonium spheres in a ~10-cm natural uranium reflector as a function of plutonium isotopic composition[41]*.

$^{240+242}$Pu (atom %)	^{239}Pu in critical mass (kg)	Total Pu in critical mass (kg)
0	4.4	4.4
10	4.5	5.0
20	4.5	5.6
30	4.6	6.7
40	4.7	7.8
50	4.8	9.6

* Assuming ^{240}Pu/^{242}Pu ratio similar to that shown in Fig. 1.

A second 'denaturing' proposal by De Volpi[37] would combine ^{238}Pu and ^{240}Pu with extra ^{242}Pu, which is a diluent in fast spectra and something of a neutron poison in thermal spectra[48]. Pathologically high ^{242}Pu content would increase m_c, though not by the ~30 times claimed by Olds[45] (compare Table 1); as all Pu isotopes have "reasonably small critical masses, this concept [of denaturing by dilution] is not applicable to plutonium"[44]. De Volpi states[46] that fuels made mostly of ^{242}Pu and with a fissile fraction as low as 18% are useable even in present fast reactors, but he does not analyse performance or economics, which apparently offer serious difficulties[48], and his analysis of weapons physics seems deeply flawed.

Synergisms are negligible, so the effect of each even Pu isotope can be dealt with separately: thermal 'denaturing' with ^{238}Pu above and neutronic 'denaturing' with all three isotopes below. Practicable dilution with ^{242}Pu cannot alter design constraints enough to affect the conclusions below.

Finally, nonmetallic forms of Pu must be considered. Reactor-grade Pu can be used directly in bombs without reduction to metal (though metal generally gives better performance). The oxygen in PuO_2 dilutes the Pu and lengthens the 'generation time' between fissions, reducing the yield, but it also slightly compensates by moderating the neutrons to lower energies where the fission cross-sections are higher. The dilution effect predominates and roughly doubles[42] the δ-phase metallic m_c. It also alters other design parameters. Nonetheless, the oxygen is not a neutron poison and does not prevent attainment of "large reactivity coefficients and short neutron life times"[18] even in the much less reactive $^{235}UO_2$. Indeed, the low initial density ($\rho \sim$ 2.3 g cm^{-3} uncompacted, 4–5 g cm^{-3} moderately compacted) of PuO_2 powder relative to its sintered ($\leqslant$ 11.2) or crystal (11.5) density, and its relative compressibility at crystal density, permit crude designs with a generous safety margin of initial subcriticality to achieve high supercriticality after implosion. It is, therefore, not surprising that PuO_2 has been uniformly agreed to be directly useable in formidable explosives[18,19,24,25,41]. A bomb made directly even from fresh LMFBR mixed-oxide fuel (15–25% Pu) is theoretically possible[49], though unwieldy.

Weapons physics and reactor-grade plutonium

A nuclear explosion results from a divergent chain reaction in a prompt-supercritical mass: that is, one which can support a chain reaction by virtue only of the prompt neutrons released immediately by fission. The fission neutrons in a bomb are fast, with energies in the megavolt range and velocities of the order of 1–2 × 10^9 cm s^{-1}. The fissionable material must be of sufficient size and density that a neutron born within it is likely to cause a further fission within it. The critical masses discussed above imply that the mean distance between fissions is of the order of centimetres, hence that the mean time between fissions is of the order of 10^{-8} s. Roughly "40–50 generations of fissions are required to build up a fast chain reaction to an explosive level"[41]: $e^{40} = 2.4 \times 10^{17}$ fissions would release 1.6×10^3 kcal, equal to the nominal energy release from ~1.6 kg of high explosive and thus approaching the energy density needed to disassemble rapidly a Pu core of nominal size. Only the last few generations in this exponential process provide appreciable energy yield. That energy builds up, in a few hundredths of a microsecond, temperatures of several hundred million °C and pressures of the order of 10^8 bar, causing the core to expand with a velocity of the order of 10^8 cm s^{-1}. Expansion from the initial radius by a factor roughly equal to the sixth root of the number of critical masses present, that is, by ~1 cm, makes the mass subcritical and quenches the chain reaction. Once the explosion begins, then, only a few more generations of fission, producing most of the yield, are possible.

The designer seeks to assemble as supercritical a mass as possible (by 'inserting reactivity') as quickly as possible, and to inject neutrons to initiate the chain reaction at the optimal moment during that assembly—before the instant of maximum supercriticality, so that the bomb's tendency to fly apart is partly countered by the continuing forces of convergent assembly. The yield of the nuclear explosion depends strongly on the degree of supercriticality achieved when the chain reaction is initiated. If the neutron background is so large that preinitiation, before the optimal moment, is likely, then the yield varies[18] as (rate of reactivity insertion)$^{-1-1.5}$.

Preinitiation reduces yield according to the Poisson statistics of neutron background, and can be counteracted by faster assembly. For a constant level of maximum reactivity insertion, the probability of avoiding preinitiation varies as 1/exp (neutron source strength × assembly time).

Preinitiation is a problem faced by any nuclear weapons designer using any fissionable material[31]. With ^{235}U (spontaneous fission rate 8×10^{-4} n g^{-1} s^{-1}), it is a mild problem, so assembly by the relatively slow 'gun' method at published rates <1 mm μs^{-1} (0.3 mm μs^{-1} in the Hiroshima bomb) suffices. But even weapons-grade Pu, with neutron background ≥60,000 times higher (just above ^{238}U), preinitiates unless assembled implosively by a convergent arrangement of chemical high explosives. The radial compression rate can then[32] exceed 2 mm μs^{-1}.

A reflected core of Pu metal, sufficiently subcritical that neutron multiplication can be neglected, will have a neutron background of the order of 0.5×10^6 n s^{-1} if of weapons grade, several million n s^{-1} if of reactor grade. The former figure implies a mean time between neutrons of a few microseconds—half an order of magnitude longer than the duration of the fission chain. But the latter figure implies a mean time between neutrons that is short compared with the time required to complete the assembly of a highly supercritical mass, unless that assembly is extremely rapid, implying very high shock velocities and compression. This can in fact be achieved:

> "Plutonium of any feasible grade (weapons or reactor) is unsuitable for the gun-assembled systems because the neutron background and relatively long assembly time introduces significant preinitiation probabilities. This is not necessarily true for implosion types"[34].

Preinitiation, then,

> "... does *not* necessarily make an explosive unreliable. Preinitiation *does* result in a statistical uncertainty in the yield ... [that] is statistically distributed between predictable upper and lower limits which are likely to be more than a factor of 10 apart. For a *well-understood design properly constructed*, however, the most probable yield range could be predicted within much closer limits"[24].
>
> "In implosion devices, preinitiation probabilities may be lowered by various design techniques. Even relatively low technology designs, notwithstanding the variability in yield, *can produce effective, highly powerful weapons*"[34].

This can be achieved[41] even with a neutron source strength of the order of 10^6 n s^{-1}. As was officially appreciated in 1944,

> "... [A] rough quantitative analysis of the assembly velocities attainable with very large charges of high explosive ... suggested that because of the strong focusing effect of the converging material, one could introduce a strong steady source of neutrons into the bomb (for example, by deliberately leaving the material in an impure state), and still beat the chain reaction and attain complete assembly".

Thus preinitiation "... *may mean a statistical uncertainty in the yield within a predictable range.* Increasing technological sophistication will reduce this uncertainty"[31].

Now, consider several several levels of "increasing technological sophistication" and their likely effects on the performance of implosion bombs made from reactor-grade Pu or other compositions[37] with high neutron source strength.

Performance as a function of design

Since it became public knowledge that construction of illicit nuclear weapons by non-state adversaries must be taken seriously[19], and that reactor-grade Pu is suitable for such bombs[17,18,24], the level of technology on which most discussions have centred can be described as 'crude amateur designs' in which the normal military design requirements for pure fissile material and for the symmetry, simultaneity, and speed of implosion are very considerably relaxed. The canonical description of such designs is that of Willrich and Taylor[19]:

> "Under conceivable circumstances, a few persons, possibly even one person working alone, who possessed ~10 kg of plutonium oxide and a substantial amount of chemical high explosive could, within several weeks [or perhaps less], design and build a crude fission bomb... [that] would have an excellent chance of exploding, ... probably ... with the power of at least 100 tons of chemical high explosives. This could be done using materials and equipment that could be purchased at a hardware store and from commercial suppliers of scientific equipment for student laboratories.... [It] might yield as much as 20 kilotons of explosive power—the equal of the Nagasaki A-bomb [though the probability of such a high yield is quite small]."

"... very sophisticated thermal-hydraulic and neutronic calculations"[43] would not be needed. Several suitably comprehensive literature searches have in fact been conducted by amateurs. The bomb could fit in a car[41].

Making an effective, transportable fission bomb is not a trivial task. Safely realising a paper design in properly working apparatus would require alertness to subtleties and care and skill in technical arts (which many criminal enterprises have shown). The necessary human resources will be assumed here to have been obtained. The skills required for both design and fabrication naturally increase with increasing sophistication and have been taken into account in the policy conclusions drawn here.

Several studies[32,43,50,51] have dealt quantitatively with the heterogeneous class of flexible and imprecise designs grouped here as Level One technology. Calculations confirm that in the absence of gross incompetence or malfunction of major components, Level One technology is extremely likely to yield >0.01 kton, likely to yield in the range 0.1–1 kton, able on occasion to yield several kton, and unlikely to yield 10–20 kton.

A second level of technology might be characterised as 'imitation Trinity designs' or as 1945-vintage US technology. It uses special high-explosive components and detonators (all of which are commercially available) in a straightforward geometry to compress an accurately made metallic Pu core. Given the materials and information that have become widely available since the 1940s, such a technology might be typical of a low-level national effort to produce a bomb that can be depended on to work well without previous testing (Trinity yielded 17 kton). It is not a clever technology (simpler means can produce better results) but is basic and reliable, and has been the subject of several amateur design exercises. Five distinguished nuclear weapons experts concluded that using weapons-grade Pu (or ^{233}U or highly enriched ^{235}U)

> "... it is possible to design low-technology devices that would reliably produce explosive yields up to the equivalent of 10 or 20 kilotonne of TNT. With reactor-grade plutonium it is possible to design low-technology devices with probable yields 3–10 times lower than those mentioned above (depending on the design), but yields in the kiloton range could be accomplished. Militarily useful weapons with *reliable* nuclear yields in the kiloton range can therefore be constructed using low technology and reactor-grade plutonium"[24].

(This is consistent with De Volpi's Table L–6 results[37], given realistic choices of parameters.) As for the resources required, "a small group of people, none of whom have ever had access to the classified literature", could get by with "modest machine-shop facilities that could be contracted for without arousing suspicion" and with "a fraction" (perhaps a small fraction) of a million dollars for open-market equipment[24].

Recently declassified documents dealing with 1945 US technology give[1]

> "... quite precise quantitative information ... covering some aspects of how the probability distribution of nuclear yields changes with the isotopic composition of the plutonium used. ... This information makes clear that with power reactor grade plutonium, an implosion weapon of even the simple kind first used by the US would reliably have yields between 1 and 20 kton"[52].

Preinitiation at the least favourable moment[50] in a Trinity-type bomb would still produce[1] reliable kiloton yields: the worst-case, minimum, 'fizzle' yield is still a "militarily useful"[31] ~1 kton. This behaviour is chiefly a function of assembly rate, not neutron background, because the least favourable moment cannot get any less favourable. The same conclusion would therefore hold[42] even with arbitrarily high neutron source strength, as from 'a large fraction' of ^{242}Pu (ref. 46) and high ^{238}Pu (ref. 37). Contrary to Meyer *et al.*[43], "slight mistakes in the knowledge of exact isotopic composition" could not "lead to neutralisation of the explosive design" and could indeed be readily accommodated by design.

Selden summarises[31]:

> "It is likely that a nuclear explosive designer would choose to minimise the ^{240}Pu concentration, given the choice. However, *an entirely credible national nuclear explosives capability could be constructed using only reactor grade plutonium.*"

Of course, the designer may choose to avoid the extra fiscal and political cost (if detected) of the *unambiguously military* dedicated facilities required[13] to make large amounts of the more conveniently useable weapons-grade Pu. Some governments may find advantages, notably civilian 'cover', in doing the best they can with their plentiful high-burn-up Pu instead. Recent classified analyses have therefore explored further levels of technological sophistication that can overcome the sub-optimal features of high-burn-up Pu and increase the ~1-kton *minimum* yield of Level Two technology.

Perhaps the most categorical statement of the results comes from a speech[14] by Commissioner Gilinsky (emphasis added):

> "... [S]o far as reactor-grade plutonium is concerned, the fact is that it is possible to use this material for nuclear warheads *at all levels of technical sophistication.* In other words, countries less advanced than the major industrial powers but, nevertheless, possessing nuclear power programs can make very respectable weapons. And, I might add, these are the very countries whose names turn up in every discussion of proliferation. Of course, when reactor grade plutonium is used there *may* be a penalty in performance that is considerable *or insignificant*, depending on the weapon design. But whatever we might once have thought, we now know that even simple [Level Two] designs, albeit with some uncertainties in yield, can serve as effective, highly powerful weapons—reliably in the kiloton range."

The italicised passages imply that further levels of technology exist with still higher yield and predictability than Level Two.

A third level of technology seeks to overcome preinitiation by extremely rapid assembly. The necessary rates of assembly can be calculated and seem to be readily attainable. One published configuration, for example, is stated to be able to compress a sizeable core at several times the 2 mm μs^{-1} radial rate mentioned earlier. Far higher rates are possible with this method, because in a convergent implosive system, shock pressures vary roughly as the inverse fourth power of radius and shock velocities as the inverse square of radius. Applying the same design to a small core can therefore achieve such high assembly velocities that the shock can traverse much of the core and insert very substantial reactivity before hydrodynamic disassembly forces can dominate. The probability of preinitiation then becomes small, the expected yield relatively large, and its dispersion small: in short, the performance penalty approaches the "insignificant"[14].

Calculations suggest that this Level Three technology is sufficient, using reactor-grade Pu, for almost any military objective, even with attempted 'denaturing'[37]. The method will readily occur to most governments and to many technically informed amateurs. The apparatus is not unduly difficult to achieve. It does not necessarily involve a higher technology than Level Two, and should be considered more a logical extension of Level One, a 'smart amateur design', than the exclusive province of governments. It does not necessarily require nuclear testing to ensure confidence in obtaining high yield, provided the maker is confident that the well-characterised non-nuclear components will function as designed. Non-nuclear test firings would, of course, increase this confidence.

Most military bombs are required to function normally in high neutron fluxes such as might arise from nearby nuclear explosions. Essentially the same design considerations apply as in the case of high internal neutron source strengths. It can be safely presumed that these problems are routinely overcome by various means, including thermonuclear techniques that could render the penalty from using reactor-grade Pu not only very small but nil, even at very high yields. This is a very high technology requiring elaborate theoretical, computational, and fabrication facilities, together with prior nuclear testing. But such sophistication is not required for governments or even for some subnational groups to extract from reactor-grade Pu, using Level Three technology, the kind of yield and predictability that the major nuclear powers would have found satisfactory for inclusion in their arsenals around the early 1960s.

Weapons effects and the implications of uncertain yield

Fissioning 1 kg of Pu yields (2.5×10^{24} fissions) × (~180 MeV of prompt energy per fission) $\simeq 7.3\times10^{13}$ J kg^{-1} or $\sim 17\times 10^{12}$ gcal kg^{-1} $\equiv$ 17 kton kg^{-1}. This 17-kton yield (Hiroshima was 13 kton, Nagasaki 22 kton) corresponds to the conversion of a mass defect of only 0.8 g. But unlike chemical high explosives, some of the yield of nuclear explosives appears not as blast or heat but as prompt electromagnetic radiation at many frequencies, especially γ rays, and as prompt neutrons. The smaller the nuclear yield, the more the effects of the nuclear explosion are dominated by prompt radiation.

For example, a 'crude amateur design' yielding only 0.1 kton—which corresponds to fissioning only 6 g (a nominal efficiency of the order of 10^{-3}) and converting a mass defect of 5 mg—typically produces[19,53] 500 rem of prompt γ dose (roughly the LD$_{50}$, or dose likely to kill half those exposed to it) at unshielded ranges up to 300 m, plus 500 rem of prompt neutrons (~LD$_{50}$) to ~450 m, plus 500 rem of fallout exposure (~LD$_{50}$) to 300–1,000 m for people lingering for an hour. Yet such a surface burst makes a crater only ~14 m in radius. Blast damage is also of shorter range than the prompt radiation—severe (overpressure to 10 lb in^{-2} = 0.68 bar) to 150 m and moderate (3 lb in^{-2} = 0.20 bar) to 300 m. The relatively limited blast damage, even at such low yield, however, could amplify the radiation effects by ~10^3 times if used to induce a 1% ground release from an operating 1-GWe LWR (16-GCi inventory), ~10–100 times more from a reprocessing plant.

Effects of larger yields are readily, if roughly, calculable from standard scaling laws[19,53]. For example, a yield of 1 kton, a practical minimum with Level Two technology (but three orders of magnitude larger than a World War II blockbuster), would devastate several km^2, with 500 rem prompt radiation beyond 700 m and with 500 rem fallout around 1–3 km. If a yield Y expected to be 8 kton is in fact only 1 kton, the blast area will diminish not by 7/8 but by 3/4 (as $Y^{2/3}$), and the lethally irradiated area only by half (as $Y^{1/3}$) (refs 1, 53). Such reductions would generally be smaller than the variability in effect expected from the varying circumstances of use; and except in special tactical-warfare conditions, the important thing is not whether the designer can predict the exact yield, but rather that the potential victim cannot.

Conclusions

The above discussion has sought to provide a discreet, selective, but adequate physical basis for understanding the scope for using reactor-grade Pu in fission bombs at some of the diverse levels of sophistication open to various potential users (the taxonomy given is not exhaustive). 'Denaturing' Pu by adding to it, singly or in combination, essentially inseparable[54] neutron-emitting diluents such as ^{238}Pu, ^{240}Pu, ^{242}Pu, or ^{252}Cf (ref. 55)—or indeed any other interfering material that cannot be readily removed, for example, by ion exchange—is "fallacious" and "not a valid concept"[31]. (Dilution with UO_2 or other materials requiring chemical or physical[56] separation is a valid cessed[19,25,34]—but does not solve the problem.) Taking all effects on weapons physics into account, a high ^{238,240,242}Pu content may reduce expected yield to a level that could devastate only a reduce expected yield to a level that could devastate only a modest portion of a city rather than all of it, and may make that yield much less predictable, if the bomb is crudely made. But these faults can be overcome by more clever design, without necessarily using high technology, and at Level Three this can be done by gifted amateurs. It is therefore incorrect to state categorically that bombs made from reactor-grade or deliberately 'denatured'[37] Pu are less effective, less powerful, or less reliable than those made from weapons-grade Pu. Whether these reservations hold, and whether by a meaningful margin, depend on the designer's intentions, skills, and resources, all of which may be unknowable. And the implication that the effects of even a crude, minimal 0.1–1 kton explosion would be tolerable for a free society is at best disingenuous[19–21,27].

The foregoing argument also implies that power reactors are not an implausible but are rather potentially a peculiarly convenient type of large-scale military Pu production reactor. This goes beyond the proposition that

> "... in situations of extreme tension states may turn to second or third best instruments to get their hands on weapons they regard as essential to their security. The point is that, with plutonium readily available, it may be turned to. And those groups within countries that want to go nuclear can pursue an ambiguous path of keeping their options open until the last minute under a commercial disguise"[57].

A government can either manipulate civil fuel cycles to produce substantial amounts of low-burn-up plutonium, or, especially using Level Three technology, use high-burn-up Pu in bombs with insignificant performance penalty. Regardless of possible technical measures[24,25,54,58,59], such Pu will become readily available in quantities of the order of 10^4–10^5 m_c yr^{-1}, and in extracted forms useable for weapons within hours or days, if plans proceed for commercial reprocessing, which is unsafeguardable both today[36] and in principle[14,59,60]. Making even high-burn-up Pu in domestic power reactors incurs no penalty in reactor efficiency or in equipment costs: a reactor-exporting country will gladly build the reactor, train the technicians, and pay for the whole package with generous export subsidies. If extracted, and using any of the numerous means of evading effective safeguards, the Pu discharged from a single large power reactor suffices for about 10^2 bombs per year, a large weapons programme, and there is the alternative of embezzling up to a few bombs' worth per reactor-year from the fuel cycle within its ~1% statistical 'noise', a form of theft that can be made undetectable in principle. The marginal time and money required to use civil reactors for military production are orders of magnitude less[27] than those needed for dedicated military facilities[11,61]. The extra facilities and staff required could be hidden within the civil programme: the "ideal place to hide a tree is in a forest"[61]. And perhaps the greatest attraction of producing military Pu in a power reactor is that it has a civilian 'cover' and thus—at least until regional rivals follow suit—an apparently zero political cost.

In short, the somewhat greater technical difficulty of using power-reactor Pu for effective military bombs—assuming the reactor is actually operated at high fuel burn-up—may be more than counterbalanced by the greater political and economic ease of obtaining that Pu. It "should not be lightly disdained in favour of purer material from dedicated facilities"[61].

Permian–Triassic continental reconstruction of the Gulf of Mexico–Caribbean area

Gary W. White

Department of Geological Sciences, State University of New York at Albany, Albany, New York 12222

The morphology of the margins of Palaeozoic continental crust around the Gulf of Mexico and Caribbean Sea is derived from the distribution of Jurassic evaporites in the Gulf and the distribution of post-Palaeozoic arcs around the Caribbean. The Permian–Triassic position of the continental masses in this region is determined by fitting these margins together to achieve the best agreement of margin morphology and geological continuity. This model is supported by geological observations from the margins and floors of the Gulf and Caribbean and by geometrical considerations derived from continental reconstructions around the Atlantic.

THE plate tectonic evolution of the Gulf of Mexico and Caribbean Sea is poorly understood because a coherent seafloor spreading history based on magnetic anomalies cannot be determined in these basins. Consequently, evolutionary models in this area must be based largely on ambiguous and less precise geological observations from the margins and interpretation of seismic reflection data from the basins. Due to the geological complexities produced by plate kinematics of even geometrically simple systems[1], this approach may not lead to a definitive model, but it constrains the models possible.

Determination of the Permian–Triassic positions of the continents around the Gulf of Mexico and Caribbean Sea is the most critical aspect of all evolutionary models of this region. I propose here a Permian–Triassic reconstruction of the continents around the Gulf of Mexico and Caribbean Sea that emphasises the geometrical constraints imposed by the pre-Mesozoic margin morphology determined for these continents and the fit of the continents around the Atlantic Ocean. The distribution of Jurassic evaporites has a dominant role in determining pre-Mesozoic margins by delimiting the boundaries of Jurassic basins that formed as a result of continental breakup.

Previous models

Although it has been suggested that the Gulf of Mexico existed during the Palaeozoic[2–4], consideration of the stratigraphically controlled seismic reflection data in the Gulf and the geology of the margins of the Gulf and Caribbean support the view that these basins were formed by continental breakup during the Triassic and early Jurassic[6–10]. Several reconstructions have been proposed to close the Gulf of Mexico and Caribbean: the solutions are generally of two types (1) closure by juxtaposing North and South America and relocating Mexico and Central America west of their present position relative to North America[9,11–13] and (2) closure by segmenting and positioning portions of Mexico and Central America between North and South America[6,7,14].

The reconstructions of the first group were supported by the recognition of large strike slip faults in Mexico that provided a means to segment and relocate Mexico and Central America during the late Palaeozoic[4,15,16]. There are also palaeontological, geological and palaeomagnetic data to suggest that South America was very close to North America during the late Palaeozoic[9,11,17]. However, these data lack the resolution to determine precisely the relative positions of North and South America during the late Palaeozoic, and there are several lines of evidence to suggest that they were not contiguous.

One important argument against juxtaposing South America and North America is the absence of a Palaeozoic magmatic arc on either margin. An arc system culminating in late Carboniferous times should have developed as a result of the convergence that formed the Ouachita Mountains. This problem is usually circumvented by placing an inferred arc beneath the thick Mesozoic and Cenozoic sediments of the Gulf Coast (ref. 11, Fig. 2*b*, *c*; ref. 18). However, Wickham *et al.*[19] have shown that this inference is untenable because there are no arc-related, pre-Carboniferous, igneous, metamorphic or sedimentary rocks within the foldbelt; and they interpret the southern margin of North America as a south-facing Atlantic-type margin that

collided with a southern continental mass containing the magmatic arc in Pennsylvanian times. Northern South America is unlikely to be this mass because there are no late-Palaeozoic plutonic rocks east of the Venezuelan Andes[20]. The pre-Mesozoic basement to the Coast Ranges of Venezuela seems to be Precambrian rocks of the Guyana Shield that were intruded and deformed during a Cretaceous arc–continent collision[21].

The paucity of Jurassic evaporites along the northern margin of South America also suggests that closure of the Gulf was not achieved by juxtaposing North and South America as suggested by proponents of the first group. Generally, evaporites formed during initial ocean opening lie on both sides of the resultant ocean[10,22]. There are no evaporites on the northern margin of South America that are of comparable extent to the Louann and correlative evaporites of the Gulf of Mexico[10], and this strongly suggests that North and South America were not opposing margins to the same developing ocean basin.

The most convincing argument against juxtaposing South and North America during the latest Palaeozoic is that this requires disruption of the early Triassic fit of the continents around the Atlantic. Because continents are torsionally rigid, the reconstructed positions of the peri-Atlantic continents provide the most powerful constraint on the relative position of North and South America[23]. Positioning South America against the northern margin of the Gulf of Mexico requires unrealistic offsets of corresponding salt basins and fracture zones along the margins of North America and Africa[8,22].

These arguments against the juxtaposition of North and South America support the models of the second group that close the Gulf and Caribbean without this restriction. However, since the models of Carey[14] and Dietz and Holden[6] were proposed, the Greater Antilles (with the possible exception of part of western Cuba) were found to be of post-Palaeozoic age and therefore they need not be considered in a Triassic reconstruction of this area. Freeland and Dietz[7] considered this in their model, but, by removing these post-Palaeozoic continental masses, large gaps were left between North and South America. Subsequent examination indicated that Blake–Bahama Platform, which was included in the reconstruction of Freeland and Dietz[7], is likely to be an early Mesozoic volcanic construction[8,24] and removal of this platform enhances the problem of large unexplained gaps. In addition, the poor morphological and geological fit of the reconstructed Palaeozoic continental masses as proposed by Freeland and Dietz[7] is not convincing.

Collectively these arguments suggest that the Atlantic fits proposed by LePichon and Fox[8] and Sclater *et al.*[25] best satisfy constraints imposed by palaeontological, palaeomagnetic, morphological and petrological data. Tighter fits such as those of VanderVoo *et al.*[9] and Pilger[13] seem unsatisfactory when the geological evolution of opposing margins of North and South America are considered and the more open fit of Bullard *et al.*[26] creates a gap between North and South America that is too large to be filled with the available pre-Mesozoic continent fragments around the Gulf of Mexico and the Caribbean. Additional difficulty in reconstructing this area results from the extensive alteration of the margin morphology of North, Central and South America during the Mesozoic and Cenozoic. Examination of proposed models therefore suggests that a more precise approximation of the Permian–Triassic positions of continents around the Gulf and Caribbean can be obtained by first removing obvious post-Palaeozoic island arcs and sedimentary constructions and then fitting the resultant margins of continental crust back together in the space dictated by the LePichon and Fox[8] fit of the continents around the Atlantic.

Determination of Palaeozoic margins and proposed reconstruction

The distribution of thick Jurassic evaporites is extremely useful in attempting to define the boundaries of pre-Mesozoic crust that resulted from Triassic rifting in the Gulf of Mexico area. The landward boundaries of these deposits are believed to be the walls of rift valley complexes that developed as the continents separated[22]. In the Gulf of Mexico these thick salt deposits seem to lie on oceanic or greatly attenuated continental crust[27–29]. To a first approximation, they can be used to mark boundaries between the Palaeozoic crust of continental thickness and the developing Jurassic ocean basin (Fig. 1). This simplifying assumption requires the removal of the coastal plains and shelves of Texas, Louisiana and Mississippi and places the pre-Mesozoic crustal margin of North America 200–300 km inland of the present shorelines of Texas and Louisiana (ref. 28, Fig. 3). The hinging of younger deposits over this margin is expressed as a fault zone that stretches from Mobile, Alabama, to San Antonio, Texas[29].

The remaining pre-Mesozoic crustal margins around the Gulf can also be delineated by the distribution of evaporites. The western margin of the Yucatan Block in the Isthmus of Techu-

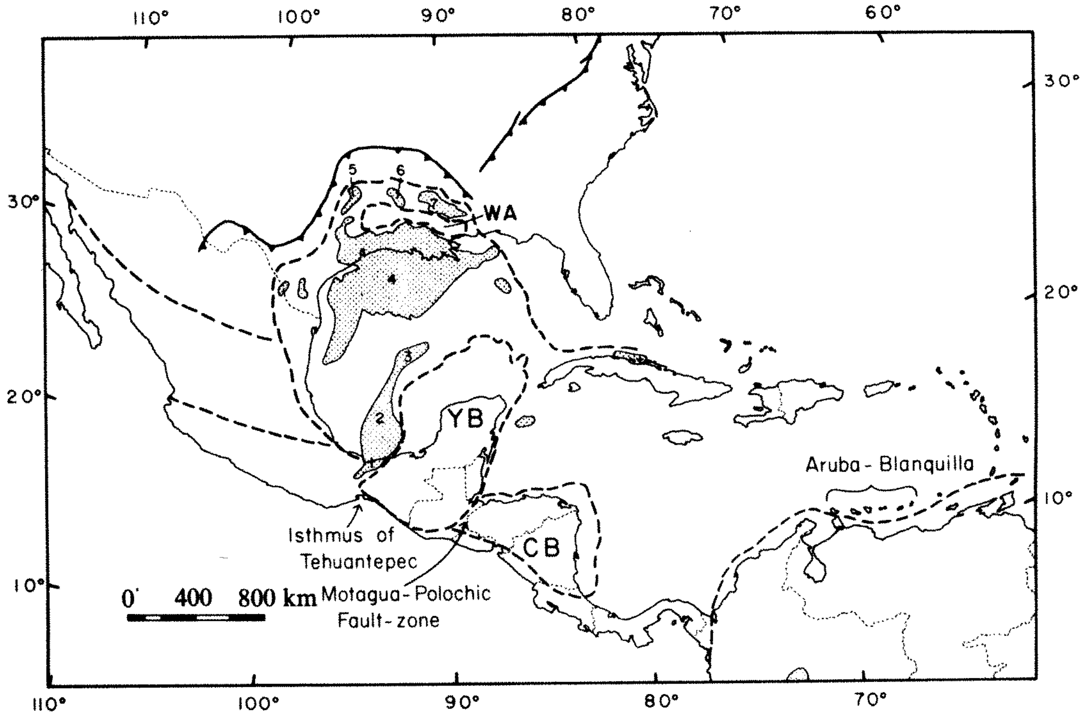

Fig. 1 Map of the Gulf of Mexico and Caribbean Sea showing limits of pre-Mesozoic continental crust (dashed line). YB, Yucatan Block; CB, Chortis Block; WA, Wiggins Arch; 1, Isthmian Basin; 2, Campeche Knolls; 3, Sigsbee Knolls; 4, Gulf Coast Salt Dome Province; 5, East Texas Salt Basin; 6, North Louisiana Salt Basin; 7, Mississippi Salt Basin. Stippling indicates areas of diapiric salt.

antepec is approximately coincident with the eastern edge of the Isthmian Salt Basin, Campeche Knolls and the western limit of Palaeozoic granitic rocks of the Chiapas Mountains near the western border of Chiapas, Mexico (ref. 29, Fig. 1). Seismic reflection studies across the Campeche and Florida Escarpments clearly show pinching out of the Jurassic–Cretaceous (?) Challenger unit (containing the evaporites) against older rocks that form the basement to these shelves[5,30]. These studies and the absence of diapiric salt landward of the Campeche and Florida Escarpments indicate the continental shelves of Yucatan and Florida are underlain by pre-Mesozoic continental crust. Therefore, the Campeche and Florida Escarpments are taken to approximate the Palaeozoic continental crustal margin north and west of Yucatan and Florida respectively (Fig. 1). As shown in Fig. 1, Mexico was segmented into blocks as proposed by Schmidt and Anderson[15].

Determination of the limits of pre-Mesozoic continental crust around the Caribbean is not as straightforward as in the Gulf of Mexico because of the paucity of ocean-opening salts and extensive post-Palaeozoic arc tectonics at the edges of the Caribbean plate. However, most of the circum-Caribbean continental masses are post-Palaeozoic in age, and therefore, only the margins of South America and the Chortis block (Honduras, portions of Guatemala and Nicaragua) need to be considered. The northern margin of South America was formed by rifting in the late Triassic and early Jurassic and experienced intense convergent and strike-slip related deformation after this time[10]. Nonetheless, analysis of the evolution of this margin in Venezuela by Maresch[24] justifies approximating the limits of pre-Mesozoic continental crust between the mainland and the Aruba–Blanquilla Island Chain (Fig. 1).

Two main post-Palaeozoic constructions alter the margins of the Chortis block and are removed in this reconstruction. These are the Nicaraguan Rise, which is a late Mesozoic island arc[31] and the Cenozoic Middle America Arc along the Pacific coast of Guatemala, El Salvador and Nicaragua (Fig. 1). The Motagua–Polochic fault zone marks both the northern boundary of the Chortis block and the southern boundary of the Yucatan block. The eastern and southern limits of the Chortis block are unknown because they are buried under shelf sediments and Tertiary volcanics, but for this reconstruction the eastern limit is approximated by the 1,000-m isobath and the southern limit is approximated by projecting the trend of this isobath across Central America (approximately coincident with the southern Nicaraguan border).

The peri-Gulf and Caribbean blocks, now refined to their pre-Mesozoic shapes, can be assembled as shown in Fig. 2. In making this late Permian–early Triassic assembly opposing margins were matched when possible by closing correlative salt basins. Without this constraint, pre-Mesozoic margins were placed to provide the best morphological and geological fit. Application of this principle to the Gulf of Mexico indicates the extensive salt deposits west and north of Yucatan (Isthmian Basin, Campeche Knolls and the Sigsbee Knolls) correspond in age and extent to those of the northwestern margin (Gulf Coast Salt Dome Province). It is believed these were opposing margins of the developing Jurassic ocean[22,23]. Good morphological agreement of pre-Mesozoic continental boundaries determined from salt distribution not only fixes the relative position of the Yucatan block to the southern margin of North America (Fig. 2), but also justifies the method of margin approximation described earlier. The Wiggins Arch, believed to be a pre-Mesozoic continental horst, is placed north-west of its present position against the North American Palaeozoic margin by closing the Mississippi, North Louisiana and East Texas Salt Basins. The wedge-shaped gap that remains between Yucatan and Florida can most easily be filled by placing the southeastern margin of the Chortis block against the Florida Escarpment.

Positioning the Yucatan and Chortis blocks in this manner entirely fills the gap between North and South America that is produced by the Atlantic reconstructions of LePichon and Fox[8] and Sclater *et al.*[25]. The small elongate gaps south of Florida and Yucatan (Fig. 2) may represent continental crust obliterated during the Bahama–Cuba and Motagua Collisions respectively. The remaining portions of Mexico must be displaced northwestwards of their present position before the opening of the Gulf. Whether or not this was accomplished by displacement along the Mohave–Sonora shear zone and the site of the Mexican volcanic zone (ref. 15, Fig. 1) or some other boundary must await further study. Palaeomagnetic data from Mexico and Central America[33] are difficult to interpret because of extensive post-Jurassic deformation in these regions. Pre-Mesozoic portions of Cuba are assumed here to be small and, therefore, do not alter the positions of the major blocks, but the present position of Cuba relative to the Yucatan and Chortis blocks suggests placing this continental crust at the juction of these blocks with the North American margin (area C in Fig. 2).

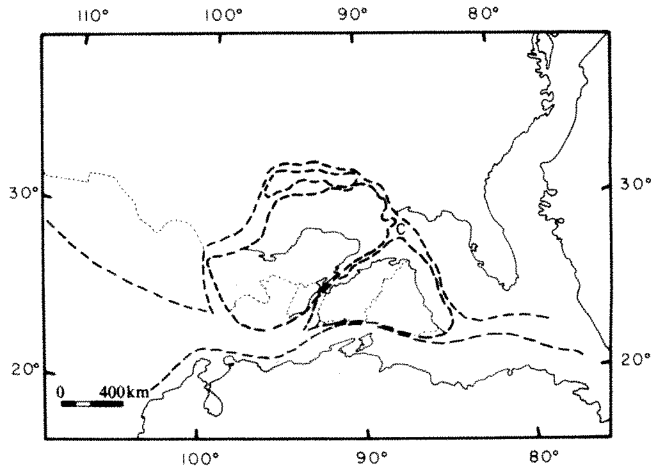

Fig. 2 Reconstructed positions of the continents around the Gulf of Mexico and Caribbean Sea during the early Triassic. C, Location of pre-Mesozoic portions of Cuba.

Discussion and implications

This reconstruction satisfactorily explains many features observed around the Gulf and Caribbean region. Most notably it explains the late Triassic to early Jurassic rifting event seen on the margins of the Gulf of Mexico and northern South America without juxtaposing North and South America and without leaving large gaps between these two continents. The Triassic La Quinta and correlative redbeds of Venezuela and Colombia and the early Jurassic Apoteri tholeiitic basalt flows of Guyana and Brazil[34] suggest that the Triassic graben complex associated with the Gulf–Atlantic opening extended into South America; but the subsequent seafloor spreading that occurred in some of these graben to open the oceanic basins between North and South America was not synchronous. Continuity of the Challenger seismic unit across the central Gulf[5,29] indicates that seafloor spreading in the Gulf ceased at least by the end of Challenger deposition. Therefore, the Gulf was largely created in Lias–Dogger times. However, subsidence of the northern margin of South America which began in the late Jurassic[21] suggests seafloor spreading in the Caribbean began in Malm times and continued into the Cretaceous.

The presence of extensive ocean-opening evaporites in the Gulf of Mexico and the paucity of evaporites in the Caribbean area may be explained by this geometry and timing of basin development. Figure 2 suggests that Mexico and Florida served as structural barriers against open ocean circulation in the Gulf as the Yucatan and Chortis blocks moved away from North America until Medial Jurassic times. At this time, communication with the developing Atlantic Ocean was established through the old Bahama channel and extensive evaporite deposition ceased in the Gulf. Apparently no such barriers restricted circulation in the developing Caribbean which was in constant communication with the Pacific and Atlantic Oceans as it opened.

This reconstruction also suggests that the Palaeozoic magmatic arc resulting from closure of the Ouachita Ocean to form the Ouachita Mountains is likely to be found as the basement to Mesozoic sediments in Yucatan. Discovery of rhyolite of Silurian age showing a Mississippian metamorphic event (collision?) in the Yucatan No. 1 well of the Central Yucatan Peninsula[35] supports this view. I suggest that the granites and volcanic rocks that underlie Lower Jurassic (?Triassic) redbeds of Yucatan described by Lopez-Ramos[36] may also belong to this arc system. This arc was probably the source of middle Palaeozoic granitic and rhyolitic clasts and andesite tuffs in the Upper Palaeozoic flysch sequences of the Ouachitas[37].

Further support for this configuration is found in the Palaeozoic rocks of northeastern Mexico. The pre-Mesozoic schist, metaquartzite, granite and Devonian gneiss of eastern Coahuila and Nuevo Leon, cannot be correlated with Palaeozoic terrains in Chihuahua, Mexico, or the Ouachita belt in the southern US[37], but these rocks are remarkably similar to the pre-Mesozoic schist, granite and gneiss terrains of the Chiapas Mountains of the Isthmus of Tehuantepec[25]. I suggest that these terrains were contiguous during the Palaeozoic (Fig. 2).

The pre-Mesozoic rocks (predominately phyllite, marble and schist)[35] of the Chortis block are not easily correlated with others in the Gulf or Caribbean region and its position in this reconstruction is largely based on morphology. However, phyllite and marble dredged from the Yucatan Channel near the north-east corner of the Yucatan Peninsula[38] and schist found in the Basil Jones No. 1 well in Belice[36] are possible correlatives and as such they support location of the Chortis block as proposed in Fig. 2.

Correlation of pre-Mesozoic terrains between northern South America, the Yucatan block and the Chortis block is difficult because of the complex history of the northern South American margin. In general, Upper Palaeozoic rocks are restricted to a smooth curvilinear belt that extends from the Appalachians into the Andes, but these correlations are too crude to fix precisely the position of South America. Nevertheless, continuity of Palaeozoic terrains, good morphological agreement between South America and the other continental blocks (Fig. 2), and the Mesozoic tectonic history of northern South America[10,21] support this reconstruction.

The margins of the Yucatan, Chortis and Mexican blocks probably originated as intracontinental transform fault zones that were coaeval with the collision of Laurasia and Gondwanaland. Continued crustal shortening after collision probably caused shuffling of these blocks resulting in the complex late Palaeozoic to early Mesozoic deformation in Mexico and Central America as suggested by Dengo[35]. I thank K. C. Burke, S. E. DeLong, J. F. Dewey, P. J. Fox, W. S. F. Kidd, R. E. Livaccari, A. M. C. Sengör and J. B. Stroup for useful suggestions, R. Carosella for assistance in preparing this paper, and Kevin Burke and Bill Kidd for helpful discussions. This work was supported by NSF grants EAR 7514254 and EAR 7803319 awarded to Kevin Burke.

Abelson murine leukaemia virus protein is phosphorylated *in vitro* to form phosphotyrosine

Owen N. Witte, Asim Dasgupta & David Baltimore

Department of Biology and Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

The Abelson murine leukaemia virus protein (P120) can become phosphorylated in vitro *by [γ-^{32}P]ATP. The protein has been purified from cell membranes to the point that in specific conditions virtually all of the incorporated ^{32}P is in P120. The reaction is stimulated by Mn^{2+} and Mg^{2+} but not Ca^{2+} and is very rapid even at 0 °C. The phosphate is linked to P120 at tyrosine, a linkage not previously reported for a phosphorylation reaction. Phosphorylation may be involved in the transforming activity of viruses that cause leukaemia as well as sarcomas.*

ABELSON murine leukaemia virus (A-MuLV) is a defective retrovirus that causes a thymus-independent leukaemia[1,2]. The leukaemic transformation can be carried out in cultures of bone marrow, fetal liver or spleen cells and many of the resultant cell lines have the characteristics of pre-B-lymphocytes[3]. Continuous lines of fibroblastic cells can also be transformed by the virus[4].

The A-MuLV genome is a hybrid consisting of about 25% of the genome of Moloney murine leukaemia virus (M-MuLV) flanking an insert of 3.6 kilobases of sequence that is homolo-

0028-0836/80/090826—06$01.00

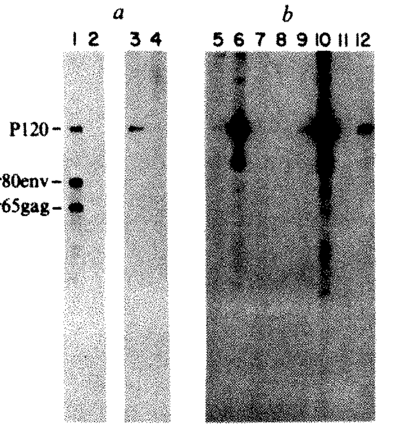

Fig. 1 Phosphorylation of P120 in an immunoprecipitate. *a*, 2M3/M cells (an A-MuLV-transformed BALB/c lymphoid cell line superinfected with Moloney-MuLV[7]) were labelled with ^{35}S-methionine (2.5×10^6 cells, 100 μCi ^{35}S-methionine in 3 ml Dulbecco's minimal essential medium minus methionine for 1 h). Cells were extracted and clarified for immunoprecipitation[7,9], then one half was reacted with 5 μl anti-A-MuLV tumour serum[9] (lane 1) and one half with 5 μl normal mouse serum (lane 2). Precipitates were collected with *S. aureus*, denatured and analysed on a SDS 10% polyacrylamide gel developed by fluorography[25,26]. An equal number of unlabelled 2M3/M cells was extracted and clarified as above and immunoprecipitated with anti-A-MuLV tumour serum (lane 3) or normal mouse serum (lane 4). The precipitates were washed with 20 mM Tris-HCl, *p*H 8.0, by centrifugation, and resuspended in 50 μl of 20 mM Tris, *p*H 8.0, 10 mM $MgCl_2$, containing 1 μCi [γ-^{32}P]ATP (NEN, 2,300 Ci mmol^{-1}) for 10 min at 30 °C, washed, denatured and analysed by electrophoresis as described above. *b*, For each lane, 1×10^6 2M3 cells (an A-MuLV transformed lymphoid non-producer cell line) were extracted and clarified, then immunoprecipitated with 5 μl of a polyvalent goat anti-M-MuLV virion serum[9]. Individual precipitates were tested for phosphorylation of P120 as described above, with the following cations present: lane 5, 1 mM $CoCl_2$; lane 6, 10 mM $CoCl_2$; lane 7, 1 mM $CaCl_2$; lane 8, 10 mM $CaCl_2$; lane 9, 1 mM $MnCl_2$; lane 10, 10 mM $MnCl_2$; lane 11, 1 mM $MgCl_2$; lane 12, 10 mM $MgCl_2$.

gous to the DNA of normal mouse cells[5,6]. Only a single protein of the A-MuLV genome has been identifiable using a wide range of sera; in the prototype A-MuLV strain, it is called P120 and represents a fusion of the N-terminal segment of molecular weight (MW) 30,000 of the M-MuLV gag protein precursor to protein of MW 90,000 that is non-viral[7,8]. An antiserum specific for the non-MuLV-related portion of P120 has been prepared and reacts with protein of MW 150,000 in normal mouse cells[9,10]. Thus, the non-viral portion of the P120 is closely related to a normal cell protein and is encoded by information that has at least partial homology to normal cell DNA.

Because no conditional mutants of A-MuLV are known, it has not been possible to prove that the P120 is the viral transforming protein, but because it is the only defined product of the genome and because of its association with A-MuLV-induced transformed cells, it has been assumed to be responsible for transformation by A-MuLV[2,3]. The antiserum that recognises the non-M-MuLV-related portion of the P120 also reacts with the external surface of the plasma membrane of A-MuLV-transformed cells; thus, the P120 seems to have a portion exposed outside the cell[9]. Anti-M-MuLV sera do not react with the surface of A-MuLV-transformed, non-producer cells, indicating that the M-MuLV gag determinants are inside the cell. The protein therefore seems to be a transmembrane protein of the plasma membrane. P120 is not detectably glycosylated and is not cleaved by protease treatment of live cells; most of the polypeptide is therefore probably not exposed to the outside of the cell.

P120 is phosphorylated[7]. This observation led us to examine whether its properties might be related to those of the Rous sarcoma virus transforming protein, pp60 src. That protein, which is recovered as a phosphoprotein from infected cells, has been shown to catalyse the incorporation of ^{32}P from [γ-^{32}P]ATP into the heavy chain of immunoglobulins that bind to it [11,12]. The original demonstration of phosphorylation by pp60src was carried out with immunoprecipitates bound to *Staphylococcus aureus* and we therefore began our studies with such a system.

P120 phosphorylation in immunoprecipitates

To examine P120 for phosphorylation activity, an immunoprecipitate was incubated with [γ-^{32}P]ATP essentially as described by Collett and Erikson[11] for the Rous sarcoma virus transforming protein. Lysates were prepared from ^{35}S-methionine-labelled or from unlabelled A-MuLV-transformed lymphoid cells (2M3/M) (the cells also contained M-MuLV proteins because they were superinfected with M-MuLV). The extracts were mixed with control serum or antiserum directed

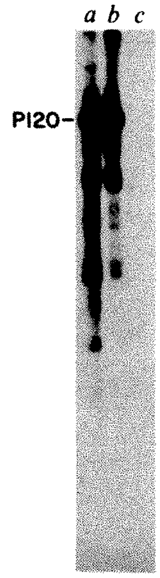

Fig. 2 Preparation and specificity of a soluble system that incorporates phosphate into P120. A frozen pellet of 2×10^9 2M3 cells was extracted at 0–4 °C with a detergent extraction mix of 100 ml of 10 mM NaH_2PO_4–Na_2HPO_4, *p*H 7.5, 100 mM NaCl, 1.0% Triton X-100, 0.5% Na deoxycholate, 0.1% SDS, 10% glycerol, 1 mM EDTA and 5 mM phenylmethylsulphonyl fluoride. This was clarified at 20,000 r.p.m. for 2 h in a Sorvall RC-5 refrigerated centrifuge. To the supernatant fluid was added 20 ml packed volume of DEAE-cellulose in the same buffer. The supernatant was recovered by centrifugation and then batch absorbed to 20 ml packed volume of phosphocellulose. P120 binds to phosphocellulose in these conditions as monitored by immunoprecipitation of ^{3}H-leucine-labelled cellular lysates (data not shown). The resin was washed with the extraction buffer and P120 eluted with 30 ml of 0.5 M NaCl in extraction mix. The eluted material was dialysed against 10 mM KH_2PO_4–K_2HPO_4, *p*H 8.0, 100 mM NaCl and 25% glycerol. The dialysate was reconcentrated by absorption to phosphocellulose on a small column (1.2 × 10 cm) and elution into 4 ml of 0.5 M NaCl extraction buffer minus the SDS, containing 25% glycerol. This preparation represented 3% of the total protein in the original lysate and the recovery of P120 (estimated from experiments using labelled cellular lysates) was about 80%. This preparation was stable for over 6 weeks when stored at −20°C. The enzyme preparation (5 μl) was assayed in a 50-μl reaction mix containing 20 mM Tris HCl, *p*H 8.0, 10 mM $MnCl_2$ and 1 μCi [γ-^{32}P]ATP for 10 min at 30 °C. One portion was analysed by electrophoresis to display all the phosphorylated proteins (lane *a*). An equal portion was immunoprecipitated with 5 μl of goat antiserum to total M-MuLV virion proteins (lane *b*; as in Fig. 1 and refs). A third equal portion was treated with 5 μl of normal goat serum (lane *c*). Analysis on SDS 10% polyacrylamide gel and autoradiography as in Fig. 1.

towards the A-MuLV-specific region of the P120 protein as well as the helper virus proteins. Immunoprecipitates were collected on fixed *S. aureus* immunoabsorbant. The precipitates from unlabelled cells were incubated with [γ-^{32}P]ATP and Mg^{2+} for 10 min at 30 °C and washed. The ^{35}S-labelled samples and ^{32}P-labelled samples were then denatured and analysed by SDS-polyacrylamide gel electrophoresis. The ^{35}S-labelled sample had, as expected from previous work[7,9], a strong band of P120 precipitated by immune but not normal serum (Fig. 1*a*, lanes 1, 2). The ^{32}P-labelled precipitates also showed a band of radioactivity at MW 120,000 when precipitated by the immune but not the normal serum (Fig. 1*a*, lanes 3, 4). This experiment has been carried out with a variety of antisera directed at the gag or A-MuLV-specific regions of the P120 (refs 7, 9), and with a variety of A-MuLV-transformed cells that lacked the M-MuLV proteins, and labelling of the 120,000-MW protein has always occurred. Thus, the ^{32}P-labelled protein has the immunological as well as the electrophoretic characteristics of P120 and therefore seems to be P120 itself. No labelling of immunoglobulins was evident nor was there labelling of the M-MuLV proteins Pr65gag and Pr80env that were present in the immunoprecipitate (Fig. 1*a*, lane 3).

Table 1 Kinetic stability of the phosphate covalently bound to P120

Cation	First incubation [ATP]	First incubation c.p.m. × 10^{-3}	Second incubation [ATP]	Second incubation c.p.m. × 10^{-3}
Mg	10 nM	21.2	10 nM	17.9
	10 nM	21.2	500 µM	15.6
	500 µM	1.6	ND	
Mn	10 nM	63.1	10 nM	59.7
	10 nM	63.1	500 µM	56.4
	500 µM	2.8	ND	

All reactions were carried out at 30 °C for 10 min in 20 mM Tris, *p*H 8.0, containing Mg or Mn at 10 mM in 50 µl final volume using 10 µl of phosphocellulose-purified enzyme. The first incubation contained either only radioactive [γ-^{32}P]ATP (NEN, 2,400 Ci mmol^{-1}) at 10 nM final concentration or the same amount of radioactive ATP plus added unlabelled ATP to 500 µM final concentration. The total c.p.m. incorporated was determined by cold 5% trichloroacetic acid (TCA) precipitation. For the second incubation, duplicate reactions from the first set of incubations using the 10 nM ATP condition were reincubated (10 min, 30 °C) with no additional ATP or with unlabelled ATP to 500 µM final concentration and c.p.m. incorporated determined as above. ND, Not determined.

To examine the cation specificity of ^{32}P incorporation, different ions were tested at 1 and 10 mM. Mn^{2+} and Co^{2+} were most effective, Mg^{2+} was less effective and Ca^{2+} supported no detectable incorporation (Fig. 1*b*). In all cases where incorporation was seen, 10 mM cation was preferable to 1 mM. Ca^{2+} added to Mn^{2+} did not inhibit incorporation (data not shown). These effects were similar over an ATP concentration range of 20 nM–1 mM.

A variety of other variables were examined and their effects monitored semi-quantitatively by estimating band intensities following electrophoresis. [γ-^{32}P]GTP was found to be a ^{32}P donor to P120 but at much lower efficiency than [γ-^{32}P]ATP. Labelling with [γ-^{32}P]ATP (at 10–20 nM) was complete within about 1 min even at 0 °C and the yield was about the same at 37 °C or 0 °C. Variation of the *p*H from 6 to 9 had little effect. No effect was noted when cyclic AMP, cyclic GMP or any of the four ribonucleoside monophosphates or diphosphates was added at 10–500 µM. When 10–50 µM of any of the four ribonucleoside triphosphates was added to 10 nM [γ-^{32}P]ATP in the presence of Mg^{2+}, a threefold stimulation of incorporation of ^{32}P into P120 was seen. This effect is most remarkable for ATP because ATP will directly dilute the specific activity of the [γ-^{32}P]ATP. The result may imply a regulatory role for nucleoside triphosphates (NTPs) in the reaction. Less stimulation by NTPs occurred in the presence of Mn^{2+}.

A soluble system for P120 phosphorylation

Because the behaviour of P120 in immunoprecipitates might be misleading, we have developed a partial purification scheme for P120 starting with a detergent extract of infected cells. The purification was monitored using ^{3}H-leucine-labelled extracts and immunoprecipitation with specific antiserum as in Fig. 1, lane 1. P120 did not bind to DEAE-cellulose but bound to phosphocellulose and could be eluted at about 0.5 M NaCl. In the crude extract as well as in the phosphocellulose-purified material, ^{32}P incorporation from [γ-^{32}P]ATP into P120 could be demonstrated by immunoprecipitation after the reaction. After phosphocellulose purification, as much as 85% of the acid-insoluble ^{32}P could be immunoprecipitated. At that stage, the electrophoretic profiles of equal amounts of the total reaction product (Fig. 2, lane *a*) and the immunoprecipitated product (Fig. 2, lane *b*) were quite similar. No radioactive bands were evident when normal serum was used in place of the immune serum (Fig. 2, lane *c*), although about 5% of the incorporated ^{32}P appeared in the precipitate after treatment with normal serum. The various labelled bands other than P120 that were precipitated by immune serum probably represented labelled degradation products of P120 that were produced during the incubation. This degree of specific phosphorylation by the phosphocellulose fraction has been confirmed in three separate preparations and a wide variety of reaction conditions.

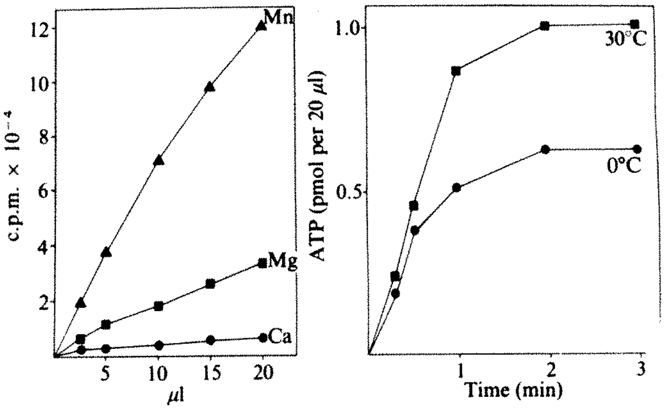

Fig. 3 Properties of the soluble P120 phosphorylation reaction. *a*, Varying amounts of an enzyme preparation prepared as described in Fig. 2 legend were reacted for 10 min at 30 °C in a final 50 µl volume containing 1 µCi [γ-^{32}P]ATP, 20 mM Tris, *p*H 8.0, and 10 mM CaCl$_2$ (○), MgCl$_2$ (□) or MnCl$_2$ (△). Labelled proteins were precipitated with 1 ml of cold 5% TCA, collected and washed by Millipore filtration and counted in 5 ml of Bray's solution. *b*, An enzyme preparation (10 µl) was reacted in 50 µl final volume containing 50 µm ATP, 10 mM MnCl$_2$ and 20 mM Tris, *p*H 8.0, at 0 °C or 30 °C for the times shown. Reactions were stopped by addition of cold 5% TCA, collected and counted as above. Longer times of reaction (5–30 min) showed no increase above the 2-min level (data not shown).

Although this fraction is enriched for P120, analysis of its total protein content by Coomassie blue staining of SDS-polyacrylamide gels showed more than 50 separate bands of varying intensity (data not shown). P120 was so minor a component that we could not identify a specific band of P120 protein in this mixture.

Characterisation of the soluble phosphorylation reaction

Because the majority of ^{32}P incorporated by the phosphocellulose fraction was incorporated into specifically immunoprecipitable material, the properties of this fraction were investigated further using an acid precipitation assay. The yield of the incorporation was a linear function of the concentration of added protein but, as in the immunoprecipitate reaction, Mn^{2+} was greatly preferred over Mg^{2+} and Ca^{2+} was virtually inactive (Fig. 3*a*). The reaction yield was a function of the ATP concentration and was half maximal at about 10 μM. At 50 μM ATP, the reaction showed a rapid time course at either 0 °C or 30 °C but at 30 °C 30–40% more incorporation was evident than at 0 °C (Fig. 3*b*). Cyclic AMP or cyclic GMP did not affect the reaction (data not shown).

Because sufficient P120 could be added to incorporate ^{32}P corresponding to about 10–15% of added [γ-^{32}P]ATP into acid-precipitable material, the fate of the substrate was examined. Preliminary experiments showed that at 30 °C ATPase and phosphatase activities in the phosphocellulose eluate, possibly unrelated to P120, degraded much of the added ATP. At 0 °C and with Ca^{2+} added, these were suppressed without affecting P120 labelling and therefore these conditions were used for the experiments. Equal amounts of enzyme were incubated at 0 °C for 15 min with equal molar amounts of either [γ-^{32}P]ATP (Fig. 4, lanes *a–c*) or [α-^{32}P]ATP (Fig. 4, lanes *d–f*) using Ca^{2+} (lanes *a*, *d*), Mn^{2+} (lanes *b*, *e*) or Mn^{2+} and Ca^{2+} (lanes *c*, *f*); portions of the reactions were analysed by ascending chromatography. With Ca^{2+} alone, some degradation of both [γ-^{32}P]ATP to P_i and [α-^{32}P]ATP to ADP/AMP was evident but with Mn^{2+} present much more ADP was found than in its absence. Also, when Mn^{2+} was added, appreciable radioactivity from [γ-^{32}P]ATP became protein bound and remained at the origin. Approximately the same fractions of the ^{32}P in [γ-^{32}P]ATP became protein bound as the fraction of [α-^{32}P]ATP that was converted to ^{32}P-ADP. Thus, only the γ-phosphate of ATP seemed to participate in the labelling of P120, and ADP was released.

To examine whether the ^{32}P incorporated into P120 was turning over during the reaction, the [γ-^{32}P]ATP (10 nM) was diluted with a great excess of unlabelled ATP (500 μM) after 10 min of reaction and another 10 min of incubation was carried out (Table 1). With either Mg^{2+} or Mn^{2+} present, little loss of radioactivity was evident during the second incubation, although the excess of added ATP was sufficient to reduce the initial incorporation of ^{32}P by 10- to 30-fold. Thus, the phosphate incorporated in P120 was not subsequently released as acid-soluble products.

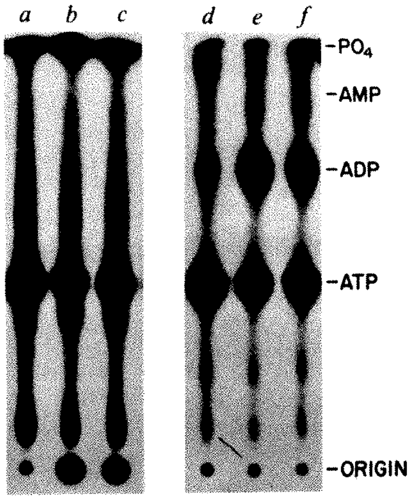

Fig. 4 Fate of ATP during the P120 phosphorylation reaction. Phosphorylation reactions (100 μl final volume) contained 20 μl of enzyme preparation and either 1 μCi of [γ-^{32}P]ATP (lanes *a–c*) or [α-^{32}P]ATP (lanes *d–f*). Both ATPs were adjusted to 600 Ci $mmol^{-1}$. Also present were 20 mM Tris, *p*H 8.0, and 10 mM $CaCl_2$ (lanes *a*, *d*), 10 mM $MnCl_2$ (lanes *b*, *e*) or 10 mM $CaCl_2$ plus 10 mM $MnCl_2$ (lanes *c*, *f*). Reactions were at 0 °C for 15 min and were then diluted 20-fold into excess EDTA. Aliquots of 1 μl of each were analysed on polyethylenimine-coated thin layer plates (Brinkman, PEI 300) by ascending chromatography in 0.85 M K_2HPO_4, adjusted to *p*H 3.5. Positions of ^{32}P-PO_4 and marker nonradioactive AMP, ADP and ATP (visualised under UV light) are shown.

Identification of the P120-phosphate bond as phosphotyrosine

As an initial characterisation of the bond between the protein and the phosphate, the acid and alkali stabilities of the product were studied (Table 2). Neither 0.1 M HCl nor 0.1 M NaOH released any acid-soluble radioactivity after 30 min at 37 °C. Even 1 M HCl at 37 °C released no detectable ^{32}P, but 2 M HCl at 100 °C for 20 h converted all the protein-bound ^{32}P to inorganic phosphate. These properties were inconsistent with the acid lability of phosphate linkages to nitrogen[13] and the general lability of acylphosphate linkages[14]. Furthermore, the 2 M HCl hydrolysis should have released some phosphoserine or phosphothreonine if they were present[11].

All the radioactivity could be released from ^{32}P-P120 as $^{32}PO_4$ by treatment with calf intestinal phosphates or bacterial alkaline phosphatase (Fig. 5). This cleavage could be inhibited by the addition of pure phosphomonoester compounds like phosphoserine (data not shown). In this experiment, the ^{32}P-P120 was predigested with chymotrypsin in an attempt to increase the sensitivity of ^{32}P-P120 to hydrolysis but in other experiments this has proved unnecessary. Thus, the bond between the ^{32}P and the protein behaved like a phosphomonoester.

To search for phosphomonoesters that were more labile to acid than phosphoserine or phosphothreonine, a preparation of ^{32}P-P120 from the *in vitro* phosphorylation system was hydrolysed at 100 °C in 6 M HCl for 0, 2, 4 or 6 h and the products were separated by *p*H 3.5 electrophoresis (Fig. 6, lanes *a–d*). Before hydrolysis, the radioactivity remained at the origin but at all times of hydrolysis extensive production of free $^{32}PO_4$ was evident. Also evident after hydrolysis was a prominent spot co-migrating with a phosphotyrosine standard. The apparent

Table 2 Stability of the phosphate bond in *in vitro* phosphorylated P120

* 8,000 c.p.m. of *in vitro* phosphorylated P120-P prepared and washed free of unincorporated [γ-^{32}P]ATP as described in Fig. 6 legend was treated in 200 μl of the solution indicates.

† Samples were precipitated with cold 5% TCA, collected and washed on Millipore filters and counted in Bray's solution. The control is set at 100%.

‡ Following hydrolysis, the samples were concentrated by lyophilisation and analysed by high voltage electrophoresis at *p*H 3.5 as described in Fig. 6 legend. Autoradiograms with orthophosphate markers were used to locate the spot of free phosphate, which was excised and counted by Cerenkov radiation. ND, Not determined.

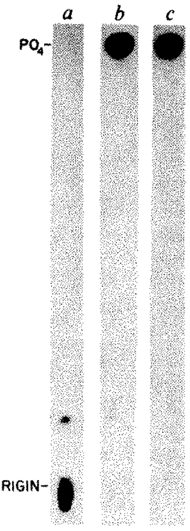

Fig. 5 Susceptibility of ^{32}P-P120 to phosphatase. *In vitro* phosphorylated P120 prepared in a soluble reaction (10 mM $MnCl_2$, 1 μCi [γ-^{32}P]ATP, 20 mM Tris, *p*H 8.0, 20 μl enzyme preparation, 0 °C, 10 min) was precipitated with cold TCA and washed with ethanol to remove unincorporated ATP. The pellet was resuspended in 100 mM NH_4HCO_3, digested with α-chymotrypsin (10 μg ml^{-1}, 37 °C, 12 h), and then boiled for 5 min. Portions containing 2,500 c.p.m. were untreated (*a*), digested with calf intestinal phosphatase (0.01 units, Boehringer Mannheim (*b*) or bacterial alkaline phosphatase (0.01 units, Worthington) (*c*) in 20 mM NH_4HCO_3 and 5 mM $MgCl_2$ for 30 min at 37 °C. Aliquots of 5 μl were analysed by high voltage electrophoresis (Savant) in pyridine acetic acid (*p*H 3.5) on Whatman 3-MM paper at 2,400 V for 1 h. The position of a ^{32}P-PO_4 standard is noted.

phosphotyrosine was eluted and chromatographed with an internal phosphotyrosine marker (Fig. 7). Phosphoserine and phosphothreonine migrated closer to the front than phosphotyrosine in this system. Trace amounts of a compound migrating with phosphoserine were also released by hydrolysis of this preparation (Fig. 6, lanes *b–d*) but recovery of phosphoserine has been variable and always small.

Phosphotyrosine is known to be more acid labile than either phosphoserine or phosphothreonine[15]. Thus, although the yield of ^{32}P-phosphotyrosine was never more than 40–50% of the input radioactivity in ^{32}P-P120, the virtual lack of phosphoserine and phosphothreonine, coupled with the sensitivity of all the ^{32}P to phosphomonoesterases (Fig. 5), is consistent with the interpretation that almost all ^{32}P in ^{32}P-P120 is actually in phosphotyrosine linkage. This report, and a recent independent observation on middle T antigen of polyoma virus[20], appear to represent the first direct demonstrations that phosphotyrosine can occur as a distinct entity in phosphoproteins, although three examples of a tyrosine-*O-P*-nucleotidyl linkage have been reported (refs 16–19 and J. Wang, personal communication). Although the occurrence of phosphotyrosine may represent a unique or very rare situation, the possibility that this linkage is commonly missed because of its acid lability should be considered.

P120 has previously been shown to be labelled in cells exposed to $^{32}PO_4$. To examine whether this *in vivo* phosphorylation occurs at tyrosine residues, *in vivo*-labelled ^{32}P-P120 was hydrolysed in acid using the same conditions as described for the *in vitro*-phosphorylated protein (Fig. 6, lanes *e–h*). The *in vivo* label was recovered mainly as phosphoserine or free phosphate. Virtually no phosphotyrosine was evident and the small spot that migrated just ahead of phosphotyrosine had too little radioactivity to be analysed further. It thus seems that most of the *in vivo* phosphorylation occurs at serine residues, but the extensive release of ^{32}P as inorganic phosphate could suggest that more labile bonds are also present. P120 contains the M-MuLV gag protein pp12 which is known to have serine residues that can be phosphorylated[19]; perhaps some or all the phosphoserine in the *in vivo*-labelled P120 is located in the pp12 region of the molecule.

Interpretation of the P120 phosphorylation reaction

The properties of the P120 phosphorylation reaction described here are unique and not easily interpretable. First, the linkage of phosphate to tyrosine is a unique one and thus offers no clue to its function. We have recently become aware that an apparent autophosphorylation of polyoma virus middle T antigen has also been shown to involve phosphotyrosine. Thus, phosphotyrosine is involved in more than one viral protein thought to play a part in transformation[20]. Second, the reaction seems to be an autophosphorylation. Although it is difficult to be certain whether any other proteins are involved in the reaction, no protein other than P120 is present in the immunoprecipitates at even 10% of the level of P120 and yet rapid phosphorylation of P120 occurs in the immunoprecipitate even at 0 °C. The M-MuLV proteins (evident in Fig. 1, lane 1) are not involved because an immunoprecipitate from cells lacking M-MuLV proteins was active in P120 phosphorylation. Third, the rapid reaction even at 0 °C is suggestive of the formation of an intermediate in an enzyme reaction. The stability of the phosphate-protein linkage after dilution of the [γ-^{32}P]ATP indicates that the reaction as it occurs is not catalytic phosphate transfer. It is, of course, quite possible that the protein kinase reaction is meant to produce a stable tyrosine phosphorylation but it is significant that P120 from cells labelled with ^{32}P-PO_4 had little or no phosphotyrosine.

One attractive possibility is that P120 is a phosphotransferase or phosphatase, but that in the assay conditions used here it is

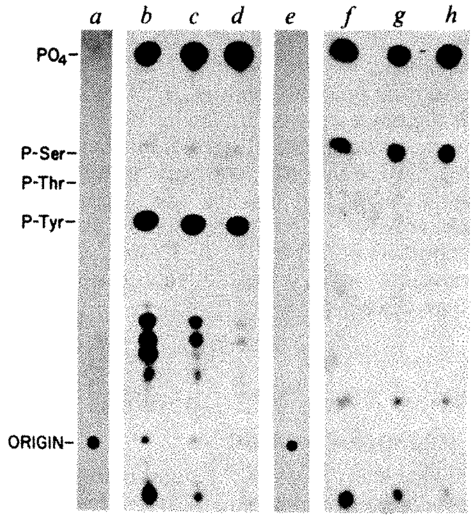

Fig. 6 Analysis of acid hydrolysates of phosphate-labelled P120 made *in vitro* and in cells. About 5,000 c.p.m. of *in vitro* phosphorylated P120 (0 °C, 10 mM $MnCl_2$ reaction conditions as for Fig. 3) recovered by immunoprecipitation, was washed with TCA and ethanol to remove unincorporated [γ-^{32}P]ATP and was either left untreated (*a*) or hydrolysed with 6 M HCl at 100 °C, in a sealed ampoule for 2 h (*b*), 4 h (*c*) or 6 h (*d*). About 2,000 c.p.m. of *in vivo* phosphorylated P120 (2 × 10^6 2M3 cells labelled in phosphate-free medium with 200 μCi of ^{32}P-PO_4 for 3 h, lysed and immunoprecipitated as for Fig. 1, lane 1) was washed with TCA, ethanol and was either left untreated (*e*) or hydrolysed with 6 M HCl at 100 °C for 2 h (*f*), 4 h (*g*) or 6 h (*h*). Samples were lyophilised, resuspended in 5 μl water and a portion analysed by high voltage electrophoresis (*p*H 3.5) as in Fig. 5. The position of marker phosphoserine, phosphothreonine and phosphotyrosine[15] was determined by ninhydrin staining.

unable to transfer the phosphate from its linkage to tyrosine. By this postulate, the P120 phosphorylation could be a partial reaction. Possibly, we need to find the appropriate substrate for phosphate transfer, but two other interpretations should be considered: (1) that removal of P120 from its normal association with membranes has prevented a second step that it ordinarily carries out; thus, we might trap an intermediate state. (2) P120 might initially form a bond other than phosphotyrosine but might transfer the phosphate to tyrosine because of an altered configuration due to its removal from membranes. The P120 is a fused product of viral information and part of a cellular gene; possibly the tyrosine is in the viral portion and is not normally available in the cellular product. We have previously reported that only extracts of A-MuLV-transformed cells could function in *trans* to label heat-inactivated A-MuLV protein of another strain when both were mixed before immunoprecipitation and phosphorylation assay[21]. Extracts of normal cells or cells transformed by other agents were ineffective. One possibility is that the active form for phosphorylation of P120 is a dimer or higher multimer of like subunits. Such preformed complexes would account for the rapid time course and allow for the rescue of heat-inactivated subunits by reforming complexes with native subunits provided in *trans*.

Comparison with Rous sarcoma virus pp60src

Although A-MuLV selectivity transforms lymphoid and occasionally other haematopoietic cells in infected animals, it will transform cultured fibroblastic cell lines[3,4]. Thus, in culture, it can behave like a sarcoma virus and it is not too surprising that the P120 has some parallels with the Rous sarcoma virus protein (pp60src). That protein, like P120 (ref. 9), is membrane associated[22], suggesting that transformation events may often take place at the cell surface. The A-MuLV protein is known to have a portion extending out of the cell because antisera that immunoprecipitate P120 also stain the exterior membrane of live, A-MuLV-transformed cells[9]. With pp60src, the antisera only label the internal surface of the plasma membrane but this could reflect differences in the determinants recognised by the available sera rather than fundamental differences in the organisation of the protein.

Another parallel between pp60src and P120 is that both are involved in phosphorylation reactions. The major activity of pp60src, however, is *trans*-phosphorylation of acceptor proteins (such as immunoglobulin, phosvitin). By contrast, P120 causes little or no labelling of added protein (data not shown) or of the immunoglobulin that binds to it. Whether this difference is fundamental or is a peculiarity of the specific systems is unclear but some phosphorylation of pp60src itself has been noted[23].

Although pp60src has not been reported to form phosphotyrosine, this question needs further investigation. Other properties of the pp60src and P120 reactions have similarities, the major one being that both reactions occur rapidly at 0 °C. Also, Ca^{2+} will support neither reaction but is not inhibitory to either one.

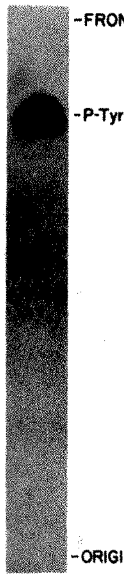

Fig. 7 Co-chromatography of phosphotyrosine with the major phosphorylated amino acid recovered from *in vitro* phosphorylated P120. Material from the prominent spot migrating on high voltage electrophoresis as phosphotyrosine shown in Fig. 6, lane *d*, was eluted with water, mixed with authentic phosphotyrosine, concentrated by lyophilisation and analysed by ascending chromatography on cellulose thin layer plates (Brinkman, CEL 300) in saturated ammonium sulphate: 1 M sodium acetate: isopropanol (40:9:1)[27]. The dashed line shows the position of the ninhydrin-stained phosphotyrosine internal marker.

Richert *et al.*[24] have argued that pp60src is more like a nucleotide kinase than a protein kinase, although the only demonstrated activity of pp60src is protein kinase activity. As described above, P120 of A-MuLV also has properties that suggest its autophosphorylation activity may represent formation of an enzyme intermediate, although we would not single out nucleotide kinases as the best parallel.

In summary, both the Rous sarcoma virus protein, pp60src, and the A-MuLV protein, P120, are membrane-associated, phosphorylating proteins that show rapid reactions at 0 °C (refs 22, 24). Early proteins of SV40 and polyoma, two other transforming viruses, also are phosphorylated *in vitro* and at least one of these seems to be phosphorylated at a tyrosine residue[20]. These similarities suggest that the leukaemogenic (and fibroblast transformation) activity of A-MuLV, the sarcomagenic activity of Rous sarcoma virus and the generalised transforming potential of DNA tumour viruses may have a similar basis.

This work was supported by grants from the American Cancer Society and the NIH. O.N.W. is a postdoctoral fellow of the Helen Hay Whitney Foundation. D.B. is an American Cancer Society Research Professor. Marker phosphorylated amino acids were from Dr J. Wang.

Note added in proof: T. Hunter and B. M. Sefton (*Proc. natn. Acad. Sci. U.S.A.*, in the press) and R. Erikson and colleagues (personal communication) have recently shown that the protein kinase activity associated with pp60src of Rous sarcoma virus specifically phosphorylates tyrosine residues.

The amino acid residues involved in the areas of contact that stabilise the haemoglobin S polymer fibre seem to be the same ones that stabilise the basic unit of the deoxyhaemoglobin S crystal: the Wishner–Love double strand. The haemoglobin S fibre is probably formed by a unique packing of these double strands.

ANALYSIS of the supramolecular structure of the deoxyhaemoglobin (deoxy Hb) S polymer has been attempted by diffraction of high resolution electron microscopy plates[1] and by X-ray crystallography of aligned fibres[2]. A detailed description of the structure, however, must account for data about specific amino acid residues which alter the polymerisation. Our laboratory has approached this problem with a strategy that utilises binary mixtures of Hb S and Hb variants with mutations of residues at the molecular surface[3,4]. Since the predominant species in such mixtures are hybrid tetramers of the type $\alpha_2\beta^s\beta^x$ or $\alpha\beta^s\alpha^x\beta^A$, their behaviour can show whether the mutated residue affects the polymerisation of Hb S. This article describes several residues at the surface of the tetramer that appear to be involved in areas of contact in the polymer and compares these to the contacts found in deoxy Hb S crystals by Love and associates[5].

Isolation of mutants and other experimental procedures

Haemolysates were made from blood samples obtained after informed consent from donors with sickle cell anaemia (SS) diagnosed and characterised in our Heredity Clinic. These haemolysates were selected to contain less than 5% Hb F (measured as the alkaline-resistant fraction[6]) and were used without further purification. Hb Hope was obtained from a homozygous donor and contained less than 1% Hb F, and less than 2% Hb A_2 as measured by column chromatography[7].

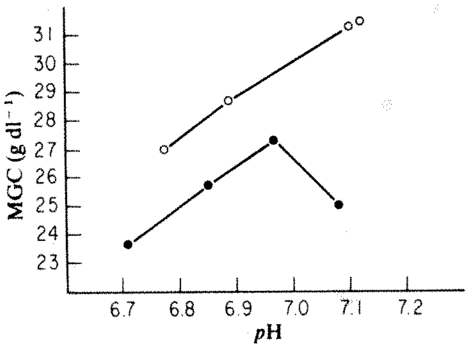

Fig. 1 Minimum gelling concentration (MGC) of Hb S (40%) + Hb A (60%) (○), and Hb S (40%) + Hb I Toulouse (60%) (●) at different pH. Hb I Toulouse when mixed with Hb S promotes gelation as compared to Hb A. Buffer: 0.15 M KPO_4, Temperature 24 °C.

The other haemoglobin variants used in these studies were isolated from haemolysates of heterozygotes' blood by chromatography on columns of DE-52 (Whatman) using 0.05 M Tris-HCl buffer with a pH between 7.5 and 8.2, depending on the haemoglobin, as described elsewhere in detail[4]. The characterisation of Hb Manhasset (β139 Asn → Lys) will be reported separately[8]. All samples were concentrated and simultaneously dialysed against 0.15 M potassium phosphate (pH 7.35) and minimum gelling concentrations were determined at 24 °C as described previously[9].

In some of the experiments we use dithionite to reduce methaemoglobin and/or to assure complete deoxygenation. The dithionite solution was prepared by mixing the powder anaerobically with 0.001 M NaOH. An appropriate aliquot of this solution was added anaerobically to the deoxygenated haemoglobin mixture. The final solution contained 1.2 M of dithionite per mol of haem and the final pH was consistently 6.9.

Rationale of the experimental design

We had previously proposed on the basis of indirect evidence[9] confirmed by others[10] that the two β-chains of Hb S behave unequally in the formation of the polymer. More recently, we obtained direct evidence[11] that only one of the β6 valine substitution sites of the Hb S tetramer is actively involved in an area of contact. The symmetrical area in the other β^s chain is not involved in any area of contact[12]. Due to the symmetry rela-

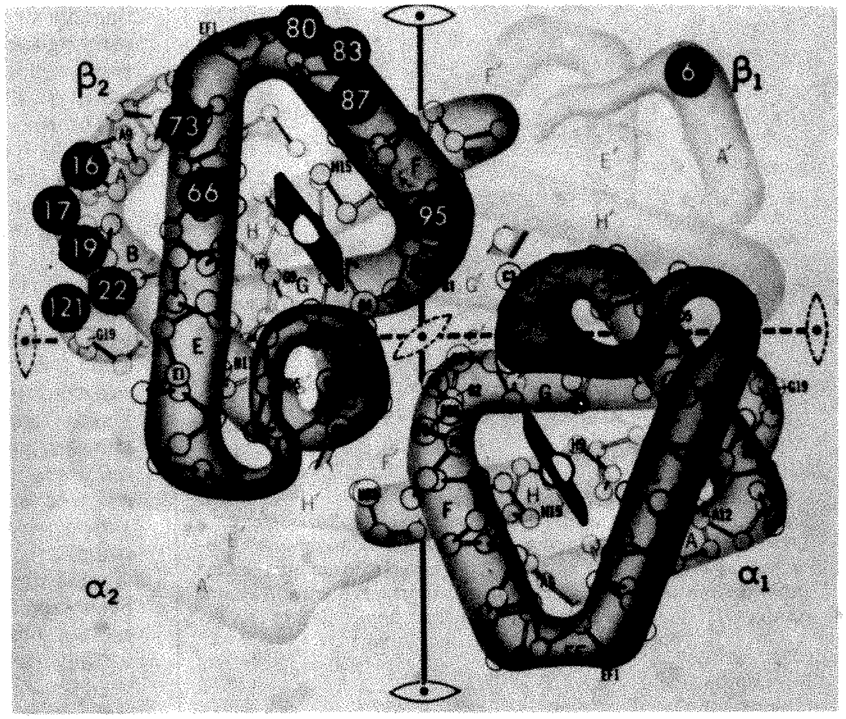

Fig. 2 Mutational sites (black circles with white numbers) that have been shown to interfere with the polymerisation of Hb S in solution. This diagram is a modification of a figure by Irving Geis. References for the mutations not reported here can be found in ref. 12. The diagram uses the nomenclature of Perutz for helical and nonhelical segments. White digits correspond to sequence numbers. Note that all mutational sites described correspond to the $\beta 2$ chain when $\beta 1$ is carrying the active 6-Val site.

tionships between the chains in the haemoglobin tetramer each β-chain has a different set of interactions with each of the α-chains. With one of the α-chains, a β-chain forms a highly stable system of strong hydrophobic and polar interactions resulting in a very stable $\alpha 1\beta 1$ dimer. The same $\beta 1$ chain forms weaker interactions with the $\alpha 2$ chain so that the $\alpha 1\beta 2$ interface is broken when the tetramer dissociates into dimers. These considerations highlight the need to define the effect of a surface residue specifically in terms of its activity in $\alpha 1$, $\alpha 2$, $\beta 1$, or $\beta 2$, in relation to the 'active' $\beta 6$ valine site.

To define β-chain interaction sites, we mix Hb S with the β-chain variant, Hb X (generally in the proportion of 40% Hb S and 60% Hb X). The predominant species in the mixture (because of the dimerisation of both parental tetramers and subsequent free rearrangement) is the hybrid $\alpha_2\beta^s\beta^x$. It is obvious that this allows us to measure the activity of the mutant residue located *trans* to the β-chain carrying the active $\beta 6$ Val substitution. In order to explore the effects of *cis* residues, Hb variants with two mutations in the same β-chains are required, one of which is identical to the Hb S substitution. Three such double mutants have been examined[3]. If the minimum gelling concentration of the doubly mutated Hb is abnormal, further information pertaining to the *cis* or *trans* character of the effect can be obtained by mixing this variant with Hb A and observing the behaviour of the hybrid $\alpha_2\beta^{s,x}\beta$.

Effect of several β mutations on Hb S polymerisation

The results obtained with the β-chain mutants are summarised in Table 1. Of the 14 mutants examined, 6 altered the polymerisation of Hb S. Mutations at sites $\beta 16$, $\beta 17$, $\beta 19$, $\beta 83$ and $\beta 95$ had an inhibitory effect, whereas the mutation at site $\beta 66$ facilitated polymerisation (Fig. 1), an effect similar to that found with substitutions at $\beta 121$ (Hb O Arab and Hb D Los Angeles)[13,14]. It should be emphasised that the assignment of these residues to areas of interaction pertain exclusively to the $\beta 2$ chain *trans* to the $\beta 1$ chain designated as the one carrying the active 6-Val site. The effects of the corresponding *cis* residues in the sequence of the $\beta 1$ chain remain to be defined. The magnitude of the alterations of gelation in mixtures with Hb S suggests that $\beta 66$ and the nearby $\beta 73$ site (previously studied)[15,16] is part of an important single area of interaction between the tetramers of the polymer.

Figure 2 shows all the β-chain sites that have been implicated in areas of contact, including the ones reported here. Those that have been examined and found thus far not to participate are listed in Table 2.

Assigned sites of interaction and the Hb S crystal

Wishner and his associates[5] have described the crystal structure of deoxy Hb S and found that the basic unit is a double strand stabilised with side-to-side and up-down interactions involving mainly the β-chains (Figs 3, 4). A salient feature of this structure is that only one of the β-chains has a 6-Val residue involved in a contact area. This is in accordance with our data on the formation of the Hb S polymer[12]. The relevance of this structure to the deoxy Hb S fibre can be tested further by determining if other contacts found in the crystal structure can be shown to be active in polymerising solutions of deoxy Hb S. Of the sites examined thus far, $\beta 66$, $\beta 73$, $\beta 83$ and $\beta 87$, which were found to be involved in the side-to-side contact of the crystal, were also

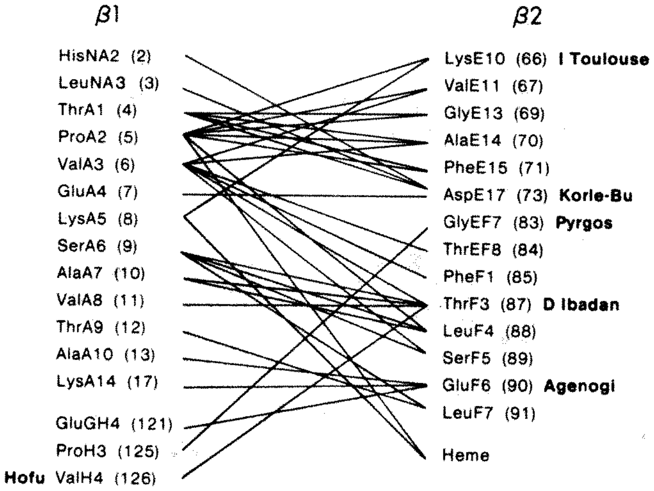

Fig. 3 Side-to-side contacts in the Wishner–Love double strand[5]. Lines connect residues within a 5 Å radius. Contiguous to the sequence site, we have indicated (in bold letters) the mutant used to explore that site. All the side-to-side interactions involve β-chain residues. Residues are identified by Perutz nomenclature and in parenthesis by the sequence number.

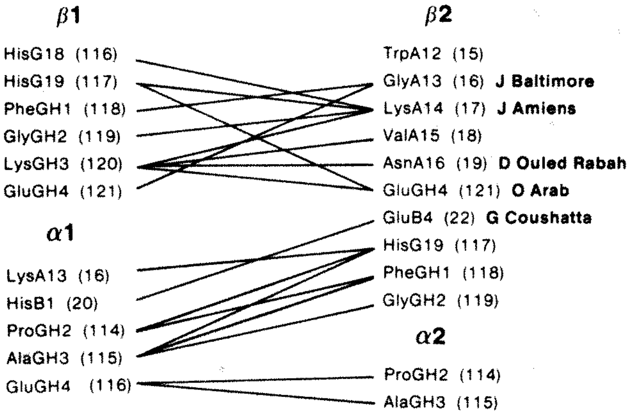

Fig. 4 Up-and-down contacts in the Wishner–Love double strand[5]. Lines connect residues within a 5 Å radius. Contiguous to the sequence site we have indicated (in bold letters) the mutant used to explore that site. Nomenclature as in Fig. 3.

found to have strong effects on the polymerisation of solutions of Hb S (Fig. 3). Note that these residues were shown to be part of the receptor site located in the β2 chain of the crystal (the β1 chain carries the 'active' β6-Val site). This, of course, is in complete agreement with our results, as our experimental design with Hb S–Hb X mixtures detects only the effects of the mutant β^x residues in the β2 chain. A further interesting point can be made with regard to the residue β126, that we have explored using Hb Hofu. Although β126-Val participates in the interacting site of the crystal it is provided by the same (β1) chain carrying the active 6-Val site. We do not find any effect of this residue, but this is not in contradiction with the crystal data, in which β2 126 is *not* in an area of contact.

Three residues are not coincident with the crystal data. Residue β80, implicated by the inhibitory effect of Hb Gifu[4], is not present in the side-to-side contact area, but it is very close, as demonstrated by the fact that residue β83 is involved. In addition, in the Hb F crystal, β80 is featured in this area of contact[17]. The residue at β90 is included in the side-to-side contact in the crystal, but we find that it is inactive in solution. It should be remembered, however, that this residue is at the edge of the contact area and interacting residues have been included using a radius of 5 Å (ref. 5) which is rather large relative to expected hydrogen bond distances and Van der Waals radii. Finally, residue β95, which we have examined using two mutants, is not involved at all in the areas of contact between the tetramers in the crystal double strand. This residue could be involved in other contacts that are specific for the fibre.

Now we turn to the up–down interaction along the crystal strand axis (Fig. 4). Of the residues involved by the crystallographic map of deoxy Hb S, β16, β17, β19, β22 and β121 have been examined. All of them have been found to be active in solution (Table 1, Fig. 2).

Conversely, of the 21 β-residues examined thus far that have been shown to be inactive in solution, 20 of them are not found in the areas of contact between the tetramers forming the double strands of the crystal (Table 2). The only exception was β90, as noted above.

In terms of the α-chain sites, there are only five contact sites provided by α1 and two contact sites provided by α2 that stabilise the up–down contacts of the double strand in the crystal. Of these, only α116 has been examined by Benesch *et al.*[18]; but until it is established whether the effect found is attributable to the α2 or α1 chain, this data cannot be used to test the crystal relevance to the solutions of Hb S.

Conclusions

The data presented here show remarkable coincidence between the crystallographically defined contact sites for the double strands of deoxy Hb S and the residues that appear to be active in solutions undergoing polymer formation. This suggests that the double strand is the building unit in the assembly of the fibre. At first approximation the supramolecular structure proposed by Dykes *et al.*[1] could be accommodated with seven double strands as defined in the crystal.

It should be kept in mind that the crystal and fibre cannot be identical structures. It is likely that residues of the α chain involved in the stabilisation between double strands in the crystal are not significant for the fibre. The stabilisation of the double strands present in the fibre may involve interactions between the α-chains which are not present in the crystal. The definition of these α–α contacts will provide the evidence required to establish the packing order of the Wishner–Love double strand in the haemoglobin S fibre.

Abnormal expression of chromosomal rabbit β-globin gene in *Saccharomyces cerevisiae*

Jean D. Beggs*, **Johan van den Berg**†, **Albert van Ooyen** and **Charles Weissmann**

Institut für Molekularbiologie I, Universität Zürich, 8093 Zürich, Switzerland and *Plant Breeding Institute, Trumpington, Cambridge CB2 2LQ, UK

A 5.1 kilobase-pair segment of rabbit chromosomal β-globin DNA was joined to pJDB219, a plasmid consisting of pMB9, the 2-μ yeast plasmid and the yeast leu-2 *gene.* Saccharomyces cerevisiae *transformed with the globin DNA-containing hybrid produced β-globin-specific RNA. As compared to mature β-globin mRNA, these transcripts lacked* 20–40 *nucleotides from the 5′ end, contained all of the small intron and extended to about the middle of the large intron. Thus, no splicing of the primary β-globin transcript could be detected in the yeast cells.*

PROKARYOTIC cells are, in general, unlikely to provide an adequate environment for the spontaneous expression of chromosomal genes of higher eukaryotes. Besides the incompatibilities to be expected at the levels of RNA and protein synthesis, the existence within eukaryotic genes of intervening sequences (see ref. 1 for references), which are copied into primary transcripts and subsequently eliminated (see ref. 2 for references) by processes so far unknown in prokaryotes, suggests that only eukaryotic cells are promising hosts for testing the physiological expression of eukaryotic genes.

Yeast, as a lower eukaryote, is a possible candidate for such a test system. Vectors containing the yeast 2-μ plasmid are suitable for high frequency transformation of yeast[3–5], presumably because this plasmid replicates in yeast cells, yielding relatively high copy numbers and thus allowing maintenance without integration.

pJDB219, a hybrid DNA consisting of pMB9, the 2-μ yeast plasmid and the *leu*-2 gene of yeast, is maintained predominantly in plasmid form in yeast[3]. We have transformed *Saccharomyces cerevisiae* with a hybrid consisting of pJDB219 and a cloned rabbit chromosomal DNA segment including a complete β-globin gene with two intervening sequences and extended flanking regions[6,7]. We found that yeast thus transformed contained β-globin-specific transcripts 800–900 nucleotides long; however, these do not have normal termini and have not undergone splicing. An abstract of this work has been presented[8].

Transformation of yeast with cloned rabbit β-globin chromosomal DNA

A 5.1 kilobase-pair fragment of rabbit chromosomal DNA, containing a β-globin gene, has been cloned in plasmid pCRI (Z-pCRI/RchrβG-1) and characterised by restriction analysis[6]; the nucleotide sequence of the gene and its flanking regions was

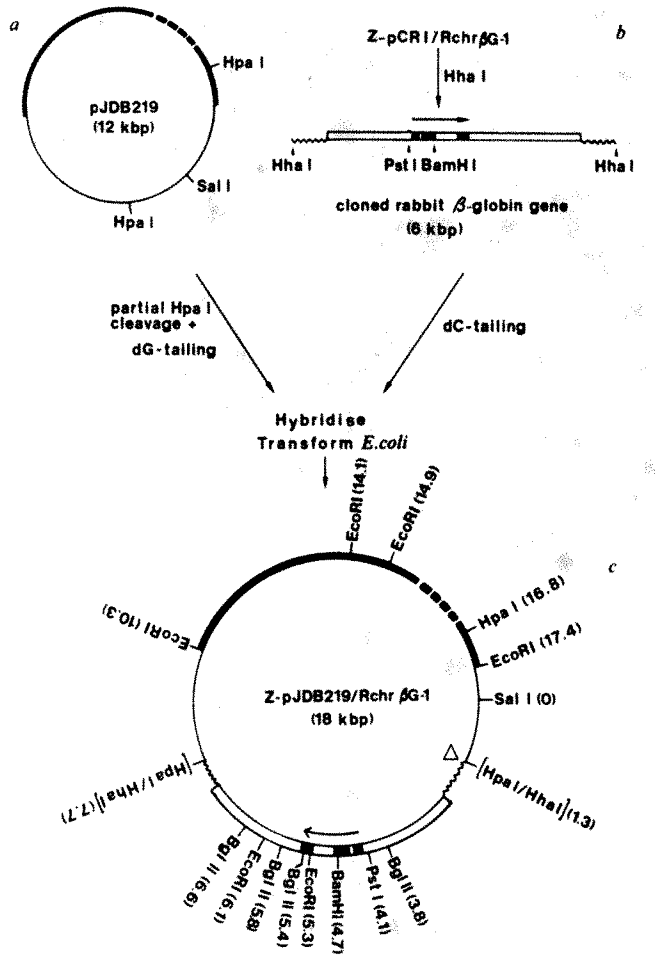

Fig. 1 Construction of hybrids consisting of rabbit chromosomal β-globin DNA, the 2-μ yeast plasmid, the yeast *leu*-2 gene and plasmid pMB9. The hybrid plasmid pJDB219 (*a*), consisting of pMB9 (thin lines), the 2-μ yeast plasmid (thick lines) and the *leu*-2 gene (dashed line) was partially digested with *Hpa*I, the fragments were separated on a 0.6% agarose gel and full-length linear DNA (12.4 kilobases) was extracted, purified on DEAE-cellulose[14], digested with λ exonuclease and elongated with dGMP residues using terminal transferase[22]. The chromosomal β-globin plasmid Z-pCRI/RchrβG-1 (ref. 6) was cleaved with *Hha*I, the globin-DNA-containing 6.4-kilobase fragment (*b*) purified by sucrose gradient centrifugation and elongated with dCMP residues[22]. The elongated plasmid and globin DNAs (40 ng and 10 ng, respectively) were hybridised in 50 μl 50 mM Tris-HCl (*p*H 7.6), 100 mM NaCl, 5 mM EDTA for 1 h each at 65 °C, 46 °C and 37 °C, and used to transform *E. coli* χ1776 (ref. 6). Eight tetracycline-resistant clones were obtained and screened by the Grunstein–Hogness[9] procedure using ^{32}P-labelled β-globin cDNA as probe[19]. Two plasmids, Z-pJDB219/RchrβG-1 and -3 (abbreviated to YRβG-1 and YRβG-3), characterised by restriction analyses as shown in Fig. 2, were recloned in *E. coli* HB101 and used for further work. Both plasmids had the globin insert in the orientation shown (*c*); YRβG-3 has a 1,400 base pair deletion at the position indicated by Δ.

---

† Present address: Gist-Brocades, Postbus 1, Delft, Holland. ‡ Present address: Imperial College of Science and Technology, London SW7 2AZ, UK.

0028–0836/80/090835—06$01.00

determined by van Ooyen *et al.*[7]. The rabbit DNA sequence (with pCRI-derived flanking segments) (see Fig. 1) was excised with *Hha*I and elongated with dCMP residues at the 3′ termini. pJDB219, which contains two *Hpa*I sites, one in the 2-μ yeast plasmid region, the other within the pMB9 moiety, was partially cleaved with *Hpa*I, the full-length linearised molecules were isolated, and elongated with dGMP residues (see Fig. 1). *Escherichia coli* χ1776 was transformed with the hybridised mixture of the two DNAs, and tetracycline-resistant clones containing the globin sequence were identified by the Grunstein–Hogness[9] procedure, using ^{32}P-labelled cloned β-globin cDNA as probe. Hybrid plasmids from two colonies were recloned in *E. coli* HB101, because the original clones contained a minor species of plasmid without a globin insert. Two isolates, Z-pJDB219/RchrβG-1 and Z-pJDB219/RchrβG-3 (abbreviated to YRβG-1 and YRβG-3), contained the β-globin *Hha*I fragment in the *Hpa*I site of the pMB9 moiety in the orientation shown in Fig. 1. The two hybrid plasmids were of different size. As shown by restriction analysis (Fig. 2), YRβG-3 contained a deletion of about 1.4 kilobases at or near the junction between the plasmid and the 5′ proximal part of the globin DNA insert. Both hybrids contained the complete globin-specific DNA, as shown by the presence of the 1.7 and 0.4 kilobase *Bgl*II fragments.

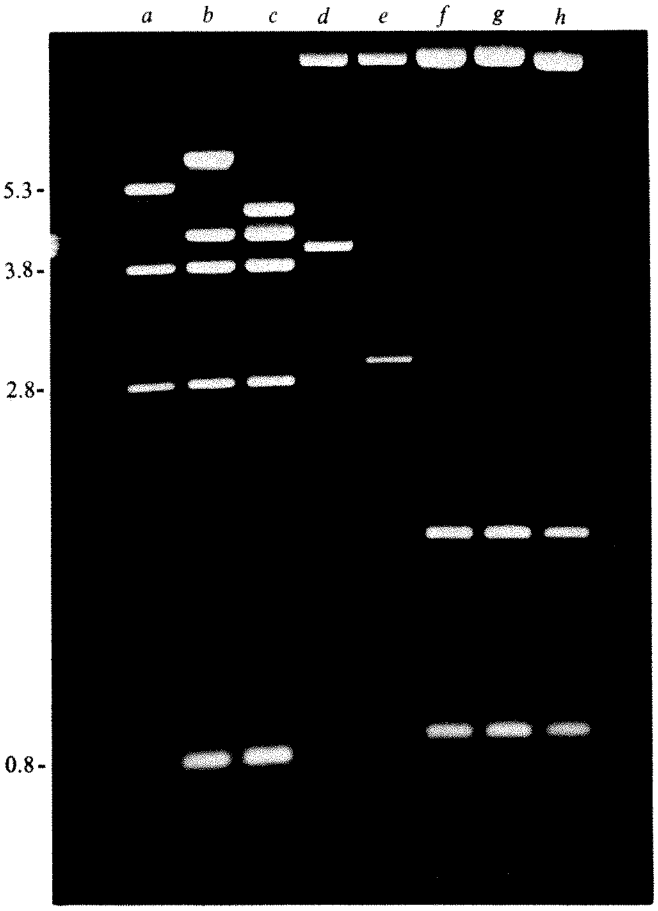

Fig. 2 Restriction site analysis of hybrid plasmids YRβG-1 and YRβG-3, containing pMB9, the 2-μ yeast plasmid, the yeast *leu*-2 gene and a rabbit β-globin chromosomal DNA segment. Plasmid DNA was prepared from transformed *E. coli* HB101, by lysing bacteria with SDS[23] or Triton X-100 (ref. 24), centrifuging, and separating linear and circular DNA by the procedure of Currier and Nester[25], as outlined in Wilkie *et al.*[26]. DNA was digested with the restriction enzymes indicated below and the products analysed by electrophoresis through a 1% agarose gel in 40 mM Tris, 20 mM sodium acetate, 1 mM EDTA (*p*H 8.2). The gels were stained with ethidium bromide and photographed in UV light. *a*, *b* and *c*, *Eco*RI-digested pJDB219 (ref. 3) (*a*), YRβG-1 (*b*) and YRβG-3 (*c*); *d*, YRβG-1 and *e*, YRβG-3, both doubly digested with *Sal*I and *Pst*I; *f*, *g* and *h*, *Bgl*II-digested Z-pCRI/RchrβG-1 (*f*), YRβG-1 (*g*) and YRβG-3 (*h*). The orientation of the inserts was deduced from the sizes of the two largest fragments obtained by digestion with *Eco*RI (*b*) and (*c*), or *Sal*I and *Pst*I (*d*) and (*e*) (compare Fig. 1), and was confirmed by double digestion with *Eco*RI and *Pst*I or *Eco*RI and *Sal*I (not shown).

S. cerevisiae MC16 leu$^-$ (ref. 3) was transformed with YRβG-1 and YRβG-3 isolated from *E. coli* χ1776 or *E. coli* HB101, and leucine-independent colonies were isolated. One yeast clone from each transformation experiment was examined in greater detail. The results described below were the same regardless of whether YRβG-1 or -3 was used, or whether the plasmid had been recloned or not. Total DNA from the transformed yeast clones, as well as the original hybrid plasmid DNAs were digested with *Pst*I and *Bgl*II, and subjected to agarose gel electrophoresis. The DNA fragments were transferred to nitrocellulose filters[10] and hybridised to ^{32}P-labelled cloned β-globin cDNA. As shown in the autoradiogram of Fig. 3, the pattern of globin-specific bands given by the transformed yeast DNA was the same as that of the original β-globin DNA -containing plasmid Z-pCRI/RchrβG-1. From the intensity of the bands relative to those of known amounts of β-globin DNA we estimate that there were multiple copies of globin DNA per cell. Transfer of uncleaved DNA from transformed yeast according to Southern[10] followed by hybridisation with ^{32}P-labelled, cloned β-globin cDNA gave several bands; most preparations lacked DNA with the mobility of YRβG-1 or YRβG-3. Thus, the hybrid plasmid had been rearranged in the yeast; however, the globin-specific sequence was not changed, as shown by Fig. 3.

Characterisation of β-globin-specific transcripts in yeast

To determine whether globin-specific RNA had been synthesised in the transformed yeast cells, total RNA was subjected to agarose gel electrophoresis in denaturing conditions, transferred to diazobenzyloxymethyl paper[11], and hybridised with ^{32}P-labelled, cloned β-globin cDNA. As shown in Fig. 4, a strong β-globin-specific band with a mobility corresponding to an RNA of 800–900 nucleotides was found in yeast cells transformed with either YRβG-1 or YRβG-3. This RNA is thus longer than mature rabbit β-globin mRNA, about 700 nucleotides[12], but shorter than the 15S β-globin precursor RNA, about 1,450 nucleotides[13], including the poly(A) tails in both cases. By comparing the intensity of the globin-specific RNA band with that of known amounts of β-globin mRNA, we estimate that about 0.01% of the total yeast RNA was β-globin-specific.

The β-globin-specific RNA was further characterised by a modification[14,15] of the Berk–Sharp[16] hybridisation technique. To map the 5′ terminus of the transcript, a 223 base-pair restriction fragment of the cloned β-globin chromosomal DNA extending from the *Mbo*II cleavage site within the first exon (position 128) to the *Pst* site 95 nucleotides upstream from the beginning of the mRNA[7], labelled at the 5′ terminus of the minus strand (*Mbo*II cleavage site), was prepared. This probe was denatured and hybridised with the RNA sample in 80% formamide. After digestion with endonuclease S$_1$, the sample was denatured and the labelled DNA sized by polyacrylamide gel electrophoresis in 7 M urea. A radioactive DNA fragment is recovered if the labelled 5′ terminus of the DNA probe was hybridised to the RNA; its length is a measure for the distance between the *Mbo*II site and the 5′ terminus of the RNA or the beginning of extended mismatching between the RNA and the probe. As shown in Fig. 5*A*, natural rabbit β-globin mRNA protected a DNA fragment about 128 nucleotides in length; the DNA protected by RNA from β-globin transformed yeast cells gave five major bands, corresponding to 88, 91, 93, 102 and 110 nucleotides. The β-globin-specific transcripts from yeast apparently have several 5′ termini, all of which map downstream from the position corresponding to the 5′ terminus of natural β-globin mRNA. The 223-nucleotide band corresponds to the fully-protected probe and is believed to be due to self-annealing of the DNA; the presence of transcripts originating upstream, beyond the *Pst*I site, cannot be excluded.

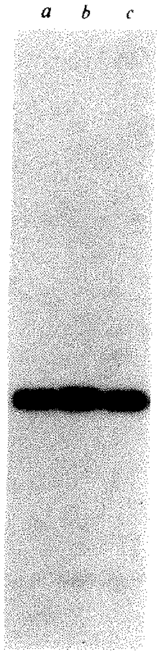

Fig. 3 Demonstration of β-globin-specific sequences in DNA from *S. cerevisiae* transformed with the β-globin DNA-containing hybrid plasmids YRβG-1 and YRβG-3. *S. cerevisiae* MC16αleu2-3 his4-712^{FS}ade2-1lys2-1SUF2 (G. R. Fink) was converted to spheroplasts and transformed with YRβG-1 and YRβG-3 DNA as described elsewhere[3]. Clones of transformed yeast were selected on plates lacking leucine[3]. One clone from each transformation experiment (Mc16/YRβG-1 and MC16/YRβG-3) was selected for further analysis. Transformed yeast was grown to late log phase in minimal medium without leucine (0.67% Difco yeast nitrogen base without amino acids, 2% glucose, 20 mg l^{-1} adenine, lysine and histidine). The cells were converted to spheroplasts[3] and DNA was isolated[27]. DNA was digested with *Pst*I and *Bgl*II simultaneously, subjected to electrophoresis through a 1% agarose gel in 40 mM Tris, 20 mM sodium acetate, 1 mM EDTA (*p*H 8.2) and transferred to a Millipore membrane[10]. Globin DNA sequences were detected by hybridisation with the cloned rabbit β-globin cDNA fragment described earlier[19], ^{32}P-labelled by nick-translation[28] (specific activity, 3.5 × 10^{7} c.p.m. μg^{-1}); (*a*) Z-pCRI/RchrβG-1, (*b*) YRβG-1 and (*c*) YRβG-3.

To determine whether the small intron was present in the β-globin transcript, a hybridisation experiment similar to the one above was carried out, using as probe the 4 kilobase-pair *Bam-Sal* fragment of Z-pCRI/RchrβG-1, labelled at the 5′ (minus strand) terminus of the *Bam* cleavage site. As shown in the scheme of Fig. 6, an RNA molecule lacking the small intron would protect the probe from the 5′-^{32}P-labelled *Bam* site to the position where the sequences of β-globin mRNA and chromosomal DNA no longer match (at the small intron), yielding a fragment of 212 nucleotides[7]. If the small intron were present, the probe would be protected up to the region corresponding to the 5′ end(s) of the transcripts, yielding fragments between 440 and 462 nucleotides. The autoradiogram of Fig. 6 shows the presence of a band at a position corresponding to about 440 nucleotides length, but no signal at the position corresponding to 212 nucleotides, proving that the small intron was present in the β-globin-specific transcripts.

Finally, the 3′ termini of the transcripts were mapped using the 14 kilobase-pair *Bam-Sal* fragment of the β-globin chromosomal DNA plasmid Z-pCRI/RchrβG-1 (ref. 6) labelled at the 3′ (minus strand) terminus of the *Bam* site. This probe was prepared by filling up the termini of the *Bam*-cleaved β-globin chromosomal plasmid with α-^{32}P-deoxynucleotides using DNA polymerase I, cleaving with *Sal*I and isolating the 14 kilobase-pair fragment. Preliminary experiments showed that despite hybridisation in 80% formamide, which disfavours DNA–DNA reannealing[17], a band corresponding to the full-length probe was found whether RNA was present or not. Therefore, to preclude protection of the labelled 3′ terminus by self-annealing, the *Bam* fragment was subjected to digestion with 5′λ exonuclease, sufficient to remove about 2,000 nucleotides, before cleavage with *Sal*I. Using this probe, hybridisation with RNA from yeast transformed with YRβG-1 and YRβG-3 yielded four major bands of 270, 295, 340 and 350 nucleotides (Fig. 5*B*). As the distance from the (filled-up) *Bam* site to the 5′ border of the large intron is 18 nucleotides, the majority of the β-globin transcripts extends to about the middle of the large intron. Because, an 18-nucleotide fragment could not be detected for authentic mRNA in the conditions of this experiment, we cannot exclude the possibility that some transcripts had undergone splicing; however, because most transcripts were 800–900 nucleotides long (see Fig. 4), spliced transcripts could only constitute a minority of the population.

To determine whether the β-globin-specific transcripts were polyadenylated, yeast RNA was fractionated on oligo(dT)-cellulose, and flow-through and retained fractions were assayed for the presence of globin-specific sequences either by the transfer procedure of Alwine *et al.*[11] or by the modified Berk–Sharp method[14]. The results were variable; even with the same RNA preparation in some experiments 30%, in others 70% of

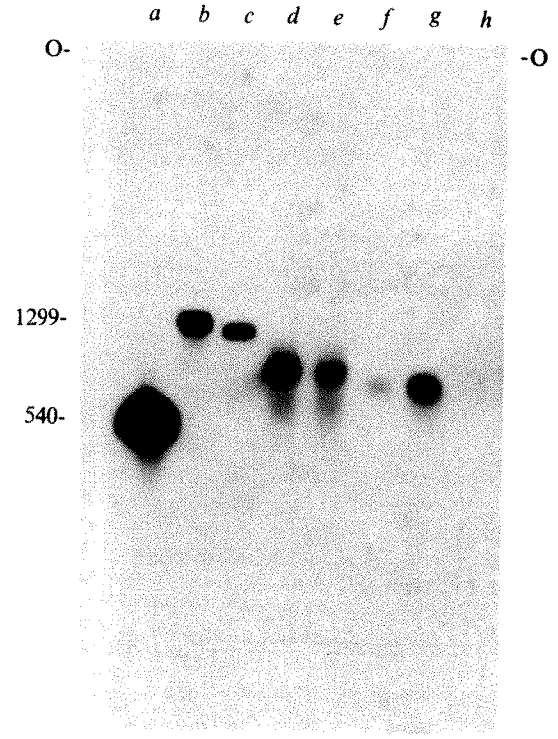

Fig. 4 The electrophoretic mobility of β-globin-specific RNA from *S. cerevisiae* transformed with the rabbit β-globin DNA-containing hybrid plasmid YRβG-1 and -3. *S. cerevisiae* was grown as described in the legend to Fig. 3. The cells were collected by centrifugation, washed in water, and suspended in 2 ml (per g of wet weight) 0.32 M sucrose, 20 mM Tris-HCl (*p*H 7.5), 10 mM EDTA containing heparin at 0.5 mg ml^{-1}. One volume of acid-washed glass beads was added and the sample was shaken on a vortex mixer for 1 min at top speed. The extract was diluted with 10 volumes 50 mM Tris-HCl (*p*H 7.5), 100 mM NaCl, 5 mM EDTA, 0.5 mg ml^{-1} heparin, 1% SDS, extracted with phenol and chloroform, and precipitated with ethanol. 24 μg RNA were recovered per ml culture. RNA samples were treated with glyoxal in dimethylsulphoxide at 50 °C for 60 min[29], subjected to electrophoresis through a 1.5% agarose gel in 10 mM sodium phosphate (*p*H 7), and transferred to diazobenzyloxymethyl paper[11]. β-Globin DNA-specific sequences were visualised by hybridisation in the conditions of Alwine *et al.*[11] with the cloned rabbit β-globin cDNA described earlier (ref. 19 and legend to Fig. 2), ^{32}P-labelled to 1.6 × 10^{8} c.p.m. μg^{-1} by nick translation with [α-^{32}P]dATP and [α-^{32}P]dCTP (400 Ci mmol^{-1} each, NEN). Denatured restriction fragments of rabbit β-globin-specific DNA and rabbit β-globin mRNA were used as size markers. *a*, Cloned rabbit β-globin cDNA[19]; *b* and *c*, plasmid Z-pCRI/RchrβG-1 digested with *Pst*I and *Bgl*II (1,299 base pairs) (*b*) or *Pvu*II and *Bgl*II (1,209 base pairs) (*c*); *d* and *e*, RNA from *S. cerevisiae* MC16 transformed with YRβG-1 (*d*) or YRβG-3 (*e*); *f* and *g*, rabbit (α + β) globin mRNA 2 ng (*f*) or 10 ng (*g*); *h*, RNA from *S. cerevisiae* MC16 transformed with pJDB219.

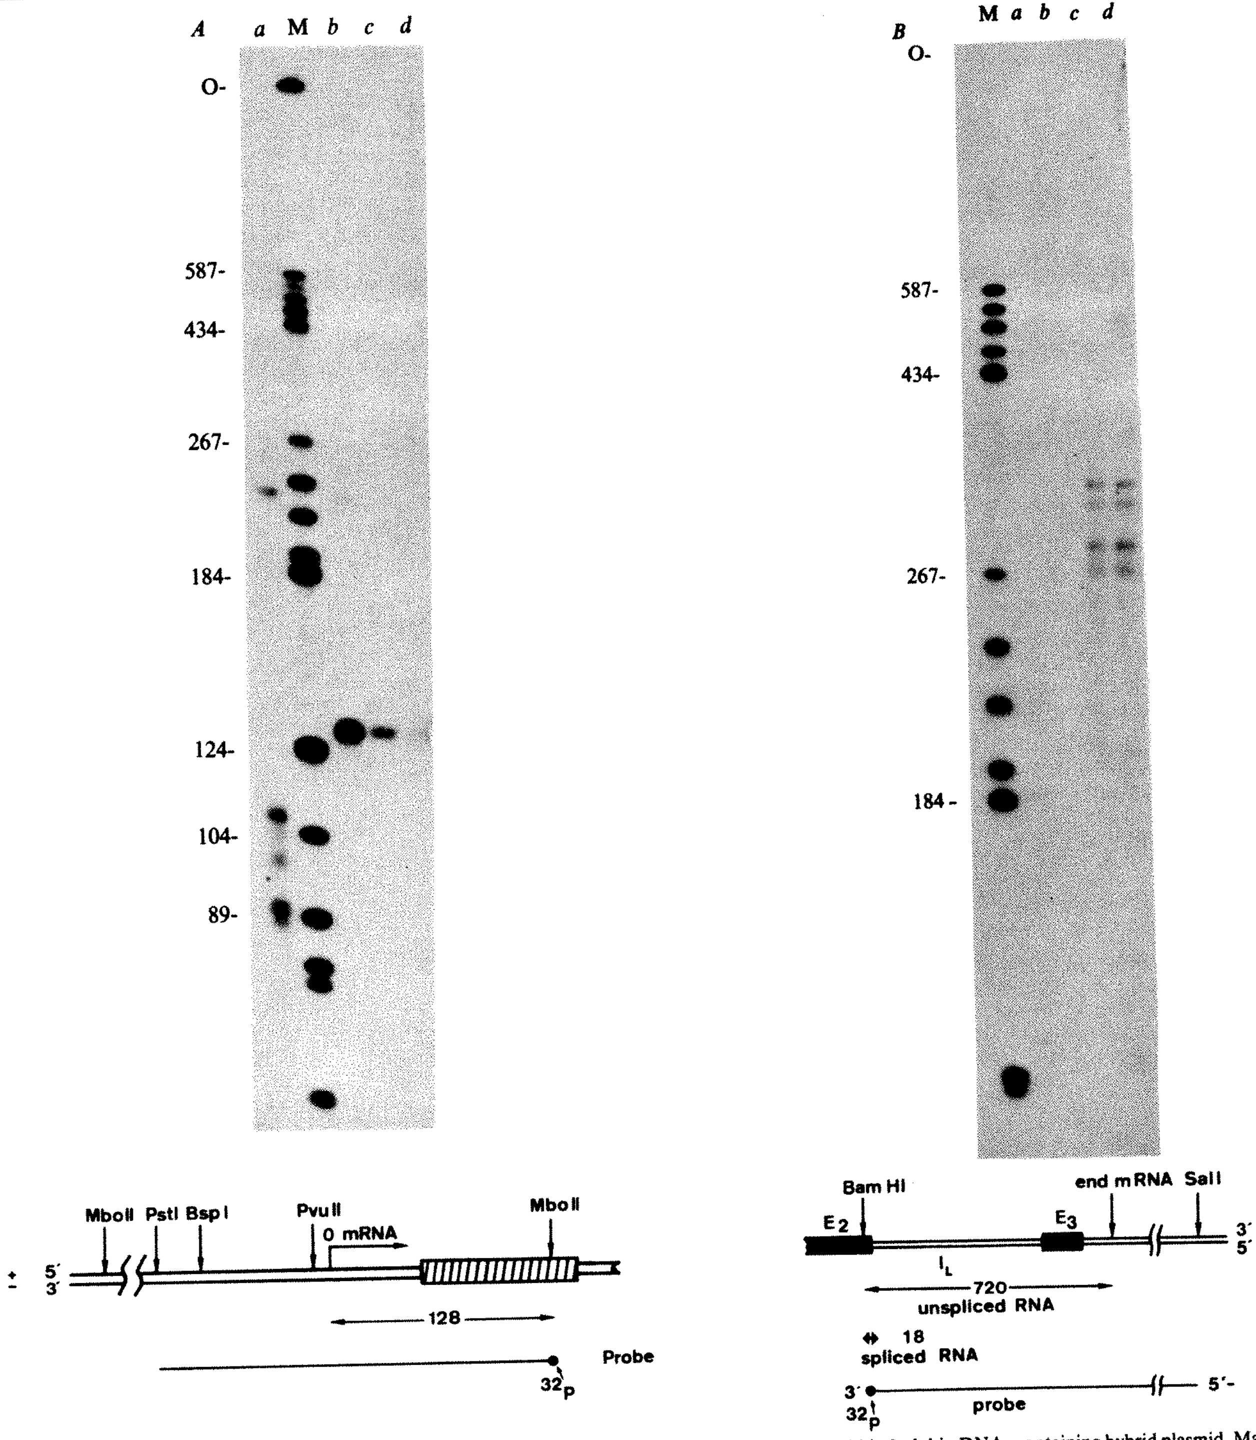

Fig. 5 Mapping of the termini of the β-globin-specific RNA from *S. cerevisiae* transformed with a rabbit β-globin DNA -containing hybrid plasmid. Mapping was carried out by a modification[14] of the Berk–Sharp[16] procedure. In this procedure a denatured, terminally ^{32}P-labelled DNA restriction fragment is hybridised to the RNA samples, treated with S_1 nuclease, and the length of the protected ^{32}P-labelled fragment is determined by polyacrylamide gel electrophoresis in 7 M urea. RNA from *S. cerevisiae* MC16/YRβG-1 was obtained as described in the legend to Fig. 4. *A*, Mapping of the 5′ termini. The DNA probe (see bottom section of figure) was prepared as follows. Plasmid Z-pCRI/RchrβG-1 was digested with *Hha*I, the 6.4 kilobase-pair fragment[6] isolated by sucrose gradient centrifugation, cleaved with *Mbo*II and 5′-terminally labelled with [γ-^{32}P]ATP[30] (specific activity, 3200 Ci mmol^{-1}). After cleavage with *Pst*I, the 223 base-pair fragment was isolated by electrophoresis through and extraction[14] from a 1.8% agarose gel in 89 mM Tris-borate (*p*H 8.2), 2.5 mM EDTA, ethidium bromide 1 μg ml^{-1}. The hybridisation reaction contained in 10 μl of 80% w/v formamide, 0.4 M NaCl, 0.04 M PIPES (*p*H 6.4), 1 mM EDTA, 11 ng denatured probe (about 7,000 d.p.m.) and RNA as indicated. Hybridisation was for 16 h at 57 °C under paraffin oil. The samples were digested with S_1 nuclease, extracted with phenol chloroform 1:1, and further processed as described elsewhere. Electrophoresis was in 89 mM Tris-borate (*p*H 8.2), 2.5 mM EDTA, 7 M urea on 5% polyacrylamide gels for 4 h at 700 V. Autoradiography was with use of Ilford fast tungstate intensifying screens, for 3 d at −70 °C. *a*, RNA (10 μg) from MC16 yeast transformed with YRβG-3; *b*–*d*, 3, 1 and 0.3 ng rabbit (α + β)-globin mRNA; M, marker (pBR322 cleaved with BspI and 5′-^{32}P-labelled). O, mRNA, position corresponding to origin of mRNA, hatched box, first segment of coding sequence. *B*, Mapping of the 3′ termini. The experiment is similar to that described above, but the probe was labelled at the 3′ terminus of the minus strand to permit downstream mapping (see bottom section of figure). Z-pCRI/RchrβG-1 (4 μg), cleaved with *Bam*HI, was incubated in 100 μl of 70 mM potassium phosphate buffer (*p*H 6.9), 100 mM NaCl, 5 mM $MgCl_2$ and 10 mM dithiothreitol with 3 units of DNA polymerase I (Boehringer Mannheim) and 5 μM each dTTP and dGTP, and 0.14 μM each [α-^{32}P]dATP and [α-^{32}P]dCTP (2 Ci mmol^{-1}, NEN) to label the 3′ termini. The labelled DNA was treated with *Sal*I and the larger (14 kilobase pairs) fragment, which contains the 3′ proximal segment of the β-globin DNA (and the ^{32}P-labelled minus strand 3′ terminus) was isolated by electrophoresis through a 0.7% agarose gel. To reduce the background resulting from self-annealing of the flush ends of the probe, the ^{32}P-labelled fragment (1 μg) was digested with 1 unit of 5′λ exonuclease[31,32] in 50 μl of 50 mM Na-cacodylate (*p*H 9.5), 5 mM $MgCl_2$, 50 mg ml^{-1} bovine serum albumen for 20 min at 23 °C. Each hybridisation assay (10 μl) contained 20 ng of denatured probe (20,000 c.p.m.) and RNA as indicated. The samples were processed as described above however, hybridisation was at 37 °C. Yeast RNA was prepared as described in the legend to Fig. 4. M, marker pBR322 cleaved with *Bsp*I and [5′-^{32}P]-labelled; *a* and *b*, 4 and 1 ng (α + β)-globin mRNA; *c* and *d*, RNA from *S. cerevisiae* MC16 transformed with YRβG-1 (*c*) or YRβG-3 (*d*). E_2 and E_3, second and third segments of coding sequence; I_L, large intervening sequence.

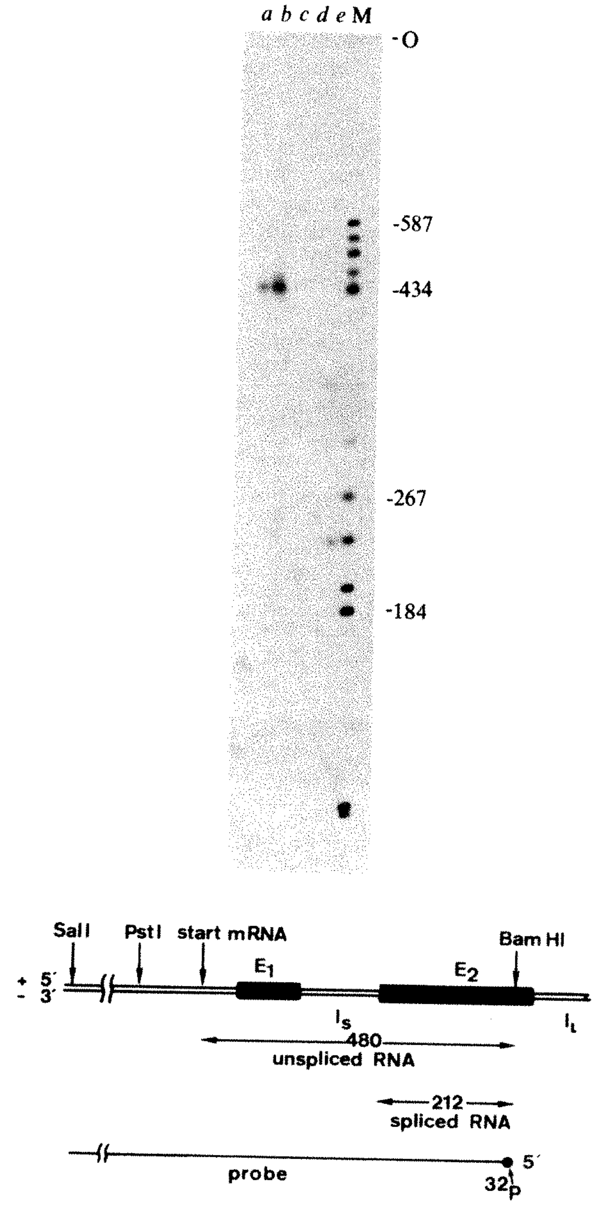

Fig. 6 Demonstration of the presence of the short intervening sequence in β-globin-specific transcripts from *S. cerevisiae* transformed with the rabbit β-globin DNA-containing hybrid plasmids YRβG-1 and YRβG-3. Mapping was carried out by the modified Berk–Sharp procedure[14] as outlined in the legend to Fig. 5 and the bottom part of this figure. Yeast RNA was prepared as described in the legend to Fig. 4. The DNA probe was prepared by cleaving Z-pCRI/RchrβG-1 with *Bam*HI, labelling the 5′ termini with [γ-^{32}P]ATP (3200 Ci mmol^{-1})[30] and cleaving with *Sal*I. The 4 kilobase-pair *Bam-Sal* fragment was isolated by electrophoresis through a 0.7% agarose gel. Hybridisation mixtures (10 µl) contained 50 ng of probe (20,000 c.p.m.) and RNA as indicated. The samples were processed as described in the legend to Fig. 5 and analysed by electrophoresis through a 3.5% polyacrylamide gel in 7 M urea. M, marker (pBR322 DNA cleaved with *Bsp*I and 5′ terminally ^{32}P-labelled); *a–c*, 10 µg RNA from *S. cerevisiae* MC16 transformed with YRβG-3 (*a*), YRβG-1 (*b*) and pJDB219 (*c*); *d* and *e*, rabbit ($\alpha+\beta$)-globin mRNA, 1 and 4 ng, respectively. E$_1$ and E$_2$, first and second segment of coding sequence; I$_s$, small intervening sequence.

Fig. 7 Approximate map positions of the 5′ and 3′ termini of rabbit β-globin transcripts in yeast. The nucleotide sequence and numbering are taken from Van Ooyen *et al.*[7]. Position 1 corresponds to the capped nucleotide. The 5′ and 3′ termini of the β-globin transcripts map in the areas indicated by black and open boxes, respectively. *a*, Sequences around the beginning of the β-globin gene. *b*, Sequences around the 5′ end of the large intron.

the globin-specific transcripts were in the retained fraction, in conditions where authentic β-globin mRNA was retained completely. This may mean that the chain length of poly(A), when present, was too short to ensure stable binding to the oligo(dT) column. A poly(A) tail of less than 15 nucleotides length appears to be insufficient to bind to oligo(dT)-cellulose[18].

Discussion

RNA from yeast cells transformed with the β-globin DNA-containing hybrid plasmids was intermediate in size between mature β-globin RNA and the 15S β-globin precursor. The β-globin-specific transcripts from yeast were about 20–40 nucleotides shorter at the 5′ end than normal globin mRNA (Fig. 7), contained the small intron and extended into the first half of the large intron where they terminated in an AT-rich region around the 250th to the 330th nucleotides of the large intron (Fig. 7), apparently heterogeneously and for the most part without a poly(A) appendage long enough to allow binding to oligo(dT)-cellulose. This should be considered in the light of the finding that the poly(A) tails of yeast mRNAs are on average considerably shorter than those of animal cell mRNAs; 50% of all yeast RNA molecules isolated on oligo(dT) cellulose have poly(A) chains less than 32 nucleotides in length[18]. It is not *a priori* certain that the 3′ and 5′ ends, as we have mapped them, correspond to the authentic termini of the transcripts. For one, the S$_1$ treatment may have trimmed the non-labelled end of the hybridised probe, particularly if it maps in an AT-rich region. However, S$_1$ digestions carried out in different conditions yielded similar patterns (R. Weaver, unpublished data) and thus do not support this hypothesis. Another possibility is that the primary transcript contained non-globin plasmid sequences at one or both ends and that a yeast-specific splicing reaction excised RNA segments comprising the junction to the globin sequence. The resulting structure would preclude detection of termini by the modified Berk–Sharp assay with a globin-specific probe. However, the length of the transcript, about 800–900 nucleotides, as estimated by its electrophoretic mobility, was in fairly good agreement with the length obtained by adding up the segments mapped upstream and downstream from the *Bam* site by the modified Berk–Sharp procedure, namely about 790 nucleotides, suggesting that no substantial segments of the transcripts escaped detection.

It is not clear whether the abnormal 5′ termini of the β-globin-specific RNAs from yeast represent transcription initiation sites recognised by a yeast RNA polymerase, or whether they result from the processing or degradation of longer transcripts originating at the true promoter site or even further upstream. Similarly, the 3′ termini may represent erroneous termination of transcription in T-rich regions or termini resulting from degradation or processing.

Why are the globin transcripts recovered from yeast not spliced? Possibly, yeast does not have a splicing system capable of processing the rabbit β-globin transcript. Alternatively, the transcripts and the appropriate splicing system are not present in the same compartment. Less likely, the β-globin transcript formed in yeast may not be susceptible to splicing because it lacks part of the 5′ terminal and more than a third of the 3′ proximal segment; perhaps a complete transcript is required to allow the formation of a secondary or tertiary structure essential for the splicing process.

In any event, the highly heterologous system we have described is obviously inadequate for the study of transcription and processing of the β-globin gene, which in more homologous systems, such as mouse L cells transformed with the rabbit β-globin gene[19], or monkey cells infected with β-globin–SV40 hybrid DNA[20,21] has proven capable of giving rise to normal β-globin mRNA.

We thank Dr R. Weaver for unpublished data and Mr W. Boll for carrying out the experiment shown in Fig. 5. The project was supported by grants of the Kanton of Zürich and the Schweizerische Nationalfonds (3.114.77) to C.W.; J.D.B. was the recipient of an EMBO short-term fellowship and a Beit Fellowship for Medical Research.

LETTERS

The composition of the Trojan asteroids

Jonathan Gradie & Joseph Veverka

Laboratory for Planetary Studies, Cornell University, Ithaca,
New York 14853

Physical studies have shown that most asteroids are covered with material of low visual albedo (p_v~0.04) having flat, nearly featureless reflection spectra between 0.4 and 1.1 µm (ref. 1). This large class of objects, the C asteroids, accounts for a progressively larger fraction of minor planets as one goes from the inner to the outer regions of the asteroid belt, a trend which has been interpreted as evidence of a decrease in effective condensation temperature in the original solar nebula with increasing distance from the proto-Sun[2]. We suggest here that the very low albedos and red spectra of some Trojan asteroids can be explained by the presence of kerogen-like organic compounds. Materials containing these types of carbonaceous substances, rather than those found in the more familiar carbonaceous chondrite matrix, may have been the primary rocky condensate in the outer Solar System and may therefore be typical of the rocky component of comet nuclei.

A widely accepted interpretation of these dark, spectrally neutral materials covering the asteroids, is that they consist of silicate clay minerals (montmorillonite, chlorite, serpentine) intermixed with opaque materials such as magnetite and finely divided carbon-rich compounds. Thus, the surface materials of the C asteroids are considered to be closely similar to, and in some cases perhaps identical with, the carbonaceous chondrite meteorites. Mixtures of small amounts of magnetite and carbon black with montmorillonite can be made to match both the albedo and the general spectral reflectance of some carbonaceous chondrites, although the carbonaceous matrix material in such meteorites is much more complicated in composition than carbon black[4,5]. The spectral reflectance curves (normalised at 0.56 µm) of the 115 km diameter C asteroid 141 Lumen, the C2 carbonaceous chondrite Murchison, and a carbonaceous construct are shown in Fig. 1.

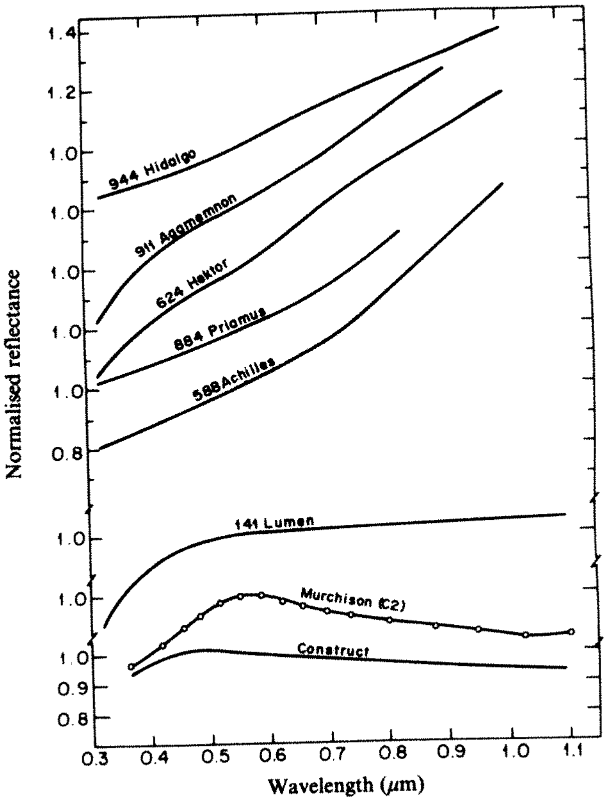

Fig. 1 Reflectance spectra of RD and C asteroids, the C2 carbonaceous chondrite Murchison, and a carbonaceous construct normalised at a wavelength of 0.56 µm. The construct is composed of 85% montmorillonite, 8% magnetite and 7% carbon (charcoal)[5]. The C asteroid is 141 Lumen. The RD asteroids are 588 Achilles, 624 Hektor ($p_v = 0.038$) and 911 Agamemnon ($p_v = 0.035$) in the preceding Trojan cloud, 994 Priamus of the following Trojan cloud and 944 Hidalgo[7]. Hidalgo is a unique asteroid in a comet-like orbit with a semimajor axis of 5.8 AU. Polarimetry and visual photometry suggest that Hidalgo may have a very low albedo[6].

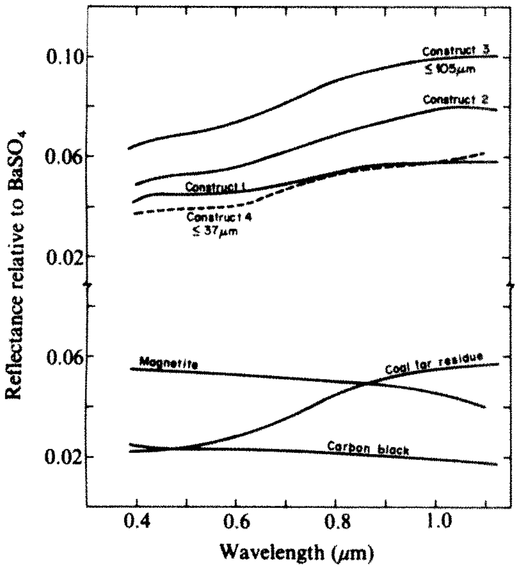

Fig. 2 The reflectances relative to $BaSO_4$ of several opaque substances and three carbonaceous constructs. Construct 1 is composed of 85% montmorillonite, 14.5% coal tar residue and 0.5% carbon black. Construct 2 is composed of 85% montmorillonite and 15% coal tar residue. Constructs 3 and 4 are composed of 85% montmorillonite, 7.5% magnetite and 7.5% coal tar residue. The particle size in constructs 1, 2 and 3 is ≤105 μm but ≤37 μm for construct 4.

However, there are low albedo asteroids which do not fit into the above scheme: some of the Trojan asteroids at two of the lagrangian points of Jupiter, some of the Hilda asteroids near the 2:3 commensurability with Jupiter, and the unusual asteroid 944 Hidalgo which has the second largest semi-major axis (5.8 AU) of any known minor planet. These objects have been labelled RD by Degewij and van Houten[6] as they are very dark ($p_v \sim 0.02$–0.04) and, unlike the neutrally grey C asteroids, are spectrally reddened between 0.4 and 1.1 μm. The normalised reflection spectra of several RD objects reported by Chapman and Gaffey[7] are shown in Fig. 1.

Degewij and van Houten[6] have suggested two possible compositions to explain this unique combination of low albedo and red colour: (1) a material similar to the calcium-rich angrite (visual reflectance ~0.055); and (2) following a suggestion from Gaffey, an iron-rich clay mineral similar to the matrix material of C1 and C2 carbonaceous chondrites but without the usual attendant opaque phases (magnetite and carbon-rich compounds). Both suggestions have difficulties. In the first, the connection with the angrite seems implausible as the single known angrite is classified with the eucrites as basaltic achondrites[8], which are the products of high-temperature processes that are unlikely to have occurred commonly in small bodies in the outer system. It is also difficult to resolve the absence in the RD spectra of the band near 1 μm prominent in the angrite spectrum. The second suggestion is simply incompatible with the extremely low visual geometric albedo of RD objects.

We propose that the nature of the RD objects can be explained better by the presence of very opaque, very red, polymer-type organic compounds, which are structurally similar to aromatic-type kerogen. Kerogen-like substances compose the bulk of the organic material in some carbonaceous chondrites[9]. These compounds probably result from non-biological processes in the early solar nebula—for example, materials from Fischer–Tropsch-type reactions between carbon monoxide and hydrogen at a few hundred degrees kelvin with iron metal, magnetite or silicate clay dust as possible catalysts may have been thermally altered to produce aromatic rich opaques[9–12].

Kerogen substances can be obtained by removing all solubles from ordinary coal tar. The spectral characteristics of the solubles have been investigated elsewhere[13]. The spectrum of the kerogen-like carbonaceous non-soluble residue left after dissolving coal tar in solutions of hexane, toluene and acetone measured with the Cornell goniometer is compared with those of carbon black and magnetite in Fig. 2. Of importance is the extremely low reflectance (0.02) of the coal tar residue in the visible compared to magnetite, and the strong increase in reflectance at the longer wavelengths compared with carbon black. Also shown in Fig. 2 are the spectra of various combinations of powdered montmorillonite, magnetite, the non-soluble residue from coal tar, and carbon black. Constructs 1, 2 and 3 are composed of grains ≤105 μm. Construct 4 is the same composition as construct 3 but composed of grains ≤37 μm. The decrease in reflectance with decreased grain size is opposite that observed for the clay minerals montmorillonite and chlorite[14] but can be explained by the extremely efficient coating ability of finely divided, opaque coal tar residue in a manner similar to that caused by submicrometer particles of lampblack. The normalised spectral reflectance curve of constructs 3 and 4 are compared with the normalised spectra of two RD asteroids in Fig. 3.

All constructs provide good matches to the observed photometric properties of the RD objects: low albedos and very red spectral reflectance curves. It is not necessary to postulate analogues of basaltic achondrites or opaque-poor clays. Mixtures of clays, magnetite, carbon black and an opaque, carbon-rich substance similar to terrestrial kerogen match the observed properties of RD asteroids and are cosmochemically likely to have been produced in the outer Solar System.

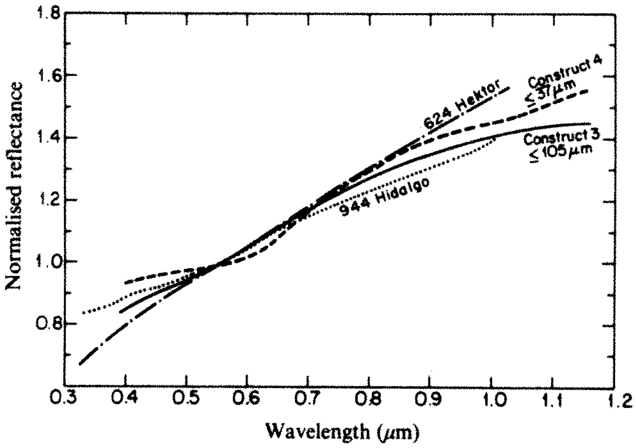

Fig. 3 The normalised reflectance of constructs 3 and 4 compared with two RD asteroids: 944 Hidalgo and 624 Hektor.

Our essential ingredient—the non-soluble residue—may have required lower temperatures for its formation and preservation than the carbonaceous materials in the carbonaceous chondrites and C asteroids. It is significant that a carbon-rich extract from the C3V meteorite Allende measured by Johnson and Fanale[4] has a spectrum unlike that of the non-soluble residue, but similar to that of carbon black, that is, the reflectance increases towards the shorter wavelengths and falls towards the IR. We suspect that the carbonaceous residue from Allende is not representative of the more primitive and unaltered carbon-rich material found in RD objects. This suggestion would explain why RD objects have not been detected closer than ~4 AU from the Sun, and implies that beyond the orbit of Jupiter RD material might replace C asteroid material as the typical condensate. If this suggestion is valid, the rocky material in comets should resemble RD material more closely than that found in the C asteroids.

We thank G. Sill, E. Suuberg for helpful suggestions, and L. Rozelle for computational assistance. This research was supported by NASA grant NSG 7606.

IR brightness and eclipse cooling of Saturn's rings

Equatorial scans of Saturn at 20 μm wavelength, obtained with the Mayall 4-m telescope in 1978–79, show a continuing decrease in the specific brightness of the A and B rings as the ring plane projection approaches an edge-on apparition. The decreased brightness of the previously dominant B ring reveals more clearly a large (~30%) difference in brightness between the east and west ansa portions of the C ring, in contrast to a barely discernible difference for the other ring ansae. The amount of eclipse cooling is compatible with a C ring particle size of ~1 cm. We propose here that the B ring brightness variation could partially result from a decrease of absorbed insolation by a modest amount of visible scattering.

Over the past few years we have monitored the 20 μm IR brightness of Saturn's rings with respect to the changing inclination of the ring plane toward the Sun (B'). During this time a large change in ring tilt has occurred. The ring plane attained its maximum tilt of about 26° in 1973 and will be edge-on in early 1980. On four occasions since March 1977 we have measured the ring brightness temperatures with the Kitt Peak National Observatory (KPNO) 4-m Mayall telescope and closed-cycle-cooler photometer system. The nominal 1 mm cold aperture in the focal plane produces a typical beamwidth (FWHM) of 2 arc s.

Figure 1 shows the equatorial scan obtained in January 1979 for a solar elevation angle relative to the ring plane (B') of −6.5°. A computer model fit to the scan is also shown. The model assumes a uniform brightness for each ring component and is more fully described elsewhere[1]. We have normalised the ring brightnesses relative to a disk centre temperature of 89.4±2 K, which assumes that the temperature has decreased by 0.5 K since our first March 1977 observation due to the 2% increase in Saturn's heliocentric distance. This correction assumes equal solar and internal heat sources[1–3].

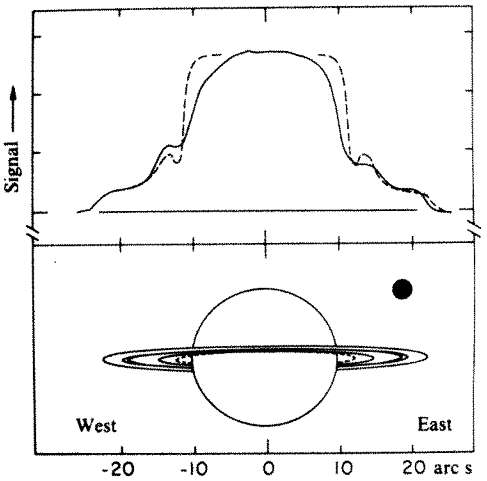

Fig. 1 Equatorial scan of Saturn at 19.7 μm and $B' = -6°.5$ obtained on 10–11 January 1979. The diameter (FWHM) of the telescope point source response function is shown by the cross-hatched circle. The dashed line shows the result of a two-dimensional convolution of the telescope function and the Saturn geometry which defines the ring brightness temperatures. In this calculation a uniform brightness temperature is assumed for each ring component so that the discrepancy between the model result (- - - -) and the experimental scan (——) at the C-ring ansae shows the difference attributed to eclipse cooling.

Comparing these results with our 1978 measurements confirms the pronounced difference in brightness between the east and west ansa positions of the C ring. The fact that a similar difference in brightness was evident in these data (see Fig. 1, ref. 4), when the larger ring inclination of ~12° excluded most of the B ring contribution to the beam at the C ring ansae positions, leads us to associate the observed brightness difference with the C ring. The brightness temperature for the east C ring ansa position is 81.5 K and for the west ansa 85 K, based on the above disk centre temperature of 89.4 K. The post-eclipse east ansa segment is 0.7 as bright as the corresponding west ansa segment.

Aumann and Kieffer[5] calculated particle size versus eclipse heating and cooling for possible ring materials. The observed amount of eclipse cooling, taking into account the ~2,000 s from eclipse exit to the east ansa orbit position, suggests a mean particle size of the order of 1 cm. The A and B rings do not show a significant brightness difference between the east and west ansa segments. Even allowing for the longer orbital periods in this case, the evidently much smaller eclipse cooling at the ansae would seem to exclude the same size composition for these rings. The C ring continues to show no decrease in brightness with respect to changing solar elevation, in contrast to the A and B rings[1].

Table 1 summarises the average ansa brightness temperature of the B ring over the observable range of ring inclination. In Fig. 2 these results are compared with three different ring models with respect to the B' dependence. While the multiple scattering model of Kawata and Irvine[6] is notable for its excellent match to

Table 1 20-μm brightness temperatures for the B-ring adjusted to a common heliocentric distance of 9 AU

visible observations, this model is incompatible with the observed B' dependence of the B-ring brightness at 20 μm.

The discovery of dark carbonaceous ring systems around Uranus and Jupiter led us to attempt to fit the B-ring brightness temperature with a simple two-component model consisting of dark particles sandwiched within a haze of small, icy particles. In this model the C ring is composed of dark particles alone, the less dense ice particles having been swept away by the Poynting–Robertson effect. Significant scattering of the visible solar insolation in the A and B ring occurs in the overlying layers of bright icy particles while the principal absorption and IR emission occurs in the embedded dark material. The dark material comes into thermal equilibrium with solar and planetary radiation components. The IR radiation in the direction of the Earth from the ring has three components: (1) the attenuated direct rays from the embedded dark particles; (2) the radiation scattered in the Earth direction by all points of the upper bright particle layer; and (3) the re-emission of radiation absorbed by the bright upper layer (the absorption of solar radiation by the bright layer is considered negligible).

In the calculation illustrated in Fig. 2, the solar constant is 17.2 W m^{-2} at 9 AU. A good fit is obtained for a total optical depth of 1 in the visible with the embedded dark layer having an optical depth of 0.90 and the bright particle layers over and underlying the dark particles an optical depth of 0.05 each. At 20 μm we assumed the same optical thickness for each layer as in the visible, and a single scattering particle albedo of 0.2 for the ice type particles. Finally, we assumed a constant thermal flux from Saturn of 3 W m^{-2} which accounts for the edge-on temperature limit of 70 K for zero inclination. The essential feature of this model is the scattering of visible solar insolation by a small particle fraction (~10%) of the total optical depth. The remaining specifications for a complete model would, of course, have to consider the optical and radar properties.

The experimental data can be equally well described by a $\sin^{1/4}|B'|$ dependence plus a constant planetary heating term equal to about 60 K. This is equivalent to an idealised Lambert surface which may represent the behaviour of a multi-layer particle model with certain simplifying assumptions according to Pollack[7]. Our most recent point for $\sin|B'| \cong 0.1$ suggests a possible inflection in the curve such as is seen in the two-component model result. Observationally it should be possible to obtain measureable ring signals for $\sin|B'|$ as small as 0.05. Such a measurement should be attempted in the latter part of 1980.

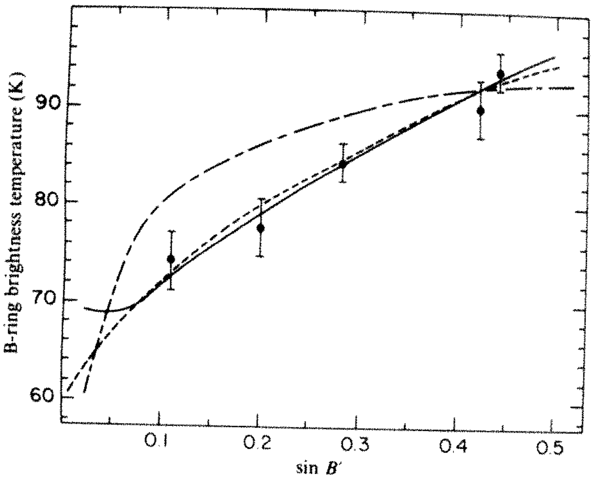

Fig. 2 The B ring brightness temperatures versus the sine of the solar elevation angle. The experimental data are given in Table 1. The three models compared here are: (1) ——, a two-component model discussed in the text; (2) - - - -, a $\sin^{1/4}|B'|$ plus constant dependence equivalent to Lambert type behaviour; and (3) — — — —, the results computed by Kawata and Irvine for a multiple-scattering model (their Model B).

The photoelectrochemical effect at a p-GaP electrode

J. F. McCann

Physics Department, The University of New South Wales, Kensington, NSW 2033, Australia

L. J. Handley

Chemistry Department, University of Texas at Austin, Austin, Texas 78712

Increasing attention is being focused on the properties and behaviour of p-type semiconductor electrodes. For instance, p-type GaP electrodes have been used in photoelectrochemical cells for water splitting[1], CO_2 reduction[2] and N_2 fixation[3]. We report here the quantum efficiency–potential characteristics for H_2 evolution at an irradiated p-GaP electrode. The curves have been evaluated using a Schottky barrier model of the semiconductor/electrolyte interface[4].

The H_2 evolution reaction at a p-type semiconductor electrode involves the transfer of photogenerated electrons from the conduction band edge (and via surface states) to H_3O^+ acceptor levels. For wide band gap non-corroding p-type semiconductors the H_2 evolution reaction is driven, in certain conditions, by a built-in overpotential (U_c) given by:

$$U_c = E_g - 1.23 - V_{sc}^{s-c} - \Delta E_F \qquad (1)$$

where E_g is the energy gap, V_{sc}^{s-c} is the potential drop across the space charge layer when the p-type semiconductor cathode is short-circuited to the anode and ΔE_F is the difference between the Fermi level and the valence band. An energy diagram of a p-type semiconductor/electrolyte/metal cell is shown in Fig. 1.

Solid state kinetics is favoured over electrochemical kinetics when U_c is large, which is frequently the case for wide band gap semiconductors. For p-GaP it was estimated that $U_c \sim 1.2$V. Therefore, for conditions which include low light intensities, sufficient cathodic bias and concentrated electrolyte it is appropriate to apply Schottky barrier theory to describe the quantum efficiency of H_2 evolution from a p-GaP electrode as a function of potential. According to this theory the quantum efficiency (η) is given by[4]:

$$\eta = 1 - \frac{\exp[-\alpha(\lambda) W_0 \Delta V_{sc}^{\frac{1}{2}}}{1 + \alpha(\lambda) L_n} \qquad (2)$$

where $\alpha(\lambda)$ is the absorption coefficient at a specified wavelength λ, W_0 is the space charge width for 1 V across the depletion layer, L_n is the electron diffusion length and ΔV_{sc} is the potential drop across the semiconductor space charge layer. The parameter ΔV_{sc} is the difference between the potential at the semiconductor surface and the flat band potential. The

0028-0836/80/090843—03$01.00

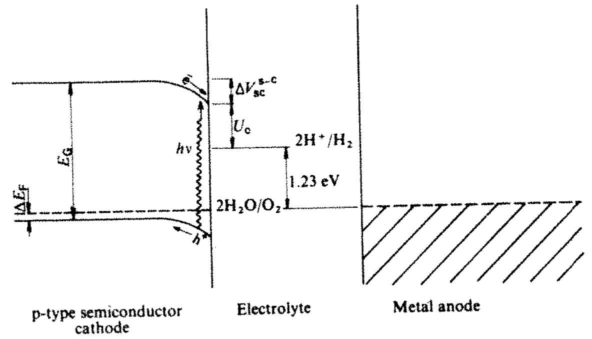

Fig. 1 Energy level diagram of a p-type semiconductor/electrolyte/metal system.

difference is proportional to the applied potential. For equilibrium short-circuit conditions ΔV_{sc} equals ΔV_{sc}^{s-c} in the absence of surface states.

An ohmic contact to a single crystal of p-type GaP (Zn doped; 111 face; $N_A \sim 2 \times 10^{16}\ \text{cm}^{-3}$; $\rho \sim 2\ \Omega\text{cm}$) was formed by soldering an In–Zn alloy onto the back of the sample. The crystal was then fabricated into an electrode by positioning it in a Teflon holder and fixing it with epoxy resin. Before the experiment the p-GaP electrode was etched in a HNO_3 : HCl (2 : 1) mixture for 2 min.

The cell p-GaP/1M NaOH/Pt was studied. Nitrogen was bubbled through the electrolyte for 20 min before the experiment. Monochromatic irradiation was obtained by passing polychromatic light from a 900 W xenon source through a high intensity Bausch and Lomb monochromator. Photocurrent-voltage curves were measured and recorded (potentiostatically) in the usual manner whilst irradiating the p-GaP electrode with light of wavelengths 4,400, 4,500 and 4,600 Å. Irradiation intensities were measured with a Zeiss thermopile model VT Q3/A. The quantum efficiency-voltage relationships were determined from the photocurrent-voltage curves using the expression:

$$\eta = \frac{i_{ph} - i_{dark}}{N_{ph}(O)} \equiv \frac{\text{No. of photoelectrons}}{\text{No. of incident photons}} \tag{3}$$

where i_{ph} and i_{dark} are the electrode current densities with and without illumination respectively.

Quantum efficiency-potential curves were calculated from the photocurrent-voltage curves at three different wavelengths (λ = 4,600, 4,500 and 4,400 Å). The $\alpha(\lambda)$s for GaP at these wavelengths were $< 5 \times 10^4\ \text{cm}^{-1}$. If $\alpha(\lambda) \gtrsim 10^5\ \text{cm}^{-1}$ surface recombination effects which become significant due to the high concentration of hole–electron pairs created close to the surface have to be taken into account in the expression for η.

Table 1 Parameters calculated from the quantum efficiency–voltage curve fitting analysis for irradiated p-GaP in 1M NaOH

Wave-length (Å)	(Photocurrent)^2 –flat band potential (V versus SCE)	$\alpha(\lambda)W_0$	Mean deviation (%)	$\alpha(\lambda)L_n$	Mean deviation (%)
4,400	−0.64	0.92	2.0	2.2×10^{-3}	1.8×10^3
4,500	−0.64	0.64	2.8	9.8×10^{-4}	1.0×10^3
4.600	−0.64	0.27	3.8	3.4×10^{-4}	1.0×10^3

Table 2 Comparison of the $\alpha(\lambda)W_0$ terms from curve fitting with $\alpha(\lambda)W_0$ terms calculated using $\alpha(\lambda)$s from ref. 6

Wavelength (Å)	$\alpha(\lambda)$ (cm^{-1}) (from ref. 6)	$\alpha(\lambda)W_0$* (using $\alpha(\lambda)$ from ref. 6)	$\alpha(\lambda)W_0$ (curve fitted values)
4,400	2.24×10^4	0.55	0.92
4,500	1.57×10^4	0.39	0.64
4,600	6.16×10^3	0.15	0.27

* W_0 was calculated as $2.47 \times 10^{-5}\ \text{cmV}^{-1}$ from equation (4) using $\varepsilon = 11$ (ref. 7).

Table 3 Comparison of the calculated and experimental ratios[6] of the absorption coefficients for p-GaP in 1M NaOH

Ratios	Experimental (from ref. 6)	Curve fitting
$\alpha(4{,}400\ \text{Å})W_0/\alpha(4{,}500\ \text{Å})W_0$	1.4	1.4
$\alpha(4{,}500\ \text{Å})W_0/\alpha(4{,}600\ \text{Å})W_0$	2.5	2.4
$\alpha(4{,}400\ \text{Å})W_0/\alpha(4{,}600\ \text{Å})W_0$	3.6	3.4

A nonlinear least-squares computer program was used to fit equation (2) to the experimental quantum efficiency–voltage curves. Two adjustable parameters, $\alpha(\lambda)W_0$ and $\alpha(\lambda)L_n$, and the flat band potentials determined from (photocurrent)^2–potential plots were used. Table 1 lists the flat band potentials and also the values determined for $\alpha(\lambda)W_0$ and $\alpha(\lambda)L_n$, from the least squares analysis of each curve together with the respective mean deviations of the latter parameters.

The experimental and theoretical quantum efficiency–voltage curves are shown in Fig. 2. The mean deviations of the $\alpha(\lambda)W_0$ terms were small (<4%) whilst those of the $\alpha(\lambda)L_n$ terms were large (~1,000%). The large uncertainties in the $\alpha(\lambda)L_n$ terms are due to the fact that their magnitudes are small in comparison to 1.0 which in turn means that their values cannot be determined accurately via a nonlinear least-squares fit of equation (2). Physically, the latter result implies that the contribution of electrons, photogenerated in the bulk region of the semiconductor, to η, is small.

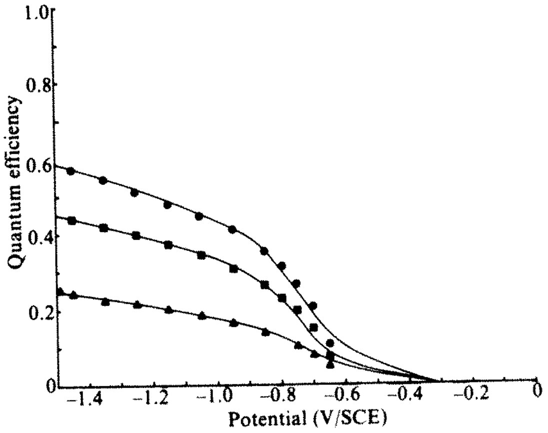

Fig. 2 Experimental (solid lines) and calculated (points) quantum efficiency versus voltage curves for p-GaP in 1M NaOH illuminated by 4,400 (●), 4,500 (■) and 4,600 (▲) Å light.

The parameter W_0 is defined by[4]:

$$W_0 = \left(\frac{2\varepsilon\varepsilon_0}{e_0 N_A}\right)^{1/2} \tag{4}$$

where ε_0 is the permittivity of a vacuum, e_0 is the electronic charge, ε is the semiconductor dielectric constant and N_A is the acceptor density. Table 2 lists the $\alpha(\lambda)W_0$ values obtained from the computer fitting with the $\alpha(\lambda)W_0$ values calculated using the $\alpha(\lambda)$s that have been reported previously for the respective wavelengths[6] and W_0 calculated from equation (4). The agreement between the $\alpha(\lambda)W_0$ terms calculated by the two different methods for each wavelength is satisfactory (within a factor of two) considering the uncertainty in the value of N_A.

A quantitative analysis of the $\alpha(\lambda)W_0$ terms (determined from the least squares fitting) consisted of comparing their ratios with the ratios of the p-GaP absorption coefficients for the respective wavelengths that have been reported previously[6].

The literature and computer fitted ratios are compared in Table 3 and the agreement is close (within 6%). Hence for the first time a quantitative correlation has been observed between the experimental quantum efficiency–potential curves for a p-GaP electrode and the respective fitted curves derived from a Schottky model of the semiconductor/electrolyte interface.

We thank Professor J. O'M. Bockris and Dr E. F. McCoy for helpful discussions.

Analogous Upper Proterozoic apparent polar wander loops

J. D. A. Piper

Department of Geophysics, University of Liverpool, PO Box 147,
Liverpool L69 3BX, UK

The ~1,100 Myr Grenville mobile belt of the Laurentian (North American) Shield yields a record of uplift magnetisations defining a closed apparent polar wander (APW) loop[1–4] nearly identical to the contemporaneous palaeomagnetic records from the Sveconorwegian belt of the Fennoscandian Shield and ~1,100–800 Myr supracrustal successions of the African Shield. The palaeomagnetic data reported here show that these Shields were contiguous at this time[4], and comparison with the pre-1,100 Myr palaeomagnetic record defines a relative rotation of the Fennoscandian Shield with respect to the other major shields at ~1,100 Myr, although they remained in close proximity until late Precambrian times. Tectonic and palaeomagnetic correlations between the major shields suggest that this motion represented an early fragmentation of rigid sialic crust. The restriction of crustal mobility to long linear mobile belts and the progressive contraction of anorogenic magmatism both define a gradual consolidation of the Proterozoic crust as temperature gradients declined.

Considerable attention has recently been devoted to determining the tectonic significance of palaeopoles from the Grenville Province[1–4]; a concerted evaluation has involved reconsideration of the Grenville palaeopoles in the context of the uplift and cooling history of this plutonic terrain[3,5], attempts to define the APW path from the remainder of the Shield during this interval[4,6], and isotopic studies using $^{40}Ar/^{39}Ar$ step heating determinations and diffusion characteristics to calculate both an age and synchronous temperature for minerals from the belt[7]. A relative chronology of the Grenville poles has been established using thermochron zones, which assumes that cooling and magnetisation of the belt followed the scheme defined by K–Ar mica ages; the mean poles defined by selected age intervals are illustrated in Fig. 1*a* (after ref. 2). They define the motion of APW as a closed loop although the age limits of the zones are regarded only as a first approximation to the ages of magnetisation[3,7]. Two more direct estimates by Berger *et al.*[7] use thermochronometry to estimate the ages of TRM components in the Haliburton intrusion (Hb_1 and Hb_3 in Fig. 1*a*) at ~980 and 820 Myr respectively.

The latest assessments agree that the Grenville loop represents an integral part of the total Laurentian APW path[3,4,7] and defines a post-1,030 Myr sequence which fits the sporadic coverage of the same interval from the remainder of the Shield[3,4]. Following refs 2 and 6 the earliest part of the Grenville loop in Fig. 1*a* is connected to a swathe defined by other poles dated 1,100–1,030 Myr. In addition, careful demagnetisation studies[6] have identified a time sequence of palaeopoles from the Jakobsville Formation (J_{1C}–J_{1SA} in Fig. 1*a*) which the authors suggest defines APW motion over the time interval 1,070–1.040 Myr. The youngest part of the Grenville loop also correlates with a range of palaeopoles from elsewhere in the Shield[3,6] although ages of magnetisation are poorly defined. Because most of the poles from the Grenville Province are

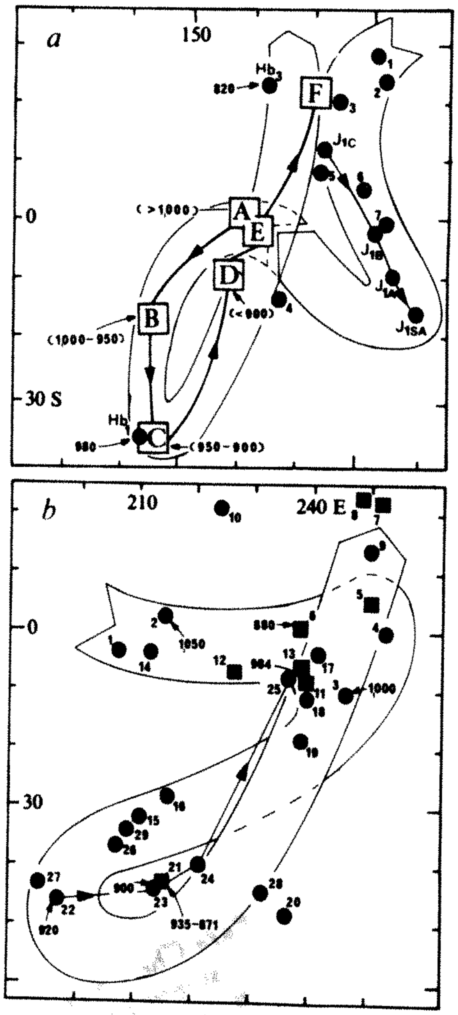

Fig. 1 Laurentian palaeomagnetic poles for the interval ~1,100–800 Myr. Numbered poles with ages in brackets are 1, Mamainse lavas, normal (1,070); 2, Portage Lake lavas (1,100); 3, Copper Harbour lavas (1,080); 4, Nankoweap Formation (1,000); 5, Freda and Nonsuch Sandstone (1,040); 6, Pikes Peak granite (1,030); 7, Cardenas lavas (1,090). JIC to JISA are the sequence of poles defined from the Jakobsville Formation[6]. The palaeomagnetic data from the Grenville Province are illustrated as mean poles A to F from thermochron zones and age assignments are a first order approximation only[2]; specific magnetisations Hb_1 and Hb_3 are dated by isotopic studies[7]. *b*, Fennoscandian 1,050–800 Myr palaeomagnetic poles (summarised in refs 9 and 10) derived from Sveconorwegian uplift magnetisations (●) and igneous intrusions into pre-Sveconorwegian terrain (■). Poles with age assignments in brackets are: 1, Bamble and Köngsberg metamorphic rocks (1,100–950 Myr); 2, Kragerö intrusions (1,050 Myr); 3, 4, Ålgon, Brattön norites; 5–10, Väby, Tärno (880 Myr), Bräkne-Hoby (975–880 Myr) Fäjö, Listed and Bolshavn dykes; 11, Nistrop sill (984 Myr); 12, Årby dyke (995 Myr); 13, Falun dyke (966–914 Myr); 14–18, intrusions in Sveconorwegian margin ('Schistosity') zone; 19, Tuve dyke; 20, SW Sweden amphibolites; 21, Karlshamn dyke (935–871 Myr); 22, Aana-Sira amphibolites; 23, 24, 25, Rogaland igneous complex A, B, C; 26, Egersund anorthosite: 27, 28 SW Norway farsundite; 29, Hunnedalen dykes (900 Myr.).

0028-0836/80/090845—03$01.00

derived from multicomponent magnetisations, uncertainties must surround both their precise position and their age[2]; also the link between the Jakobsville and Grenville poles is not, as yet, completely clear[6]. For these reasons it is not certain that the Grenville loop is anticlockwise (see refs 1, 4, 6, 7) as defined by the thermochron zones[2], and it is possible that polar trends over shorter periods were more complex. However, it is clear that the outward and return paths of the loop were very close together, and bearing in mind uncertainties in individual poles of 5–10° and a conventional APW swathe width of 15–20°, these points are not critical to the analysis that follows although they do impose limitations on the definition of the geological model.

The Sveconorwegian mobile belt of southern Norway and south-west Sweden[8] is a zone of medium-high grade plutonic rocks deformed at 1,100–1,000 Myr, and uplifted and cooled over a long interval after this. The palaeomagnetic data from this belt are shown in Fig. 1*b*. Insufficient K–Ar mineral ages are available to attempt a thermochron analysis[3,5] of these data, but we have the advantage of a contemporaneous body of data from dolerites intruded into cold crust of the adjacent (Svecofennian) zone and linked to Rb–Sr determinations[9]. Agreement with uplift magnetisations of the Sveconorwegian belt is close (Fig. 1*b*). The oldest part of the loop is defined by basement rocks of the Bamble and Köngsberg regions[10] with magnetisations linked to Rb–Sr and K–Ar studies[11] indicating an age of 1,050 Myr, and the base of the loop is linked to age dates in the range 935–900 Myr. The return path is defined in part by magnetisations of the Rogaland igneous complex[10,12,13] of which the latest phase is dated 842 Myr (ref. 14) and pole 25 is inferred to be somewhat younger than this[10].

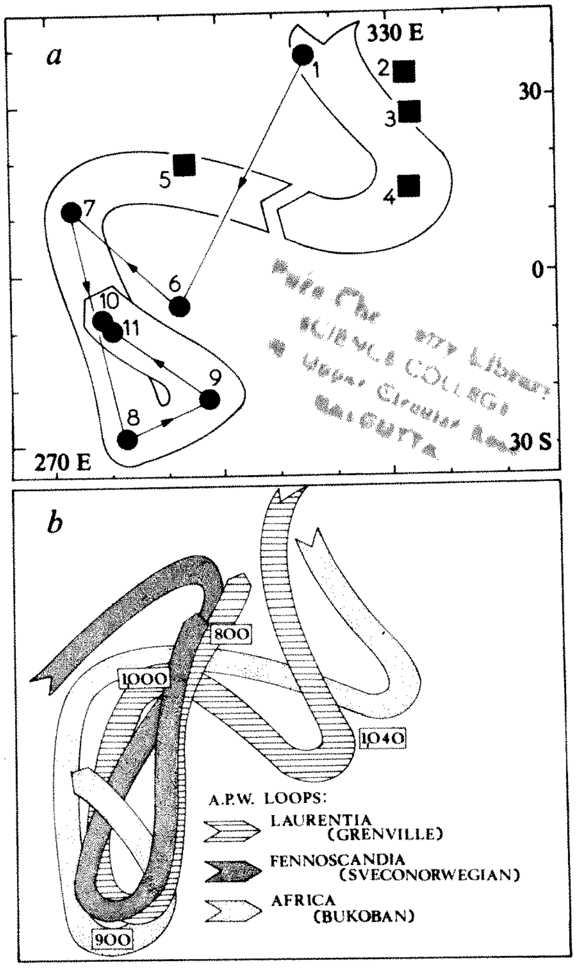

Fig. 2 *a*, African 1,050–800 Myr palaeomagnetic poles[5,15] from margins of the Tanganyika (●) and Kalahari (■) Shields with assigned ages in brackets: 1, Bukoba sandstone (1,000 Myr); 2, Chela sediments; 3, Nosib quartzite; 4, O'okiep intrusives (1,047 Myr); 5, Klein Karas dykes (>890 Myr); 6, Malagarasi sandstone; 7, Kigonero flags (900–1,000 Myr); 8, Gagwe lavas (818 Myr); 9, Manyovu red beds; 10, Moala dolerites; 11, Bukoban dolerites (811 Myr). The dashed line connects the sequence of poles defined from the stratigraphic succession of the Bukoban System; there is overlap between 95% confidence ovals of some of these poles. For pre-1,040 Myr data see ref. 25. *b*, Comparison in size and shape of the three APW loops.

The contemporaneous APW path for Africa is currently less well defined, but is of comparative interest because the data are derived from supracrustal sedimentary/volcanic suites. A loop here is defined by a stratigraphically controlled sequence of poles from the 1,000–800 Myr Bukoban System of Tanzania (ref. 15, Fig. 2*a*) and limited data from southwestern Africa[5,15].

We observe that the 1,050–800 Myr palaeopoles from each of these Precambrian Shields define a flattened APW loop of comparable chronology, size and shape (Fig. 2*b*). The similarity is so close that identical polar movement seems to be recorded relative to each shield; critical points in the correlation are the 1,000–900 Myr and 900–800 Myr links of the Laurentian and Fennoscandian paths and the 1,100–1,040–1,000 Myr arms of the African and Laurentian paths. The principal remaining problem with direct correlation is the distribution of age estimates for the base of the loop ranging from a maximum of 980 Myr from the high blocking temperature component of the Haliburton intrusion[7] to a minimum of 820 Myr for the Gagwe lavas[15]; the latter is a K–Ar determination on lavas exhibiting advanced stages of hydrothermal alteration and is likely to be on the low side.

The tectonic significance of these loops is that when superimposed they yield a reconstruction with the Shields in direct continuity (Fig. 3*b*). The existence of the African–Laurentian link before 1,100 Myr is supported by a range of palaeomagnetic and tectonic evidence[16], and although this link has been disputed[17], I have argued elsewhere that the case rests on an oversimplification of the palaeomagnetic record for the Laurentian Shield[18]. The Laurentian–Fennoscandian configuration however, cannot be reconciled with the pre-1,200 Myr data[16,19,20] which support a contiguous configuration but with the Sveconorwegian and Grenville belts in close alignment (Fig. 3*a*)[20]. This relative motion of the Fennoscandian and African–Laurentian Shields is further indicated by the convergence of their separate APW paths in the correlation of Fig. 2*b*, and the net motion is a clockwise rotation (~110°) of the Fennoscandian Shield about a local axis of rotation in the Baltic Sea.

Whether or not this net rotation was the only motion involved cannot be decided at present because of the paucity of Fennoscandian data relating to the interval of motion (~1,200–1,000 Myr). However, it seems likely that rupture and re-impingement of the two Shields involved some strike-slip motions because there is consistent evidence for dextral motion along the Grenville Front between 1,200 and 1,000 Myr in the form of deformation and displacement of the Labrador Trough[2] and opening of the Keweenawan rift system[21,22]. Impingement of the two shields in a new configuration could account for this large regional stress system, and it also produced crustal thickening of the mobilised continental margins represented by the Grenville and Svecornorwegian belts[2,23]. Direct consequences of this thickening were the extensive intrusion of large anorthosite, gabbro, and related plutons and the protracted crustal uplift[24]; the Grenville Front and 'Schistosity Zone' (the latter separating the Sveconorwegian belt from the previously-stabilised sector of the Fennoscandian Shield) define the abrupt limits of this remobilised terrain. Note also in Fig. 2*b* that there is slight mismatch between the pre- and post-1,000 Myr segments of the African and Laurentian APW curves; this might simply reflect the poor control of the African curve, but may also be interpreted in the context of relative (sinistral) motion between the two Shields at about this time.

Does this fracturing and rotation of the Fennoscandian Shield

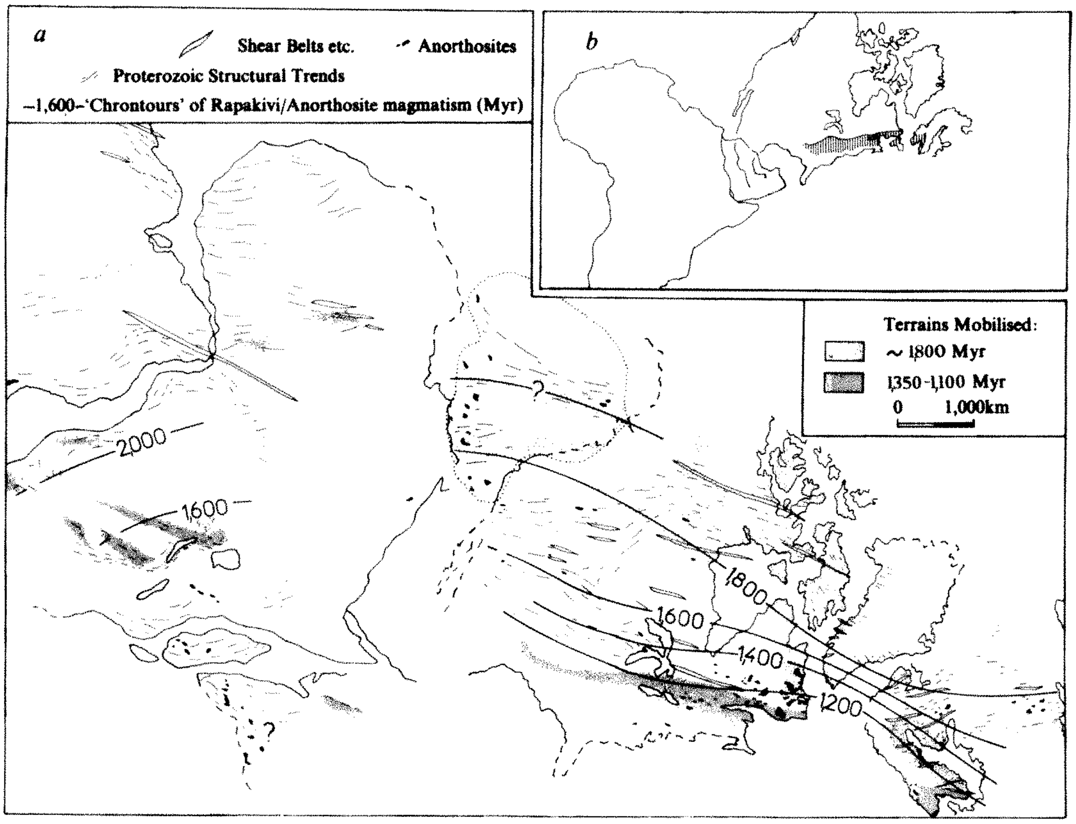

Fig. 3 *a*, The distribution of some of the major shields in Middle Proterozoic times after refs 20, 25, 26 compared with the reconstruction (*b*) derived by superimposing the three 1,050–800 Myr APW loops of Figs 1 and 2. The configuration of the Siberian Shield in *a* is that proposed by Sears and Price[36]; present palaeomagnetic data are not in conflict with this reconstruction[26] but are not yet suitable for a definitive test. The distribution of some major geological features formed between ~2,700 and 1,100 Myr is plotted on *a*, and the chrontours define the approximate time of termination of anorogenic intrusive magmatism belonging to the massive anorthosite/rapakivi granite suite.

at ~1,100 Myr represent the earliest phase in disruption of a consolidating Proterozoic crust? Present palaeomagnetic data bearing on this point are equivocal, although they are consistent with a single configuration of the Fennoscandian and Laurentian Shields to at least 1,700 Myr (refs 25, 26) (and the African and Laurentian Shields to at least 2,100 Myr (ref. 25). There is, however, a strong geological case to suggest that the crustal distribution of Fig. 3*a* represents the approximate form of the continental crust before ~1,100 Myr (the Australian sector of Gondwanaland is omitted from this diagram because relative motions before the Lower Palaeozoic[27] leave uncertainties about its relationship to the other shields). This evidence includes the general alignment of Lower Proterozoic structural trends, mylonite and strike-slip zones[26,26–30] and the pattern of the Rapakivi-massive anorthosite intrusive activity. Conditions appropriate[31] to this anorogenic magmatism, widespread in early Proterozoic times, became progressively more restricted within the zones regenerated during the widespread ~1,800 Myr mobile activity (ref. 32 and Fig. 3*a*) with a gradual restriction to one margin of the Fennoscandian–Laurentian Shield; intrusion ceased altogether at about 1,000 Myr. Figure 3 shows 'chrontours' (based mainly on age data compilations discussed in refs 32 and 26) to describe the contraction of this magmatism across the Proterozoic crust. These appear to reflect declining temperature gradients as this crustal unit cooled so that conditions were no longer appropriate to the high level intrusion of large anorogenic bodies; a comparable trend seems to be present across the African Shield (Fig. 3*a*), although the data points here are too few to be sure of this.

The intrusion of anorogenic bodies persisted longest near the Grenville and Sveconorwegian mobile belts. These and other belts formed during the episode of mobile activity at 1,350–1,100 Myr (ref. 33) tend to form linear and relatively narrow zones separated b sharp structural and/or thermal contacts from adjoining terrains; they are probably more widespread than originally suspected within the African Shield[34]. Their alignment along a great circle trend[16] in the pre-1,100 Myr reconstruction (Fig. 3*a*) began to be dismembered by the post-1,100 Myr motions (Fig. 3b)).

Therefore, the initial break-up of the sialic crust apparently followed closely on the decline of temperature gradients defined by the stage at which anorogenic magmatism could no longer take place outside narrow zones of crustal mobility. This stage is also represented by transcontinental brittle fracturing during the Mackenzie–Sudbury–Gardar–Jotnian igneous episode at ~1,200 Myr (ref. 20). The transition to the scheme of plate tectonics characteristic of Phanerozoic times was, however, a gradual one because ensialic zones of crustal mobility were still developing within the African Shield at 700–500 Myr (ref. 35).

I thank J. E. F. Stearn for discussions on Sveconorwegian palaeomagnetism. Precambrian palaeomagnetic studies are supported by NERC grant GR3/2398.

Oxygen isotopic-hydrographic relationships among recent planktonic Foraminifera from the Indian Ocean

Douglas F. Williams & Nancy Healy-Williams

Department of Geology and Belle W. Baruch Institute for Marine Biology and Coastal Research, University of South Carolina, Columbia, South Carolina 29208

The stable isotopic composition of fossil Foraminifera has become an increasingly important tool in palaeoecological and stratigraphic studies of marine sediments[1-3], prompting several studies of the factors governing the isotopic composition of living and recent Foraminifera. Many studies have documented the good agreement between the inferred depth of growth from oxygen isotopic data[4-8] and the depth stratification found in plankton tows[9-11]. Although results have suggested disequilibrium in some species[12-14], especially among the benthic species[15,16], recent data from Sargasso Sea plankton tows[17-19] and Indian Ocean core top sediments[20,21] suggest that oxygen isotopic equilibrium is nearly achieved in many ecologically important species. In the present study, oxygen isotopic data on as many as eight species and subspecies of planktonic Foraminifera from 52 Indian Ocean core top samples permit a comprehensive comparison of the isotopic–temperature trends across the major oceanographic regions of the Indian Ocean (Table 1). Several shallow-dwelling species (*Globigerinoides ruber*, *G. sacculifer* and *Orbulina universa*) were used as a measure of the upper 50–100 m of the water column (the mixed surface layer). Several deep-dwelling species (*G. truncatulinoides* (left and right coiling varieties), *G. inflata*, *G. scitula* and *G. hirsuta*) were used for comparison with hydrographic data from 200 to 300 m depths. The results show that the isotopic difference between the shallow and deep-dwelling species is directly related to the temperature difference between the surface waters and the depth of the permanent thermocline. This isotopic–temperature relationship suggests that isotopic analyses of species which inhabit different water depths may be used to determine the thermal gradient in the upper water column during the Cenozoic.

The foraminiferal δ^{18}O data are from four sources: widely distributed core tops from Williams[8] and Prell *et al.*[22]; Arabian Sea and Bay of Bengal core tops from Duplessy[23]; and core tops from the southwestern Indian Ocean by Shackleton and Vincent[24]. Temperature and salinity data were obtained for each core top location from the Indian Ocean atlas of Wyrtki[25] and surface temperature maps compiled by the Geophysical Fluid Dynamics Laboratory[26] (Table 1). The salinity–δ^{18}O relationship for Indian Ocean waters was used to estimate the isotopic composition of seawater[27]. The isotopic equilibrium relationship of inorganically precipitated calcite[28] was used to estimate the δ^{18}O of calcite precipitated in isotopic equilibrium at ambient seawater conditions. Linear regression analyses were then used to compare the foraminiferal isotopic data against surface water temperature, and the δ^{18}O of equilibrium calcite at 0, 200 and 300 m.

Strong linear correlations exist between the δ^{18}O of the shallow dwelling species, surface-water temperature and estimated δ^{18}O values for equilibrium calcite at surface conditions (Fig. 1; Table 2). The isotopic composition of the three mixed surface layer species shows depleted values at warmer water temperatures and a steady enrichment at colder temperatures. Individually, the δ^{18}O of *G. ruber* and *O. universa* have the best fit with average surface temperature ($r = -0.89$ and -0.91). Collectively, the δ^{18}O values of all three species have an equally strong correlation with average surface temperature ($r = -0.89$). The slope and intercept of the regression equations are almost identical to those based on equilibrium calcite values and temperature at the same locations (Table 2). The differences in slope and intercept of the regression results for each species (Table 2) reflect the slight differences in calcification temperature due either to seasonal growth or to small depth habitat differences within the mixed surface layer.

Over the same latitudinal and temperature range, however, the isotopic composition of the deep-dwelling *Globorotalia* species shows very little systematic change (Fig. 1). North of the Subtropical Convergence (STC) zone (38°–42° S) the δ^{18}O–temperature gradient for the four *Globorotalia* species together ($r = -0.53$) is 0.05‰ °C^{-1}, <30% of the gradient exhibited in the shallow species and equilibrium calcite. The oxygen isotopic composition of *G. inflata* and *G. truncatulinoides* has a poor correlation with surface temperature ($r = -0.54$ and -0.62). Assuming isotopic equilibrium, calcification among the *Globorotalia* group north of the STC seems to occur at the base of the seasonal thermocline between 200 and 300 m on the basis of estimated δ^{18}O values for equilibrium calcite at these depths (Fig. 1). South of the STC, the δ^{18} of the *Globorotalia* species becomes significantly correlated with surface temperature ($r = -0.89$) with an increase in the δ^{18}-temperature gradient to 0.13‰ °C^{-1} (Fig. 1; Table 2). Individually, *G. truncatulinoides* and *G. inflata* specimens south of the STC exhibit equally strong correlations between their isotopic composition and temperature ($r = -0.93$ and -0.97) (Table 2).

These isotopic trends among the shallow and deep dwelling foraminiferal species have an oceanographic explanation which has important implications for future palaeoceanographic studies. In northern subtropical, equatorial and southern subtropical waters where a steep thermocline exists either year-round or seasonally, the temperature dependent isotopic difference between the deep and shallow dwelling species ($\Delta^{18}\text{O} = \delta^{18}\text{O deep} - \delta^{18}\text{O shallow}$) is large and varies between 3.7 and 1.5‰ (Figs 1 and 2). Δ^{18}O undergoes a systematic decrease toward higher latitudes and decreasing surface water temperature, mirroring the change in the temperature gradient between the surface and depth of the permanent thermocline. At the STC zone, where southern subtropical and northern subantarctic surface water masses converge, Δ^{18}O reaches a minimum of <1‰, corresponding to the region where the thermocline has a minimal thermal gradient. In the subantarctic, Δ^{18}O remains at a minimum, reflecting the lack of a temperature difference between either the season of growth or depth of growth of the deep and shallow species of this region. The same basic Δ^{18}O–temperature relationship exists if the isotopic difference between the *Globorotalia* group and *G. ruber*, or *G. truncatulinoides* and *G. ruber.* is used (Fig. 2).

By calibrating these systematic isotopic differences between pelagic species which inhabit the mixed surface layer and the upper permanent thermocline, the isotopic difference between the average δ^{18}O values of the shallow species and deep *Globorotalia* species could be used to provide an average measure of the temperature difference between the mixed layer and permanent thermocline during different climatic and glaciological states. Likewise, the isotopic difference between a single shallow species (*G. ruber*) and deep species (*G. truncatulinoides*) which have overlapping geographic ranges, could also be utilised. Although all three of the Δ^{18}O–temperature relationships are strongly linear (Table 3), the best fit lines are not parallel but converge towards lower temperatures (Fig. 2). At a temperature maximum of 28 °C, the Δ^{18}O–temperature equations differ by only ±0.25‰ (1 s.d.), which is equivalent to a temperature difference of ±1.2 °C (1 s.d.). An estimated error in the Δ^{18}O (deep–shallow) equation of ±0.33‰ (±1.65 °C) is obtained by comparing observed and estimated Δ^{18}O values. Although more time consuming, the use of an average isotopic

0028-0836/80/090848—05$01.00

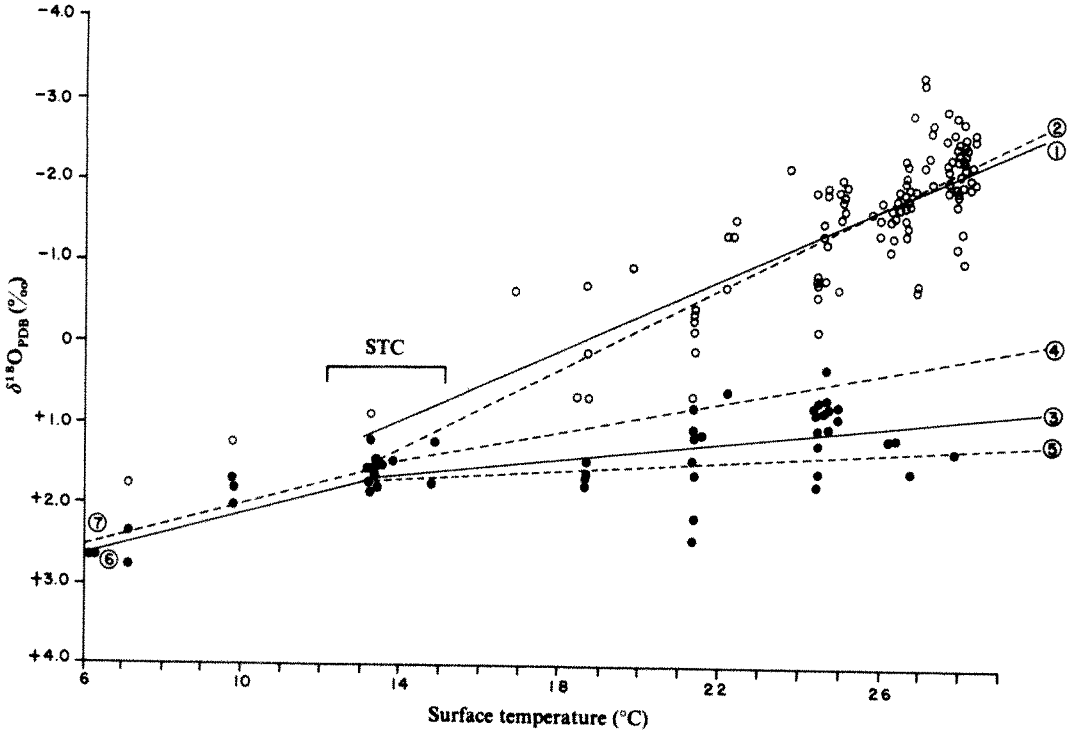

Fig. 1 Linear regression results comparing the $\delta^{18}O$ of the shallow (○) species (*G. ruber, G. sacculifer, O. universa*) and deep (●) species (*G. truncatulinoides, G. inflata, G. hirsuta, G. scitula*) to average surface-water temperature in the Indian Ocean. The temperature range of the subtropical convergence zone (STC) is indicated. The solid lines 1, 3, and 6 represent the best fit lines for all shallow species, all deep species north of the STC, and all deep species south of the STC, respectively (Table 2). The dashed lines represent the best fit lines for equilibrium calcite at 0 m (2), 200 m (4, north of the STC; 7, south of the STC) and 300 m (5, north of the STC) (Table 2). The size fraction of the foraminiferal specimens varied from >63 μm (ref. 24) to >150 μm (refs 8, 22, 23). The isotopic differences between different size fractions of the same species[33,34] probably add to the scatter in the data but do not detract from the results of this study.

Other essential aspects of the analytical techniques were the same in generating the isotopic data: monospecific foraminiferal calcite samples were reacted *in vacuo* in purified phosphoric acid after roasting *in vacuo* for 1 h. The evolved CO_2 gas was purified of water vapour and analysed in a VG Micromass 602 mass spectrometer. All are reported in the conventional δ notation as the ‰ enrichment or depletion in ^{18}O relative to the PDB standard[35]. Detailed analytical procedures can be found in Shackleton and Opdyke[36], Williams *et al.*[37] and Duplessy[23]. Oxygen isotope stratigraphy was used to validate the age of nearly all the core top samples as Recent or late Holocene.

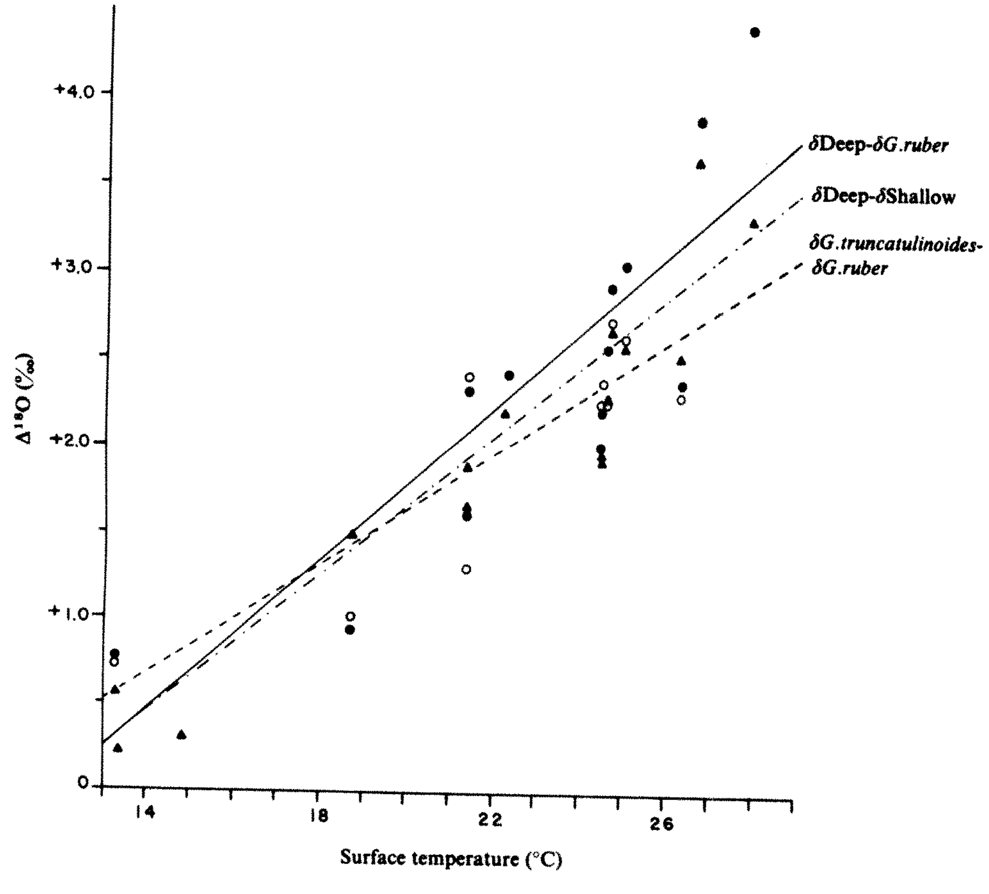

Fig. 2 Linear regression results comparing the oxygen isotopic difference ($\Delta^{18}O$) of average deep – shallow group (▲), average deep group – *G. ruber* (●), and *G. truncatulinoides – G. ruber* (○) with surface water temperature. See Table 3 for exact equations.

composition for the deep and shallow group would have the advantage of minimising preferential biasing of the isotopic record by bioturbation effects on a single species which undergoes changing relative abundances through short-term climatic cycles[29].

In addition, the results of this study show that the change in the latitudinal $\Delta^{18}O$–temperature gradient in *G. truncatulinoides* and *G. inflata* north and south of the STC can be used to detect changes in the past positions of water mass boundaries such as the STC (the $\delta^{18}O$ of *G. truncatulinoides* changes from 0.06 to 0.12‰ °C^{-1} and the $\delta^{18}O$ of *G. inflata* changes from 0.04 to 0.19‰ °C^{-1} north and south of the STC, respectively). In fossil assemblages where *G. truncatulinoides* is rare or absent, other abundant deep dwelling species such as *G. inflata* may be substituted. South of the STC, the $\delta^{18}O$–temperature best fit line for all the deep dwelling species parallels the best fit lines for equilibrium calcite at both the surface and 200 m.

The $\Delta^{18}O$ trends in the Indian Ocean surface sediments strongly suggest that seasonality may also be recorded in the isotopic composition of fossil assemblages. Results of an isotopic study of living *G. ruber* and *G. truncatulinoides* collected seasonally in the Sargasso Sea[17] have shown that the observed isotopic difference ($\Delta^{18}O$) between *G. ruber* during the summer temperature maximum and *G. truncatulinoides* during the winter temperature minimum ($\Delta^{18}O = 2.0‰$) agrees remarkably well with the estimated $\Delta^{18}O$ of 2.18‰. This estimated $\Delta^{18}O$ value was obtained by extrapolating the average surface temperature at the Sargasso Sea location (23.4 °C) to the $\Delta^{18}O$–temperature relationship for *G. truncatulinoides* and *G. ruber* in the Indian Ocean (Fig. 2). These results suggest that the isotopic composition of certain planktonic foraminiferal species is both a function of depth habitat (particularly in equatorial regions where little seasonal change in the thermocline occurs) and seasonal occurrence.

Of course, to use the modern interglacial $\Delta^{18}O$ relationship to estimate absolute sea-surface temperatures during the Pleistocene, it must be assumed that the deep dwelling species maintain approximately the same mean calcification temperature during glacial times. The near constant isotopic composition of *Globorotalia* species from such widely different oceanographic regions as the Arabian Sea to the Subtropical Convergence suggests that this assumption may be reasonable. It has already been shown that surface isotherms during the last glacial maximum can be reconstructed using the isotopic composition of *G. sacculifer* at equivalent levels in piston cores[30]. It may therefore be possible to map the geographic distribution of $\Delta^{18}O$ at different times to determine the changes in the thermal gradient of the upper water column and to provide a comparison with sea-surface temperature estimates based on micropalaeontological transfer functions[31,32]. In addition, the correspondence between the $\Delta^{18}O$ trend in surface sediments of the Indian Ocean and the seasonal temperature–isotopic relationship in the Sargasso Sea suggests that the seasonality of a region may be decipherable from isotopic studies of multiple species from fossil assemblages.

Table 2 Linear regression analyses of foraminiferal isotopic composition versus water temperature

$\delta^{18}O$*	Surface temperature†	Correlation coefficient	Least squares equations
G. ruber	0 m	−0.89	$\delta^{18}O = 5.48 - 0.28T$

Foraminifera are separated systematically at the subordinal and suprafamilial level on the basis of their wall ultrastructure[1], yet those elements of the walls are near or at the resolution of the optical microscope[2]. To delineate those elements we have initiated a comprehensive study of the test ultrastructure of calcareous Foraminifera, utilising high voltage transmission electron microscopy (HVTEM) of specimens thinned by ion bombardment[3,4]. We find certain ultrastructural characteristics to be common both to all Foraminifera studied and to all other comparison biological carbonate: for example, organic inclusions are found within and on the boundaries between the crystals of miliolid, fusulinid and rotaliid foraminiferal tests, bivalve shells, coral skeletons and human teeth. Other characteristics are typical of a particular host mineral, but independent of phyletic affinities: for example, the size, shape and abundance of inclusions are different in aragonite crystals from calcite crystals. Still other characteristics are diagnostic of certain groups: for example, crystal sizes and shapes are definitely different for the various suborders of Foraminifera. These ultrastructural characteristics should lead to a better understanding of the relationships between groups of Foraminifera, and to a better understanding of the biological calcification process in general. But more immediately, they provide powerful criteria for the evaluation of ultrastructural modification during and after fossilisation, especially for extinct forms such as the fusulinid Foraminifera.

Fusulinids possess one of the six major wall structure types known in calcareous Foraminifera[1,2]. Termed microgranular, it is characteristic of all species assigned to the extinct Palaeozoic suborder Fusulinina[1]. The microgranules are a few micrometres across, equidimensional and subangular[2]. They were thought to be either agglutinated particles picked up by the organism, or as most workers now believe, to be originally secreted[2]. As recrystallisation is common in fossils of this age, the nature of the microgranules has remained poorly understood.

These microgranules may be aligned with each other in varying degrees, thus forming fibrous or pseudofibrous layers[1]. The layering arrangements in various groups of fusulinids have been well described and are used as systematic criteria[1]. We are not concerned with these structures which are commonly referred to as test wall structure; we studied the internal structure of the microgranules themselves, and the relationship between them.

We consider here the ultrastructure of some well preserved specimens of *Triticites moorei* from the Wayland Shale Member of the Graham Formation (Pennsylvania) 10 miles north-east of Breckenridge, Texas (this is locality C-16 of Cushman and Waters[5]; the original description of *T. moorei* was by Dunbar and Condra[6] from the same formation north-west of Breckenridge). From examination of numerous specimens by optical and scanning electron microscopy, we selected four for detailed study. Examination by HVTEM indicates that the specimens retain their distinctive biological ultrastructure, including preservation of minute organic inclusions.

The degree of preservation of surface morphology is excellent. In some specimens we find evidence of surface damage, perhaps due to current action before incorporation into the sediment, but no evidence of solution effects has been observed.

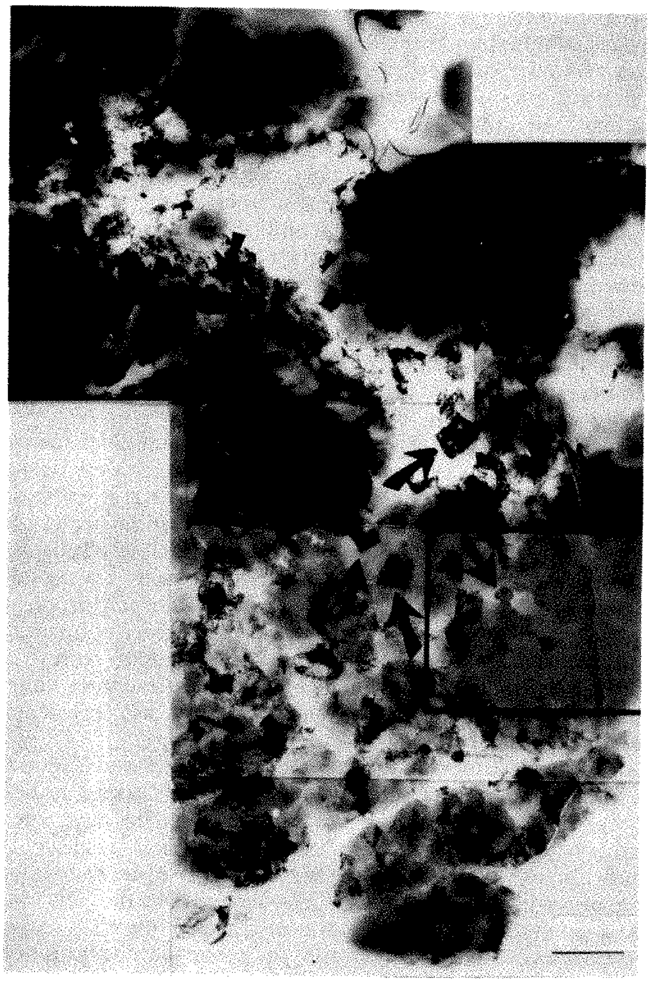

Fig. 1 HVTEM mosaic showing the general shape of test crystals and the contour of the surface. Irregular bright areas are very thin regions or holes in the specimen (~1 μm thick). Arrows point out crystals with characteristically faceted shapes. Tilting in the microscope to bring different crystals into good diffraction conditions shows that most crystals have these shapes. 1,000 kV. Rectangle shows the area of Fig. 2. Scale bar, 5 μm.

By HVTEM, the lack of surface alteration is shown by the smooth outline of the test wall against the coarse 'sparry' calcite which now fills the chambers (Fig. 1). The individual microgranules of the test are equidimensional, 1–5 μm diameter crystals bounded by faces with numerous re-entrant angles (Figs 2 and 3). Note that this microstructure is distinctly different from that produced by recrystallisation of calcite or other monomineralic substances (for example, photomicrographs and electronmicrographs of recrystallised calcite, quartz and olivine are indistinguishable from each other[7–9]). A recrystallised microstructure consists of equant crystals with dominantly planar faces such that the grain boundaries approximate a 'foam' structure produced by equilibration of grain boundary energies. Re-entrant angles are exceedingly rare, and the orientation of crystal faces is unrelated to the crystallography of individual crystals. In these fusulinids, however, the opposite is true; re-entrant angles are common (Figs 2 and 3) and large numbers of crystals have symmetrically related faces (Figs 1 and 2) and faces parallel to internal surfaces (Fig. 3). These features are reminiscent of the miliolid wall structure seen in HVTEM of *Alveolina quoii* d'Orbigny, although in the miliolids the crystals are greatly elongated in one direction (compare with Pl. 9, Fig. 4 of ref. 4). Within the fusulinid crystals and on the boundaries between them, voids are abundant (Fig. 3). These voids range downward in size from ~1,000 Å to <50 Å. Within individual crystals, voids tend to be approximately spherical or ellipsoidal,

but some of the larger ones are irregular. Grain boundary voids are commonly sharply angular and frequently a tetrahedral gap with perfectly planar faces left between four crystals which did not quite grow together can be seen (Fig. 3*c*). These voids probably contained organic matter originally, but are now empty. In addition to the voids, however, all crystals of the test contain myriads of very small inclusions with images ranging in size from ~100 Å down to the resolution of the microscope, ≈4 Å (Fig. 3*b*). The visibility and apparent size of these inclusions are critically dependent on the diffraction conditions because they produce strain contrast in the host calcite; hence their maximum size may be <100 Å. The inclusions are concentrated on low angle (subgrain) boundaries but are also abundant in regions of perfect crystal. Dislocations are rare in these crystals; some do and others do not have concentrations of inclusions along them.

In contrast to the crystals of the test, the infilling 'sparry' calcite crystals are very coarse-grained, and commonly only a few crystals fill an entire chamber. Voids are rare in these crystals and inclusions are totally absent. Dislocations are locally abundant (Fig. 2) and are occasionally organised into subgrain boundaries; in other areas the dislocation density is very low ($<10^6$ cm^{-2}). In many areas the infilling calcite displays a poorly defined lamellar structure with a wavelength of a few hundred ångströms (arrow, Fig. 2). This latter structure greatly resembles the incipient exsolution lamellae (spinodal decomposition?) common in pyroxenes from igneous rocks[10] and may represent a similar phenomenon.

Alteration of fossils by solution effects or recrystallisation is very common[11]. As a consequence we initially hoped to find some small regions of the samples which might have been preserved through the nearly 300 Myr since their fossilisation. Surprisingly, we find that virtually everything we see seems to be free of modification. We reach this conclusion by the following reasoning: (1) Even on the scale of the electron microscope, external form of the fossils is faithfully preserved; the transition to the infilling calcite is abrupt. (2) The crystal shapes are unlike any polycrystalline calcite ever described; in particular they are unlike extremely fine-grained natural and experimentally recrystallised material[9]. Moreover, except for lack of elongation, these crystals and the voids between them display many of the characteristics of living miliolids[4]; the shapes observed seem to be the result of mutual interference of faceted crystals growing in an isotropic medium—like crystals in an igneous rock. (3) The pattern of voids and minute inclusions in the crystals of the test is distinctly different from that of the infilling calcite, yet absolutely characteristic of the shells of Foraminifera and other organisms[3,4]. (4) The infilling calcite contains a lamellar structure which is not found in the tests, suggesting a different chemistry.

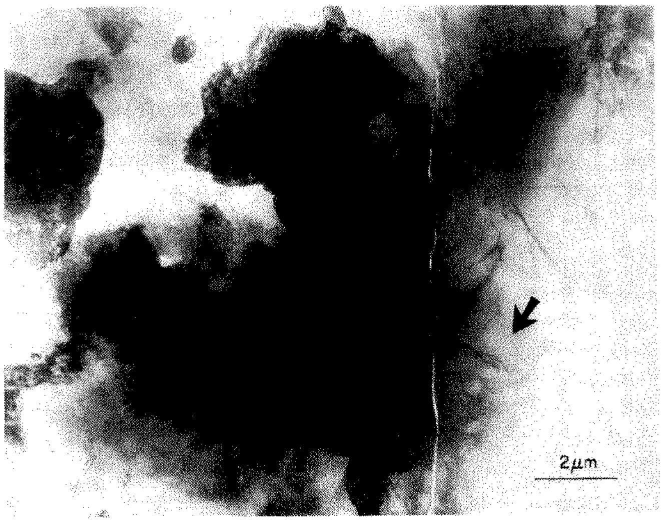

Fig. 2 Detail of portion of Fig. 1 with specimen tilted to a new orientation to show clearly the substructure of the infilling calcite. Note that the crystals of the test appear different than in Fig. 1. This is due to change in the diffraction conditions of individual crystals. Arrow points to lamellar feature in infilling calcite (see text). Scale bar, 2 µm.

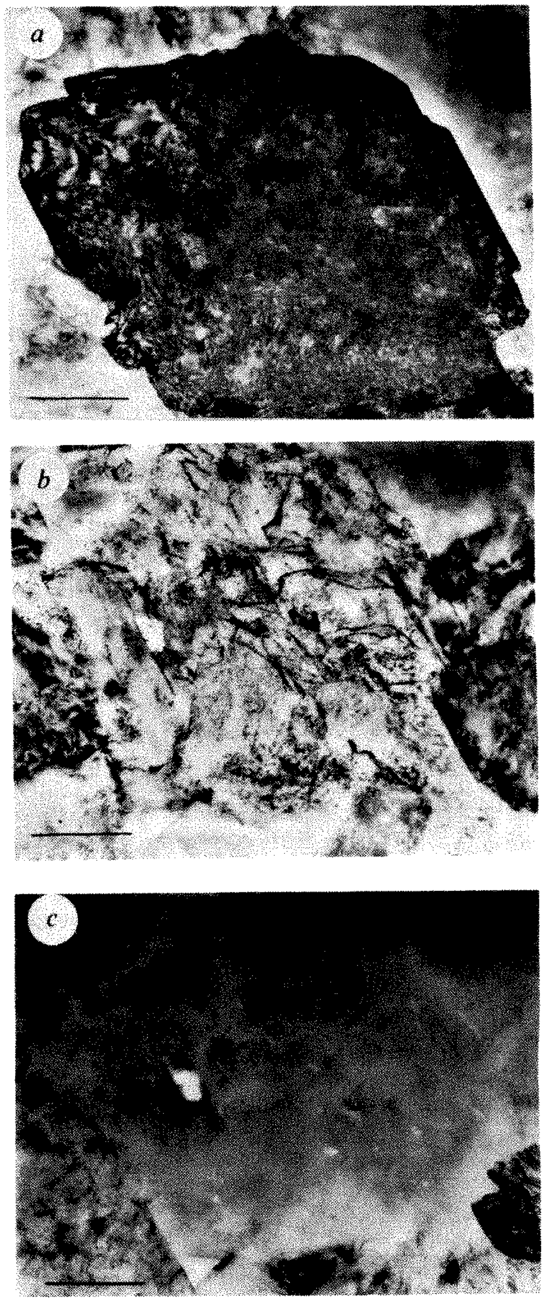

Fig. 3 Detail of typical crystal from interior of test wall. Note planar crystal faces with re-entrant angles. 1,000 kV. Scale bars, 1 µm. *a*, Crystal in strong diffraction contrast. Irregular mottling is caused by elastic distortion of crystal around minute inclusions. *b*, Same crystal, different tilt. Crystal now is in strong contrast only in distorted regions around inclusions. Note internal boundaries parallel to external faces. *c*, Same crystal, tilted to minimise contrast around inclusions. Numerous voids are now visible, including the large triangular one at the lower left where a corner of this crystal meets two others. Note that in detail this void is a triangular pyramid with planar sides.

Of course, a pseudomorphous replacement of the original crystals (calcite or another mineral) could be postulated such that the original, biogenic texture was preserved. This is unlikely because no evidence of such replacement has been found. Moreover, the distribution of inclusions makes such an *ad hoc* hypothesis doubtful because the behaviour of both fluid and solid inclusions during inorganic recrystallisation is well known: inclusions either interfere strongly with grain growth, resulting in a distinct and characteristic modification of the texture, or they are swept out of the interior of grains and concentrated at the boundaries. We do not know of any case where large numbers of very small inclusions remain undisturbed as a grain boundary migrates past them, nor would it be expected.

The similarities to miliolid ultrastructure and the similarity of both to interference structures such as in igneous rocks or metal castings suggest that the individual crystals grew independently in a fluid or fluid-like environment (in this case probably organic matter)[2]. Each crystal grew with its characteristic crystal faces until it came into contact with other crystals. At the point of contact the two crystals would interfere and one or both would lose its crystallographically controlled shape. The preservation of part or all of the crystal form on the majority of crystals indicates that, as in the miliolids, the calcification process did not go to completion; a significant volume remained occupied by organic matter. This is also likely to be the process of calcification of miliolids; it is possible that the different crystal shapes between the two groups are controlled by the chemistry of the organic medium, much as experimental crystal growth can be controlled by adsorption of specific impurities on certain crystal planes.

Although we argue that the basic microgranular test ultrastructure is original, two types of alteration could still be present: (1) Part of the original intercrystalline organic matter may have been replaced by inorganic calcite during diagenesis. We believe that any such replacement must have been minor because there is no general fine-grained matrix between original crystals, and the pattern of inclusions within the original crystals extends to the grain boundaries, making diagenetic overgrowths also unlikely. (2) The chemistry of the test calcite crystals could conceivably have been modified. Towe and Hemleben[11] have shown that fossil miliolids can retain the external form of their original crystals, yet have a much lower Mg content than the crystals of living miliolids. It remains to be demonstrated whether such cation exchange could leave unaltered the pattern of minute inclusions within crystals reported here.

The strong strain contrast around the intracrystalline inclusions indicates that they remain filled. The same effect is apparently seen here as that around the inclusions in living species of Foraminifera and other organisms, and in these latter cases the larger inclusions can be seen to contain organic matter[4]. Unfortunately, we have not found any inclusions in these fusulinids which are large enough to identify organic matter positively within them (the same is true for many modern foraminiferal tests; those that have very small crystal sizes also have very small inclusions). Nevertheless, the evidence suggests that the original contents of these inclusions are still there—locked away and protected inside their calcite 'bottles'—and possibly material could be concentrated from specimens and analysed.

This work was supported by NSF grant EAR 76-13687. We thank Helen Tappan for specimens of *T. moorei*.

Genetic heterozygosity in a natural population of *Mus musculus* assessed using two-dimensional electrophoresis

Robert R. Racine & Charles H. Langley

Laboratory of Animal Genetics, National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, North Carolina 27709

Since the introduction of gel electrophoresis to population genetics, estimates of genic heterozygosity at allozyme loci have been made for many organisms[1]. However, attempts to extend the range of proteins surveyed[2–4] have been hampered by concern that there may have been bias in the loci sampled: nearly all proteins for which population data are available are soluble in low-salt extracts and most are enzymes belonging to particular groups such as the nonspecific esterases and phosphatases, various dehydrogenases and the enzymes of the glycolytic pathways and the citric acid cycle. Until recently, there were no techniques for estimating protein variation which were without such bias. Two-dimensional gel electrophoresis[5], however, offered hope of overcoming this bias, and it has proved useful for the resolution of proteins in crude homogenates and for estimating genetic variation[6–9]. We have examined heterozygosity in a wild population of the house mouse (*Mus musculus*) by means of two-dimensional electrophoresis of whole kidney. As we report here, the observed level (2%) is substantially below the level detected by starch gel electrophoresis[10–12]. Our results corroborate similar differences observed in *Drosophila*[6] and man[7,9].

The O'Farrell[5] technique is a method for high-resolution, two-dimensional separation of proteins in polyacrylamide gels. It involves two independent criteria for separation. In the first dimension, denatured proteins are separated according to their molecular weight as assessed by SDS electrophoresis. However, certain questions must be answered before the method can be applied to surveys of genetic variability. Can products of distinct structural loci be distinguished? Can allelic substitutions at a single locus be distinguished? What is the bias of this method with respect to the protein type examined? From O'Farrell's[5] original estimates and from subsequent experiments[13], it is evident that gene products of different loci can routinely be distinguished, and that amino acid substitutions involving residues of different charge will be detected[14,15]. However, there seem to be other, perhaps conformational, differences[6,16] detectable by native electrophoresis (electrophoresis in non-denaturing conditions), or native isoelectric focusing (IEF) that are not detected with O'Farrell's technique. The inherent bias of this technique is towards loci with more abundant gene products, as the detection depends on nonspecific protein staining or labelling.

Figure 1 shows a typical two-dimensional protein pattern from a SDS-urea extract of a mouse kidney. About 100 spots can easily be scored. In our survey, we scored only spots in the

Table 1 Polymorphic loci detected in the Skokholm wild population of the house mouse (*Mus musculus*)

Allele designation	Frequency	Expected heterozygosity
a_1	0.64	0.46
a_2	0.36	
h_1	0.44	0.49
h_2	0.56	
i_1	0.80	0.32
i_2	0.20	

Expected heterozygosity is calculated as $1-(f_1^2+f_2^2)$, where f_1 and f_2 are the frequencies of the number 1 and 2 alleles, respectively.

0028–0836/80/090855—03$01.00

central region of the gel, as the *p*H gradient (indicated in Fig. 1) becomes nonlinear at the edges, resulting in loss of resolution in the IEF. We identified three spots showing variation consistent with a simple genetic interpretation[17] (Fig. 2). Protein *a* is isocitrate dehydrogenase (Id-1), which maps on chromosome 1 (ref. 17). The frequencies of the alleles controlling the variant Id-1 spots are shown in Table 1. We were not able to identify the biochemical role of the other two proteins[17]. Table 2 summarises our results and gives the calculated average per-locus heterozygosity together with information on the allozymic variation provided by Berry[10].

We have taken into consideration the fact that a single allele of locus *a* (identified as Id-1) displays two spots on a two-dimensional gel by doubling the expected heterozygosity of locus *a* (Table 1) for calculating our average per-locus heterozygosity. The display of two spots by one allele is probably a result of the long storage time of the kidney tissues (>2 yr, R. J. Berry, personal communication), as we did not observe this on fresh samples[17]. In connection with another study[17], we have made a similar observation with 2-yr-old purified Id-1 enzyme[18]. This enzyme preparation displayed several spots across the slab gel at the appropriate molecular weight (R.R.R., C.H.L. and C.-Y. Lee, unpublished results). Similar multiple spots per allele have been reported[9,14]. The 17 loci known to show genetic variation in these studies exhibit 20 spots on two-dimensional gels[6,9,14,17]. We can therefore estimate that the number of loci surveyed is 85% (17/20) of the number of spots scored. The number of consistently scorable spots (85) probably then represent about 72 individual structural loci.

The threefold reduction in heterozygosity (Table 2) obtained by two-dimensional rather than native electrophoresis on the same mice is striking. This observation is in accordance with studies on *Drosophila*[6] and man[7,9]. The difference probably arises from the ability of two-dimensional gel electrophoresis to

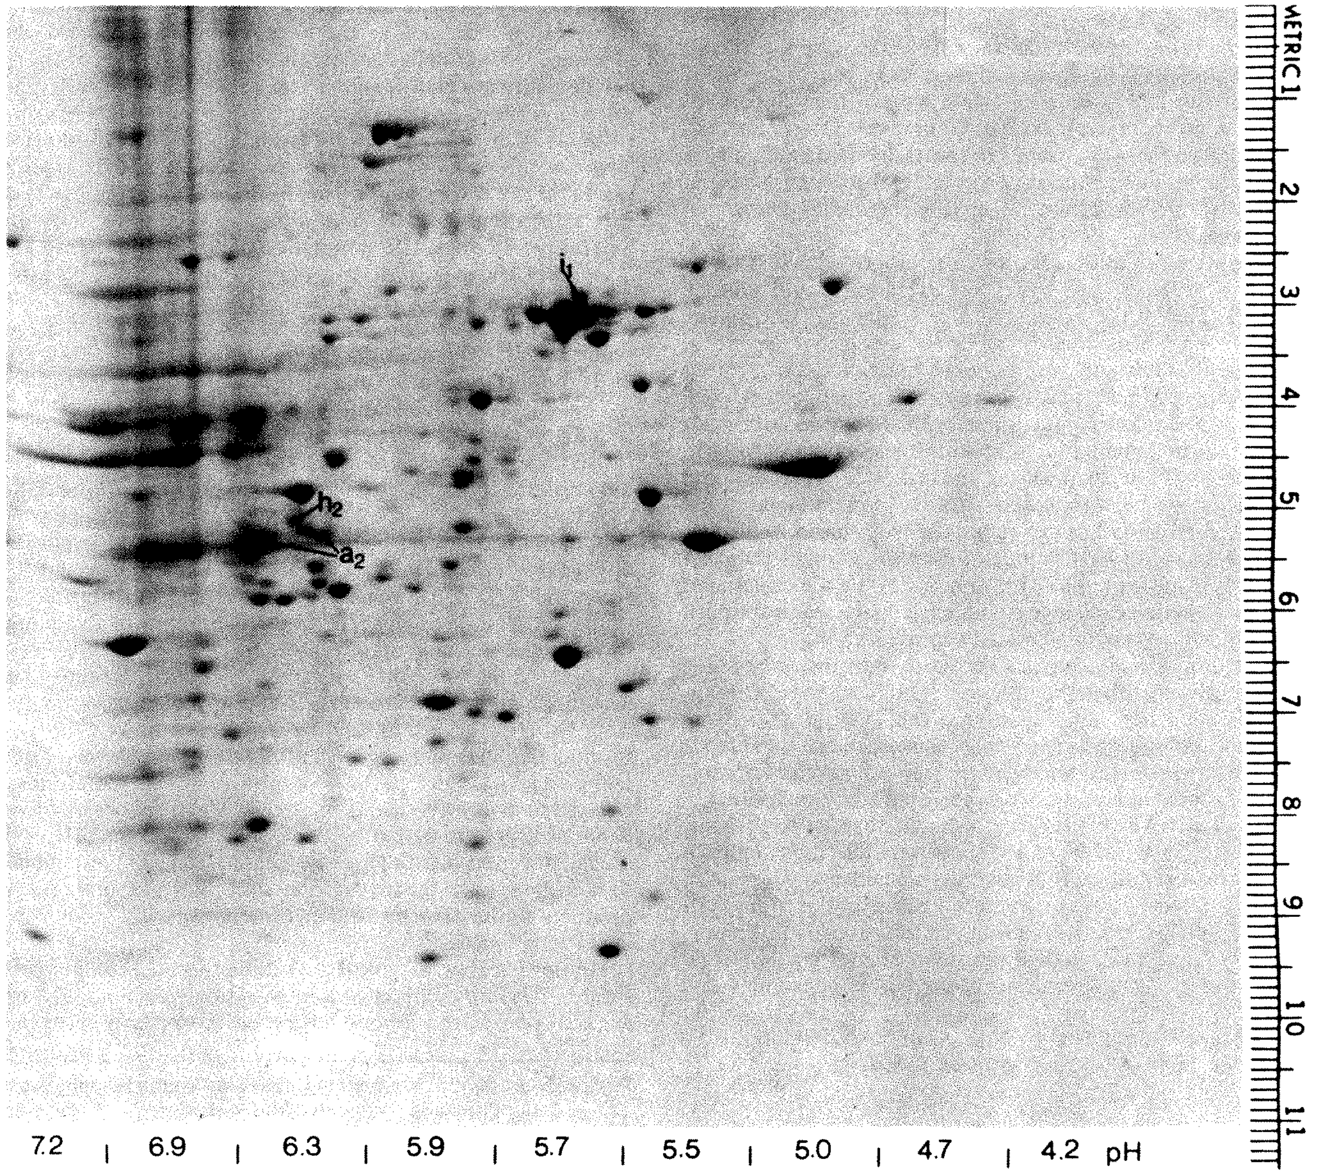

Fig. 1 Two-dimensional gel of a crude kidney homogenate of a wild mouse from Skokholm. *a*, *h* and *i* refer to the three polymorphic spots found. Samples were prepared according to the method described by Wilson *et al.*[20]. Samples (50 μl) were loaded onto the isoelectric focusing (IEF) gels following the procedure of O'Farrell[5]. IEF was carried out in 11.5-cm long Pyrex tubes with an internal diameter of 2 mm, using the same mixture of *p*H 3.5–10 and *p*H 5–8 carrier ampholytes as O'Farrell. SDS slab gel electrophoresis in 10% acrylamide was also carried out as described by O'Farrell. All slab gels were fixed in a mixture of 45% methanol and 10% acetic acid overnight and stained in the same solution containing 0.02% Coomassie brilliant blue R-250. Gels were destained in a mixture of 25% methanol and 7% acetic acid. They were photographed on Polaroid type 55 positive/negative film with a red filter. Throughout, 1% dithiothreitol (Eastman) was used instead of 5% mercaptoethanol. All other reagents were obtained from the same sources[5]. Molecular weights in the slab gels were determined by running in parallel RNase (13,000), chymotrypsinogen (25,000), aldolase (subunit 40,000) and ovalbumin (45,000) (all Pharmacia).

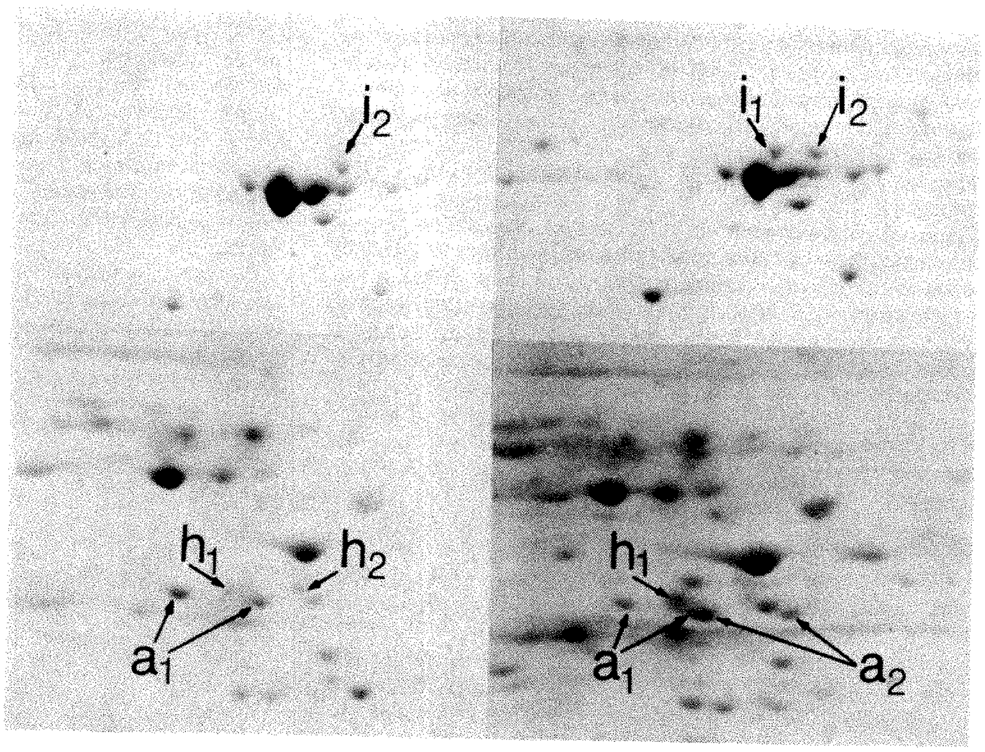

Fig. 2 Two-dimensional gel patterns of the variant regions.

survey previously inaccessible classes of proteins. The two techniques cannot be directly compared, as IEF is not capable of resolving several enzyme variants in *Drosophila* which can be distinguished with standard, one-dimensional methods[16]. Leigh Brown and Langley[6] have compared 10 species of *Drosophila* using α-glycerophosphate dehydrogenase identified on a two-dimensional gel. Several species showed slight differences in mobility in standard starch gel conditions, but on two-dimensional gels only major charge differences (such as the usual slow/fast polymorphism) were detected. Carbamylation experiments[14,15,19], however, show that two-dimensional electrophoresis can resolve all substitutions in the primary structure of a protein which result in a charge difference. The extra variation observed in native, one-dimensional gels is therefore either conformational or post-translational in nature. As the two-dimensional gel technique detects only charge-change substitutions, estimates of total heterozygosity are impossible.

Table 2 Comparison of average per-locus heterozygosity levels between two-dimensional (2-D) and starch gel electrophoresis evaluated in the same wild mice from Skokholm

	2-D gels	Starch gels
No. of loci scored	72 (85)	26
No. of loci polymorphic	3	5
Expected heterozygosity	0.020*	0.172

Number in parentheses indicates the actual number of proteins scored. For further explanations see text. Starch gel data are from an extensive study done by Berry[10].

* Calculated $0.020 = (2 \times 0.46 + 0.49 + 0.32)/85$.

However, if the conditions used in most standard, one-dimensional surveys of allozyme variation are also such as to detect only full charge differences, as is likely, the drop in heterozygosity evaluated by two-dimensional electrophoresis compared with standard electrophoresis, is striking. It might suggest that the most abundant proteins in mouse kidneys represent a group of proteins which are different from and less variable than those which are detected in standard electrophoresis. However, if the proteins identified with the two-dimensional technique are representative of most mouse proteins, the average level of genic heterozygosity is much lower than that previously estimated.

We thank Dr R. J. Berry for the mouse kidneys.

Identification of specific leech neurones immunoreactive to enkephalin

Birgit Zipser

Cold Spring Harbor Laboratory, PO Box 100, Cold Spring Harbor,
New York 11724

The small endogenous peptides, Met- and Leu-enkephalin, bind to the same specific receptors as opiate analgesics. They, and the larger endorphin peptides, have been widely found in mammals, where they seem to have a significant role in neuronal pathways mediating pain and emotional behaviour. Only recently has enkephalin-like activity been identified in an invertebrate, the earthworm[1], although there is some preliminary evidence for opiate receptors in a marine mollusc[2]. Here I report the detection, by an immunocytochemical technique, of an enkephalin-like moiety which is localised in one of the 400 cells of each posterior midbody ganglion of the leech. The presence of enkephalin-like activity in an identifiable easily accessible neurone of a well characterised nervous system such as that of the leech[3–5] could greatly facilitate elucidation of its mechanism of action.

0028–0836/80/090857—02$01.00

Neurones in the refrigerator-stored leech react optimally to Leu-enkephalin antisera (Immuno Nuclear Corporation) at dilutions of 1/5,000 and 1/10,000. The same concentrations of this batch of serum also gave optimal immunocytochemical staining of monkey spinal cord sections (Ellyn Glazer, personal communication), indicating that the immunoreactivity to enkephalin in leech ganglia is of similar strength to that in the mammalian material.

Figure 1*a* shows a series of three successive midbody ganglia from a single leech stained for Leu-enkephalin. Only one cell body at about the same position in each ganglion is immunoreactive. This 30-μm cell body appears on the ventral surface in the posterior half of the ganglion. A stained process leading from this cell body can occasionally be seen in the microscope but is hardly visible in the photographs.

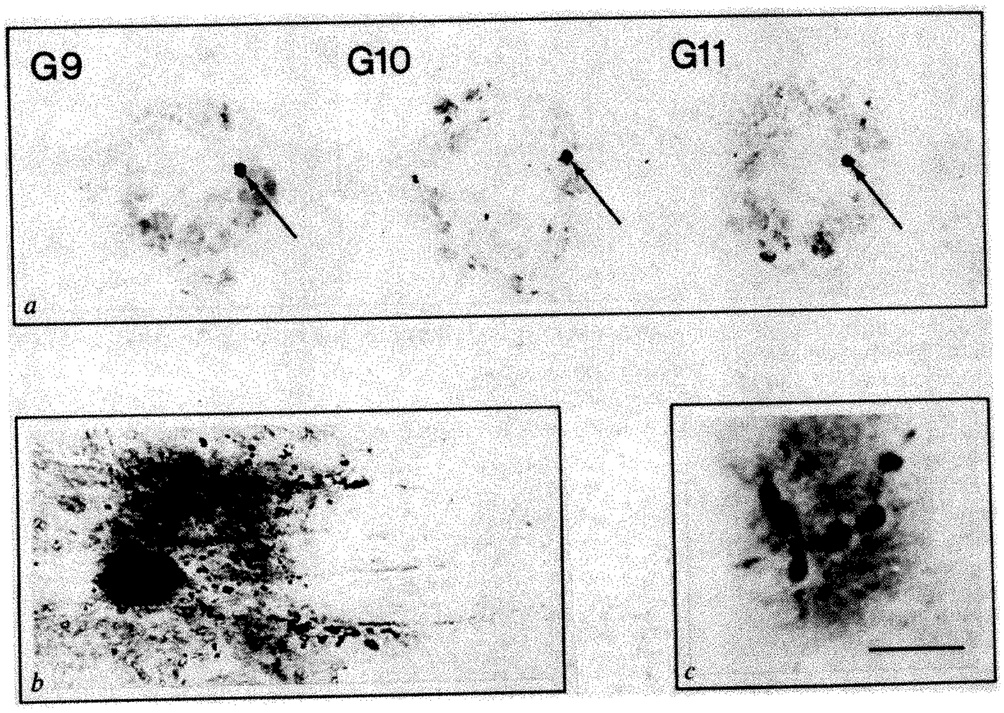

Fig. 1 Enkephalin-immunoreactive cell bodies and neuritic processes in leech ganglia. *a*, A specific cell body in successive ganglia of a *Haemopis marmorata* leech stained by reaction with PAP-coupled Leu-enkephalin antisera. *b*, *c*, The central neuropile showing immunoreactive processes and varicosities. The immunocytochemistry was done on whole ganglia whose ventral capsules were cut to expose the ventrally located unipolar cell bodies. To facilitate diffusion of antibodies across membranes, the 4% paraformaldehyde-fixed ganglia were put through a successive alcohol series into xylene and brought back into buffer before a 2-day incubation with serum containing 0.2% saponin. Calibration: *a*, *b* and *c* are 150, 35 and 13 μm, respectively.

Figure 1*b* and *c* show photomicrographs of the central neuropile of a midbody ganglion at two magnifications. In Fig. 1*b*, a pattern of immunoreactive varicosites is visible. These darkly staining entities at the level of the neuropile strongly resemble nerve terminals of other neurones in the leech[6]. They seem to have a wide size range, with the largest reaching about 4 μm. The individual varicosities are visible at the high magnification of Fig. 1*c*. These varicosities are present in all ganglia, even those in the anterior cord, where cell bodies are generally not stained.

The presence of bound antibody was demonstrated using the peroxidase–antiperoxidase (PAP) procedure developed by Sternberger[7]. Following the incubation with rabbit anti-Leu-enkephalin (Immuno Nuclear Corporation), the ganglia were washed and incubated with goat anti-rabbit IgG (1/20; Cappel) for 30 min, then with the PAP complex (1/250; Cappel) for another 30 min, and finally stained by reaction of peroxidase with 3',3-diaminobenzidine.

Non-immune and Leu-enkephalin-blocked controls were run to confirm that the stained structures were reacting specifically to antibodies against enkephalin. Half ganglionic chains of three different leeches were incubated with non-immune serum of the same dilutions as the enkephalin antisera and neither the 30-μm cell body nor the varicosities were stained, whereas material from the same leeches run in parallel with enkephalin antisera was stained. Leu-enkephalin antiserum was blocked by incubation with Leu^5-enkephalin (Boehringer) at concentrations of 500, 100 and 20 μg ml^{-1}. The 30-μm cell body was not stained over this full 25-fold range. The reaction of the varicosities was concentration dependent; they were not stained when the serum was blocked with Leu-enkephalin at 500 and 100 μg ml^{-1}, but reappeared faintly at 20 μg ml^{-1}.

In ganglia 5, 6 and 7, instead of a single neurone, several cell bodies can show immunoreactive product. Ganglia 5 and 6 innervate the sex organs and are about 80% larger than the typical midbody ganglion; ganglion 7 has no known specific function.

The most significant aspect of this work is that antisera to Leu-enkephalin reacts positively with one specific cell body that maintains the same size and location in successive ganglia within the posterior two-thirds of the midbody ganglionic chain. By analogy with other leech neurones, it is likely that these cell bodies are homologues which can be identified and studied electrophysiologically. It will be interesting to see if the pattern of enkephalin-like distribution observed here with leeches kept in the cold changes when animals in different behavioural states are studied.

The varicosities that show up so prominently with Leu-enkephalin antisera are presumably enlarged synaptic endings with a high peptide content, as they reappeared earlier than the cell bodies when the enkephalin concentration blocking the antiserum was lowered to 20 μg ml^{-1}. Near the head there are ganglia with clearly stained varicosities but no stained cell body, indicating either that not all enkephalin-containing neurones have stained cell bodies, or that some enkephalin-containing terminals originate from cells in other ganglia.

I thank Ellyn J. Glazer and Allan I. Basbaum for helpful discussions. This work was supported by NSF research grant BNS 78-24672.

Reversible events in the transduction process of photoreceptors

K. Hamdorf* & K. Kirschfeld

Max-Planck-Institut für biologische Kybernetik, Spemannstrasse 38,
7400 Tübingen, FRG

In photoreceptors, a latency of many milliseconds elapses between the absorption of a light quantum and the occurrence of the late receptor potential, even for strong light stimuli. Surprisingly, this is much longer than the time necessary for conductance changes such as occur in membranes of neurones or muscles, mediated by chemical transmitters. There are several possible explanations for the long photoreceptor latency. (1) It may be due to properties of the visual pigment molecules. For instance, the temporal coincidence of the occurrence of metarhodospin II with the receptor signal indicates that the meta I-meta II transition might be the trigger for the electrical response in vertebrate photoreception[1]. (2) It may be explained by properties of transport processes. Such a time consuming process could be the diffusion of an internal 'transmitter substance', which diffuses to a 'pore' in the receptor membrane. (3) A third possibility is the time needed to produce and accumulate chemical substances. The light-induced change of the visual pigment molecule might trigger a chemical reaction chain, in which the product of an earlier step triggers the next one. The experiments described here show that a considerable part of the long latency in photoreception is due to processes that are localised at the level of the visual pigment molecule.

Photoreceptors of invertebrates have a stable metarhodopsin (M), which is reconverted into rhodopsin (P) by absorption of light[2,3]. This 'bi-stability' offers the possibility of discriminating between the different hypotheses. In the photoreceptors called R_{1-6} of the fly compound eye the transition of rhodopsin (P) into metarhodopsin (M) is fast (time constant $\approx 100\ \mu s$ at room temperature, 500 μs at 10 °C)[4]. This excludes the possibility that the kinetics of the photometrically determined pigment transition is the time-limiting process. Hypothesis (1) can thus be valid only if properties of the photopigment molecule other than those detectable photometrically are involved. The bi-stability of the visual pigment system of the fly photoreceptors allows one to reconvert $M \rightarrow P$ within the latency of the response. If hypotheses (2) or (3) were correct, an irreversible process should have been initiated within a fraction of a millisecond, and the reconversion of $M \rightarrow P$ should not affect the response. These hypotheses therefore can be rejected if it can be demonstrated that the reconversion reduces the response.

As will be seen below, a successful experiment can be performed only in receptors in which the rhodopsin content has been reduced to low concentration.

Figures 1 and 2 show the amplitude of the receptor response to light flashes as a function of intensity. With strong stimuli the response amplitude becomes saturated.

In the visual pigment system of receptors R_{1-6} of the blowfly, blue light shifts a maximal fraction of P into M, red light a maximal fraction of M into P[5,6]. With short double flashes (blue followed by red), P can be first converted to M and then back again within the latency of the response. The effect of such double flashes on the prolonged depolarising after-potential and the 'pupil response' in *Calliphora* has been described by Muijser and Stavenga[7].

Figure 1*c* shows responses to a blue flash and to the sequence blue–red. It is obvious that, compared with the single blue flash, the second red flash reduces the response amplitude. This result seems to be paradoxical because more absorbed light quanta lead to a smaller response. This paradoxical result is obtained only with the sequence blue–red, whereas the sequence red–blue leads to the same response amplitude as a single blue flash. Blue–blue double flashes always result in an increase of the response amplitude as long as the response has not been saturated by the first flash, and if the second flash is not given too late.

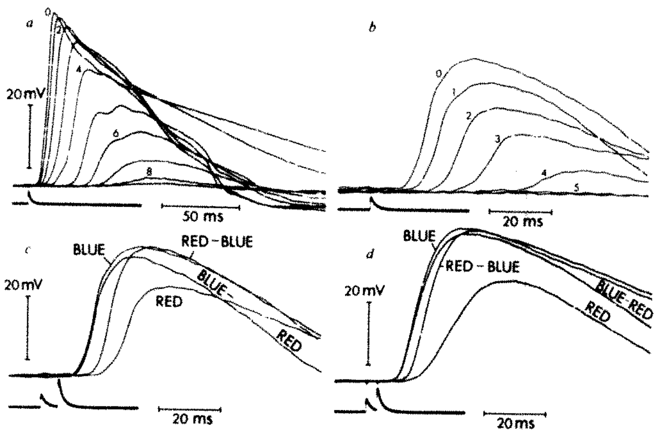

Fig. 1 Intracellularly recorded responses of photoreceptors (type R_{1-6}) of *Calliphora* female, chalky, to light flashes. Monitor, lower trace; temperature, 10 °C. *a*, Fly with high rhodopsin content in the receptors. Relative flash intensities were changed from 10^0 to 10^{-9} (numbers indicated on the traces). *b*, Fly with rhodopsin content reduced to 1/1,000 of normal. *c*, Same cell as that used in *b*. Stimulus, blue and red single flashes; blue–red and red–blue double flashes with 5 ms delay, all of maximal intensity. Note that the longer latency of the sequence red–blue is due to the fact that the blue flash occurs as the second one. *d*, Same stimulus programme as used in *c*, delay between double flashes 3 ms; records from another fly.

The amplitude to the sequence blue–red corresponds to an amplitude to a single blue flash reduced to some 25% of maximal intensity. This can be seen from the intensity amplitude function (Fig. 2). The response is not completely abolished for two reasons. First, for technical reasons, the second red flash was not bright enough to reach equilibrium completely. Hence, from the M created by the first flash, only two-thirds are shifted back into rhodopsin. Second, the red flash by itself shifts a small amount of P into M. From the amplitude of the red response this amount can be estimated to be 1–2% (see arrow in Fig. 2).

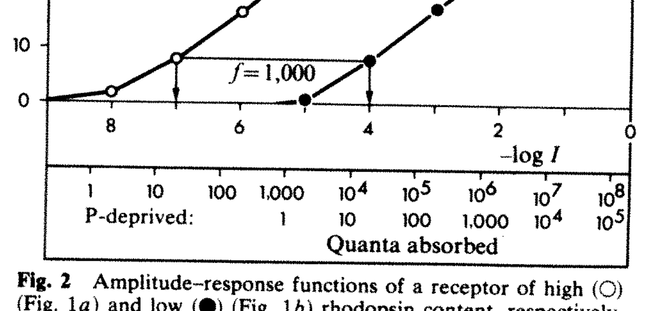

Fig. 2 Amplitude–response functions of a receptor of high (○) (Fig. 1*a*) and low (●) (Fig. 1*b*) rhodopsin content, respectively. Abscissae, –log relative intensity; quanta absorbed. Ordinate, amplitude of receptor potential in mV. Arrows indicate amplitudes of responses from Fig. 1*c* to blue, blue–red and red flashes. *f* values indicate sensitivity factors.

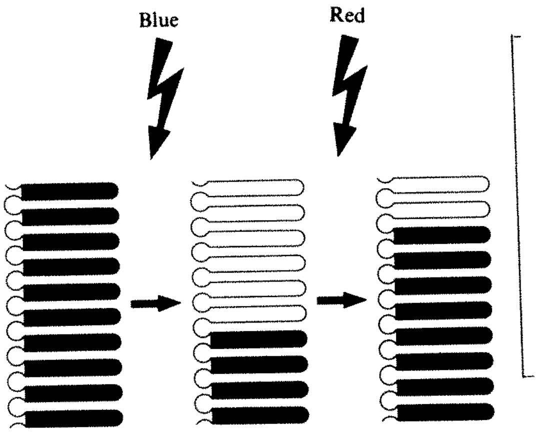

Fig. 3 Microvilli (shown schematically) with visual pigment in either rhodopsin (P) (black) or metarhodopsin (M) conformation. The first blue flash shifts some 60% of P into M; after the second red flash only 20% of the pigment is left as M.

If we want to stop the conductance change induced by the P→M conversion, we must hit the same molecules with the second red flash. The probability of doing so is high only at very high flash intensities which already saturate the cell. Hence, a possible reduction of the response to the blue–red double flash cannot be detected at normal visual pigment content of the receptors. To remain below the saturation of the response we must reduce the pigment content to such a degree that less than 10^5 pigment molecules can be hit; this means that the pigment concentration must be <1 ‰ of normal[8]. (The reduction in P content to <1‰ of normal was achieved by raising flies in special conditions developed by Schwemer[9].) In this condition, the sensitivity of the receptors is markedly reduced (Fig. 2), but, as has been shown, the double-flash experiment can be successfully performed (Fig. 1*c*, *d*). Quantitatively we obtain the following situation. The first blue flash shifts 60% P into M. The second red flash shifts back 65% of those M molecules, so that 20% remain (Fig. 3). These values have been derived from photometrical measurements in the experimental set-up used for the electrophysiological experiments[10].

If the pigment content is sufficiently reduced, the amplitude to the blue–red double flash is always smaller than that to the blue flash alone. However, the amplitude reduction was often not as prominent as that shown in Fig. 1*c*, and corresponded to a loss in sensitivity by a factor of only 2 to 3.

Following the conversion of P to M ($\tau \approx 500$ μs, 10 °C), there remains a period of 3–5 ms during which reconversion of M to P more or less completely abolishes the effect of the initial P→M conversion (Fig. 1*c*, *d*). During this period no irreversible transmitter release or chain reaction could have been initiated. It is true that there remain a further 3–4 ms before the onset of the response during which such processes may become important. What has been clearly shown is the existence of a distinct, time-limiting process in transduction localised at the level of the pigment molecule and lasting a few milliseconds.

Furthermore, we are able to decide whether the response of the receptor is due to the total number of P–M conversion or to the number of M molecules remaining after the stimulus. Because, in both flash sequences (red–blue; blue–red), the number of P–M conversions is the same whereas the number of M molecules remaining is different, it must be the M molecules remaining after the flashes which trigger the conductance change.

As we are able to stop the sequence of events within 3–5 ms, the action of the freshly created M must last longer than 3–5 ms in order to trigger the response. After having excited the membrane, the M molecules remain as thermostable M without any further excitatory effect. Therefore, it is the newly created M which excites the membrane. This M has been called 'energy rich' in the photoreceptor membrane model developed from other experimental evidence[11].

Photoreceptor signals at visual threshold

C. A. Dvorak*, A. M. Granda† & J. H. Maxwell

Institute for Neuroscience and Behavior, University of Delaware, Newark, Delaware 19711

Electrical responses of cone photoreceptors in the retina of the freshwater turtle have been characterised for flashes and steps of light in darkness and in the presence of background light[1–4]. These intracellular measurements have been combined with the behavioural increment threshold curve to yield an estimate of 5–10 μV for the signal developed in a cone when the turtle can just detect an increment flash[5]. The signal developed when the cones under the stimulus image are dark-adapted is of interest, for its measurement would help to explain how known physiological processes subserve visual detection for a variety of photic conditions. The effective quantal absorption of dark-adapted, red-sensitive cones of *Pseudemys scripta elegans* for a stimulus that the turtle can just detect is reported here. By combining this result with previous electrical measurements on red-sensitive cones of this species, an estimate of 35–70 μV is obtained for the signal developed in a dark-adapted cone at behavioural threshold. This larger signal required for detection of a flash in darkness is of particular interest in view of the recent observation[6] that the intrinsic noise of turtle cones in darkness is larger than that of illuminated cones.

Details of the experimental apparatus and the behavioural paradigm have been presented elsewhere[1,7]. Basically, the animal was placed in an experimental chamber with its head positioned so that the stimulus image fell on the central linear streak of the retina. The turtle was trained to avoid an electric shock by pulling in its head whenever it detected a flash of light. An 'up-down' tracking procedure was used to determine the threshold with mean 95% confidence intervals of about 0.1 log units. The animal was dark-adapted for 45 min before presentation of a 2.35° diameter stimulus for 125 ms. As these values represent the approximate critical area and the exact critical duration for white (tungsten) light (see Figs 31 and 32 in ref. 1), essentially complete spatial and temporal summation occurred. The radiant emittance M_e of the source was determined as a function of wavelength using a calibrated thermopile, and for the attenuated stimulus was 2.1×10^{-8} J cm^{-2} s^{-1}. From Lambert's law the radiance L_e of the stimulus was 6.5×10^{-9} J cm^{-2} sr^{-1} s^{-1}. The retinal irradiance E_e can be determined[8] from the relation $E_e = \pi L_e$ (n.a.)^2 for a numerical aperture (n.a.) that is equal to $nd/2p$ for refractive index n, entrance pupil diameter d and posterior focal length p. We used values of $n = 1.34$ and $p = 6.40$ mm from the schematic eye of *Pseudemys*, which has an actual pupil diameter of 1.74 mm (data of D. P. M.

Northmore in ref. 1). The entrance pupil is located 0.21 mm anterior to the actual pupil, and was determined to be 1.95 mm in diameter using the corneal magnification factor, which was calculated to be 1.12. This agrees fairly well with the approximate 10% reduction of apparent pupil size when the animal is placed in water, thereby cancelling the refractive power of the cornea. The resultant numerical aperture is 0.203, which, when substituted into the relation for the attenuated retinal irradiance, yields $8.6 \times 10^{-18}\ \mathrm{J}\ \mu\mathrm{m}^{-2}\ \mathrm{s}^{-1}$. When the neutral density of the optical media (0.04) (ref. 9) is taken into account, this figure is reduced to $7.9 \times 10^{-18}\ \mathrm{J}\ \mu\mathrm{m}^{-2}\ \mathrm{s}^{-1}$. The fraction of this just-detectable light at the level of the retina that is effective in terms of the red-sensitive cones was determined by numerically integrating the product of the mean spectral sensitivity of the cones and the spectral distribution of the light, then dividing by the integrated spectral energy of the light. The resulting value is 0.52. This reduces the retinal irradiance to $4.1 \times 10^{-18}\ \mathrm{J}\ \mu\mathrm{m}^{-2}\ \mathrm{s}^{-1}$, which represents the total energy in the stimulus to which red-sensitive cones are sensitive irrespective of wavelength. The optimal wavelength for both the cone sensitivity[2] and the light spectrum is 633 nm, and by weighting the energy at this wavelength a conversion to quanta can be made with a result of 1.6 quanta $\mu\mathrm{m}^{-2}$ per flash. The mean cross-sectional area of a 3.0-μm diameter oil droplet in a paracentral, red-sensitive cone of *Pseudemys*[10] is 7.1 $\mu\mathrm{m}^2$, yielding an average of 11.4 quanta per cone per flash based on the area of the oil droplet. This value is an estimate of the minimum quantal catch by the cone, as oil droplet area is on the average only half the area of the inner segment, according to measurements made prior to the droplet in peripheral cones[11]. Thus, if twice as much light were collected by the cone in view of this possible twofold difference, this value could be as high as 22.8 quanta per cone per flash. Approximately 12% of these 11.4–22.8 mean incident quanta are effectively collected, absorbed and transduced by the outer segment of a red-sensitive cone[11], so on the average 1.4–2.8 quanta are effectively used by each red-sensitive cone at the behavioural threshold. Since each effective photo-isomerisation in a peripheral red-sensitive turtle cone yields a hyperpolarisation of the membrane potential of about 25 μV (ref. 2), an average signal of between 35 and 70 μV is developed in each red-sensitive cone in response to a flash of light that the dark-adapted animal can just detect. An assumption made in arriving at this range is that paracentral, red-sensitive cones also develop approximately 25 μV per effective photo-isomerisation when a large number of adjacent cones are illuminated, as was the case in the determination of the response of peripheral cones.

For the data used in this analysis the results provide an estimate of what is probably a minimum range of effectively utilised quanta: the most sensitive electrophysiological and behavioural data available have been incorporated in our calculations. The use of any other data, such as larger red-sensitive cone diameters for measurements[10,11] taken from the peripheral retina of *Pseudemys*, would yield a larger estimate. To assure that no substantial error was introduced due to the use of white (tungsten) light, we also determined thresholds for red light by inserting a colour filter (Kodak no. 26) in the light path. Because of the decrease in total light available to the red-sensitive cones, the neutral density had to be decreased by 0.15 units in order to obtain an equivalent threshold. Of the red light thus presented we calculated that a difference of about 0.14 log units existed between the two stimuli in terms of their effectiveness in stimulating red-sensitive cones, in comparison to the 0.15 units found experimentally. Similar thresholds for the two stimuli are actually expected in view of the long-wavelength spectral bias of both the animal's sensitivity and the energy of either stimulus. Within experimental error (0.01 density unit), then, we have a determination of threshold using red and white lights that strongly suggests that the animal is using its red-sensitive cones to detect the spectral energy of both stimuli.

The estimate of 35–70 μV for the signal range of the dark-adapted, red-sensitive cones at threshold is several times the 5–10 μV estimate for red-sensitive cones mediating an increment threshold detection. Measurements of intrinsic membrane noise of red-sensitive cones of *Pseudemys* are up to four times larger in darkness than in light, depending on the extent of interreceptor coupling[12]. Thus the respective amplitudes of signals and noise underlying detection in darkness and in light have the appropriate relationship to suggest that the observed visual thresholds could be the result of a form of signal-to-noise discrimination of neural events that originate in the photoreceptors.

Our results indicate that each red-sensitive cone under the 2.35° stimulus spot effectively uses at least one photon, and possibly two. Under the conditions for which thresholds were obtained it would seem to matter very little whether or not the photoreceptors were electrically coupled in terms of their signals, for they would develop about the same photovoltage in either case, since a large number of adjacent cones are on the average absorbing the same number of photons. However, since coupling reduces noise in a given cone[12], the net effect of coupling would be to improve the signal-to-noise ratio during the detection of light under any condition for which a large number of coupled cones are stimulated.

Endocrine differentiation of the fetal rabbit ovary in culture

Fredrick W. George & Jean D. Wilson

Department of Internal Medicine and Eugene McDermott Center for Growth and Development, University of Texas Southwestern Medical School, 5323 Harry Hines Boulevard, Dallas, Texas 75235

Although virilisation of the male fetus is accomplished in large part by the secretion of testosterone from the testis during embryogenesis[1], little is known about the function, if any, of the fetal ovary in female embryonic development. On the basis of studies in rabbits, in which castrate fetuses developed as phenotypic females, Jost concluded that the ovary does not have an active role in sexual differentiation[2]. However, we have demonstrated that the onset of oestrogen formation in the fetal ovaries of rabbit and man occurs at approximately the same time that the fetal testis develops the capacity to form androgens[3,4], and Mauleon *et al.*[5] have demonstrated that the fetal sheep ovary secretes 17β-oestradiol before the onset of testosterone synthesis by the testis. These findings suggest that ovarian function is important during embryonic development. In the fetal rabbit, the onset of testosterone synthesis in the testis coincides with the appearance of 3β-hydroxysteroid-$\Delta^{4,5}$-isomerase activity[3,6,7]. The mechanism regulating the time of appearance and the amount of this activity remains unclear, although the enzyme develops in fetal gonads cultured in chemically defined medium[7], suggesting that the regulation of testosterone synthesis is intrinsic to the fetal testis. To gain insight into the factors responsible for the onset of endocrine function of the ovary we have compared the enzymatic development of embryonic rabbit ovaries and testes in organ culture. The results indicate that the enzymatic differentiation of fetal ovaries is also independent of hormonal induction and occurs in culture at the same time as endocrine differentiation of the fetal ovary *in vivo*.

0028-0836/80/090861—03$01.00

On day 16 of gestation (the day of observed copulation was designated day 0), New Zealand white rabbits were killed, the embryos were removed aseptically, and the gonads with adjacent mesonephros were dissected from the embryos. Pairs of gonads from individual embryos were cultured at 37 °C in Serumless Medium (Gibco) in a humidified atmosphere of 5% CO_2 in air in separate wells (1.6 cm diameter) of a Linbro plate (Flow Laboratories). Media were changed at 48 h, and fetal gonads and media were collected at the times indicated in the figure legends. The genetic sex of each embryo was determined by staining the amniotic membrane with thionin to show the presence or absence of sex chromatin by the method of Klinger and Ludwig[8]. All gonads in which corresponding amniotic membranes were sex chromatin positive were designated ovaries.

To assess the enzymatic differentiation of fetal testes and ovaries we measured the conversion of 1,2-^{3}H-dehydroepiandrosterone (54.7 Ci mmol^{-1}) to androstenedione, testosterone and 17β-oestradiol in a total volume of 0.2 ml Serumless Medium. Depending on the developmental stage, two to eight fetal ovaries or one to eight fetal testes (representing 0.05–0.1 mg protein) were used in each incubation. After incubation, appropriate ^{14}C-labelled steroids were added in trace amounts to assess recovery, and the samples were extracted and chromatographed as before[4]. Protein was determined by a modification[7] of the method of Lowry *et al.*[9]. Each of the steroids isolated by column chromatography was purified through several thin-layer chromatographic steps, and the authenticity of the isolated products was confirmed by recrystallisation. In addition we measured by radioimmunoassay[10] the 17β-oestradiol secreted into the media from ovarian and testicular cultures.

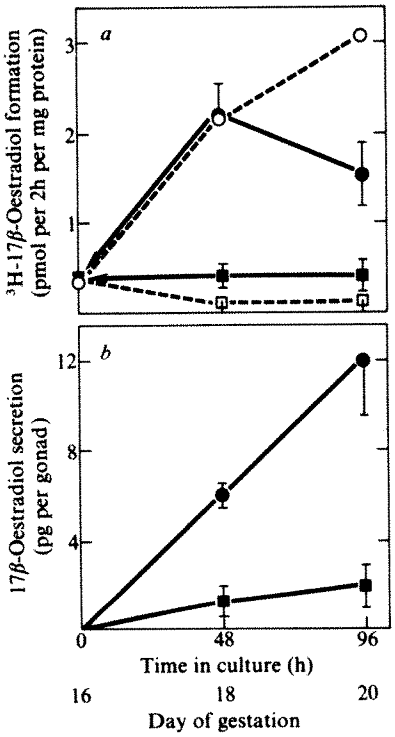

Fig. 1 Developmental pattern of 17β-oestradiol formation and secretion by cultured and *in vivo* control gonads. *a*, ^{3}H-17β-oestradiol synthesis. Cultured fetal gonads were collected 48 and 96 h after the initiation of cultures, dissected free of mesonephric tissue, and incubated with 5 μM 1,2-^{3}H-dehydroepiandrosterone as described in the text. The ^{3}H-17β-oestradiol formed during incubation was purified as before[4]. Rates for *in vivo* control gonads are expressed as the mean of two observations, and the values for cultured gonads are expressed as the mean ± s.e.m. for four observations. ○, *In vivo* control ovaries; □, *in vivo* control testes; ●, ovaries; and ■, testes cultured from day 16 of gestation. *b*, 17β-oestradiol secretion into the culture medium. Media from either ovarian or testicular cultures were pooled separately when the media were changed (48 or 96 h). Each pooled sample was extracted with 5 volumes of ethyl ether and chromatographed on Celite columns as before[3]. Aliquots corresponding to 25% of the column eluates for 17β-oestradiol were assayed by radioimmunoassay[10]. Each sample represents the pooled media from 6–15 pairs of gonads, and the results are expressed as the mean and range of two experiments. ●, Ovaries; ■, testes.

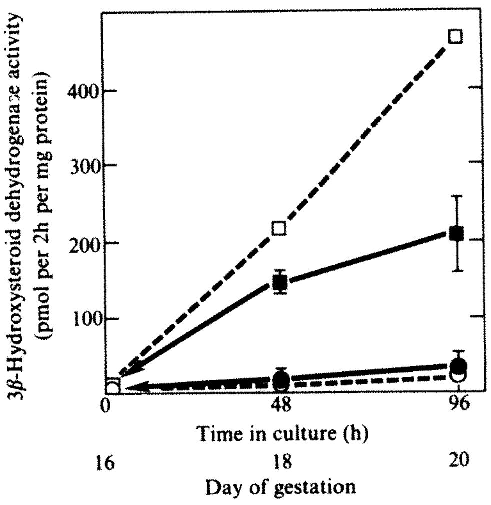

Fig. 2 3β-Hydroxysteroid dehydrogenase activity in cultured and control fetal rabbit gonads. 3β-Hydroxysteroid dehydrogenase activity was estimated by assessing the amount of androstenedione plus testosterone formed in the incubations of fetal gonads with 1,2-^{3}H-dehydroepiandrosterone described in the text and the legend to Fig. 1. ○, *In vivo* control ovaries; □, testes; ●, ovaries; and ■, testes cultured from day 16 of gestation. Data for *in vivo* control gonads represent the mean of two experiments, and data for the cultured gonads represent the mean ± s.e.m. of four observations each.

At day 16 of gestation neither fetal ovaries nor fetal testes synthesised 17β-oestradiol from ^{3}H-dehydroepiandrosterone (Fig. 1*a*). However, after 48 h in culture, fetal ovaries developed the capacity to form 17β-oestradiol at a rate equal to that in control ovaries of corresponding age (2.2 pmol per 2 h per mg protein in cultured ovaries; 2.1 pmol per 2 h per mg protein in day 18 *in vivo* control ovaries). The rate of 17β-oestradiol formation in cultured ovaries declined by 96 h to 1.15 pmol per 2 h per mg protein but remained substantially greater than the rate of formation in both cultured and day 20 *in vivo* control testes. Furthermore, after 48 and 96 h in culture, ovaries secreted four to six times more 17β-oestradiol per gonad into the medium than did testes (Fig. 1*b*), indicating that the observed enzymatic differentiation *in vitro* reflects a true functional oestrogen synthesis similar to that which occurs *in vivo*[10].

3β-Hydroxysteroid dehydrogenase activity was estimated by measuring androstenedione and testosterone formation from 1,2-^{3}H-dehydroepiandrosterone in the same fetal tissues used for the assessment of 17β-oestradiol formation. At the time of explantation (day 16 of gestation) 3β-hydroxysteroid dehydrogenase activity was low in both ovaries and testes (<3 pmol per 2 h per mg protein). There was a progressive increase in 3β-hydroxysteroid dehydrogenase activity in both ovaries and testes throughout the 4-day culture period (Fig. 2), although the final rate was greater in testes than ovaries (209 and 37 pmol per 2 h per mg protein, respectively).

Although the histological and enzymatic differentiation in culture of the fetal testis of rat[11] and rabbit[7] have been described before, our study shows for the first time the enzymatic differentiation of the fetal ovary in culture. ^{3}H-dehydroepiandrosterone was used as substrate to enable us to measure simultaneously the development of the rate-controlling enzyme for testosterone synthesis (namely 3β-hydroxysteroid dehydrogenase-$\Delta^{4,5}$-isomerase) and the capacity for 17β-oestradiol synthesis in the fetal rabbit gonad[6]. Although this procedure may underestimate the enzymatic capacity for oestrogen synthesis, the fact that the secretion of 17β-oestradiol into the medium by cultured ovaries parallels the increase in oestrogen formation from ^{3}H-dehydroepiandrosterone indicates that the differences in oestrogen formation between the fetal ovary and testis are real. Furthermore, similar measurements were obtained after short term incubation of fetal gonads when a saturating concentration of ^{3}H-testosterone was used as substrate for oestrogen synthesis[3].

The fact that endocrine differentiation of the fetal rabbit ovary, as well as the testis, occurs in organ culture at the same time that the process occurs *in vivo* suggests that the differentiation is inherent to the gonads and not controlled by extragonadal factors. Because enzymatic differentiation of the fetal ovary occurs earlier than would be predicted on the basis of histological criteria in rabbit[3], man[4] and sheep[5] it is possible that the onset of 17β-oestradiol synthesis is a prerequisite for other events in ovarian differentiation. If that is true, the genetic composition of the female may be responsible for the development of endocrine function in the female embryo, and the endocrine function in turn may be responsible for the histological differentiation of the ovary. Regardless of any endocrine implications, the demonstration that enzymatic markers for fetal ovaries and testes develop *in vitro* will be useful in the study of factors controlling gonadal differentiation.

Lactogenic receptor regulation in hormone-stimulated steroidogenic cells

Terry F. Davies*, Mohan Katikineni, Vivian Chan, James P. Harwood, Maria L. Dufau & Kevin J. Catt†

Endocrinology and Reproduction Research Branch, National Institute of Child Health and Human Development, NIH, Bethesda, Maryland 20205

Receptor sites for lactogenic hormones such as prolactin (PRL), human growth hormone (HGH), and placental lactogens, are widely distributed in mammalian tissues, including mammary glands[1], steroid-secreting cells of the adrenal, testis, and ovary, and target cells of steroid hormone action such as liver, prostate, and kidney[2,3]. Although the biological functions of lactogen binding sites remain uncertain, a relationship between prolactin and lipoprotein metabolism is implied by the occurrence of prolactin receptors in steroidogenic cells of the gonads and adrenal, and by the ability of prolactin to increase esterified cholesterol in the testis[4]. Recently, loss of testicular prolactin receptors has been observed following elevation of circulating luteinising hormone (LH) concentrations by the gonadotropin releasing hormone (GnRH) and its agonist analogues[5,6]. The hormone dependence of lactogen receptor sites in steroid-secreting cells was further analysed in rat testis, ovary, and adrenal glands after treatment with the respective trophic hormones, gonadotropin and ACTH. In each of these tissues, rapid and transient loss of lactogen receptors was observed after trophic hormone stimulation. These findings indicate that increased turnover of lactogen receptors is an important component of the target-cell response, and suggest that prolactin receptors might be involved in the transport of lipoprotein precursors for steroid biosynthesis.

Previous studies have shown that treatment with exogenous gonadotropins such as ovine LH (oLH) or human chorionic gonadotropin (HCG) causes marked and prolonged reduction of testicular LH receptors[7–9]. This process of receptor depletion, commonly referred to as down-regulation, is analogous to the effects of other peptide hormones, such as insulin and growth hormone, on their specific receptor sites[10,11]. We have recently observed that lactogen receptors in the testis initially undergo changes in parallel with those of LH receptors after gonadotropin treatment. An early brief rise in both receptor sites is followed by a marked and transient decrease of lactogen receptors after administration of oLH or HCG[12]. An example of the concomitant loss of testicular LH and lactogen receptors after treatment with gonadotropins is shown in Fig. 1. The lactogen receptors were decreased by 70% at 24 h, and returned to normal values at 48 h, whereas LH receptors fell rapidly and remained low for up to 96 h. The reduction in lactogen binding followed the peak of testosterone secretion, which normally occurs within 4 h after administration of either GnRH or exogenous gonadotropin. The disappearance of lactogen receptors was not due to occupancy of the binding sites by endogenous hormone, since no significant increase in serum prolactin was detected by radioimmunoassay after LH treatment. In addition, no change in degradation of labelled HGH was observed in testis fractions prepared from gonadotropin-treated rats.

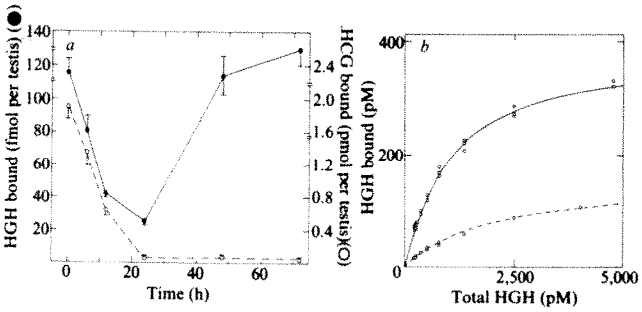

Fig. 1 *a*, Transient loss of lactogenic hormone binding sites in adult rat testes stimulated *in vivo* by administration of 20 µg HCG. A 15,000*g* fraction of testis homogenate was analysed for receptor binding capacity with ^{125}I-HGH and ^{125}I-HCG to quantitate lactogenic and LH receptors, respectively[6,20]. The use of HGH tracer to measure lactogen receptors was based on the ability of HGH to bind specifically to receptors for prolactin and other lactogens[1]. In this and subsequent figures, each point represents the mean ± s.e. of data from groups of six rats. The mean ± s.e. for the control animals throughout the study are shown in double horizontal bars on the vertical axes. *b*, Saturation curves for ^{125}I-HGH binding to 15,000*g* fractions of homogenates from control testes (continuous line) and testes removed 24 h after administration of 100 µg oLH (broken line).

---

Table 1 Insulin receptors in the rat ovary during stimulation with HCG

Time after injection with HCG	Insulin receptors (fmol per mg protein; mean ± s.e.)
0 (control)	38.8 ± 0.35
6 h	37.4 ± 1.5
12 h	37.9 ± 7.9
24 h	35.6 ± 0.3
48 h	27.4 ± 4.5

Primed rats were injected subcutaneously with 20 μg of HCG and groups of three rats were sacrificed at the times indicated. Pairs of ovaries were assayed for insulin receptor sites using ^{125}I-insulin. Two aliquots in duplicate of the 15,000g pellet of ovarian membranes were incubated for 16 h at 4 °C with 1.27×10^{-10} M insulin, specific activity 1,325 c.p.m. per fmol. Similar aliquots were incubated in the presence of 5×10^{-7} M unlabelled insulin to determine nonspecific binding.

In the luteinised rat ovary, similar changes in lactogen receptors were observed after gonadotropin treatment. When immature rats, primed with pregnant mare serum gonadotropin (PMSG) and HCG to induce luteinisation of the ovaries[13], were treated with 20 μg HCG, the rapid and marked fall in LH receptor capacity was consistently accompanied by a decrease in binding of ^{125}I-HGH. This decrease in lactogen sites occurred earlier than in the testis and was again coincident with LH receptor loss between 6 and 24 h. The lactogen receptors had returned to normal at 48 h, whereas marked loss of LH receptors persisted for 3 d (Fig. 2). During these gonadotropin-induced changes in lactogen receptors, there was no alteration in the concentrations of two other luteal cell receptors, for insulin and β-adrenergic ligands. As shown in Table 1, insulin receptors in the luteinised ovary remained constant after HCG treatment that caused marked decreases in LH and lactogen receptors. There was a similar lack of effect of HCG treatment on β-adrenergic receptors, which have recently been shown to be functionally coupled to adenylate cyclase and progesterone secretion in the luteal cell[14].

Gonadal lactogenic hormone receptors, like those for LH, are located on the steroidogenic cells of the testis[15] and ovary[16]. The common location of testicular LH and prolactin sites, and the similarity in their rates of depletion after GnRH or LH/HCG treatment, suggest that down-regulation of the two receptors is coordinated after gonadotropin stimulation, and that the two receptors could be physically related within the target cell membrane. Although the LH and prolactin sites are highly specific for the respective ligands, the molecular weights of the two receptors are similar after detergent solubilisation (about 200,000)[17,18]. This was further examined by simultaneous gel filtration of the two binding sites on 6% agarose after extraction from testis interstitial particles with 1% Triton X-100. Subsequent binding assay of the free receptors in each fraction with ^{131}I-HCG and ^{125}I-HGH revealed two coincident peaks of hormone-binding activity with K_{av} of 0.31, consistent with a molecular radius of about 6.8 nm for each of the detergent-solubilised hormone receptors.

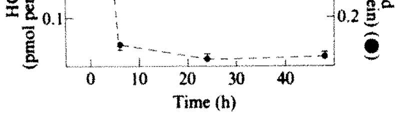

Fig. 2 Binding of lactogen (HGH) (○) and gonadotropin (HCG) (●) to the 15,000g fraction of homogenates from luteinised rat ovaries after subcutaneous treatment with 20 μg HCG given 8 d after priming with PMSG and HCG. Binding assays were performed as previously described[6,13].

In the adrenal cortex, prolactin receptors have been localised to the reticularis and fasciculata zones[19]. Following treatment of male rats with corticotropin (ACTH$_{1-24}$), we observed a marked reduction in adrenal lactogen binding between 6 and 12 h after injection of the hormone (Fig. 3). Although the return of adrenal receptors was more rapid than in the testis and ovary, the initial phase of receptor loss was again subsequent to the peak of steroid (corticosterone) secretion, which usually occurs within 60–90 min of ACTH administration.

The decreased binding of HGH tracer by steroid-secreting cells of the gonads and adrenal after hormonal stimulation was shown by analysis of the data[20] to result from loss of lactogen receptors, rather than a change in the association constant (Table 2). In addition, hormone-induced depletion of lactogenic sites appeared to be cell-specific, since gonadotropin in stimulation had no effect on adrenal or prostatic lactogen binding, and ACTH did not alter the testicular lactogenic sites. As noted above, prolactin receptor loss was not attributable to elevated serum prolactin levels. Recently, a rapid and transient phase of prolactin receptor loss has been described in the mammary gland and liver[21] after treatment with large doses of prolactin, preceding the rise in receptor concentration that results from long-term prolactin treatment[22]. However, the reduction of lactogenic hormone sites we observed after heterologous hormone treatment presumably involves loss of unoccupied binding sites, in contrast to the usual form of receptor down-regulation in which occupancy initiates receptor loss by processing or degradation.

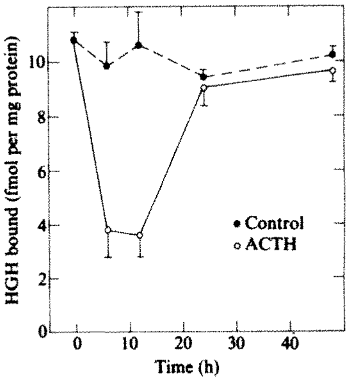

Fig. 3 Rapid loss and recovery of lactogen binding sites in rat adrenal glands after treatment with 10 units of ACTH$_{1-24}$ (○) compared with binding to control adrenals from untreated rats (●). After decapsulation, adrenal glands were homogenised prior to binding analysis with ^{125}I-HGH.

Several explanations can be suggested for these observations on the rapid regulation of lactogenic receptors in steroid-secreting cells. In the gonads, the similar molecular size and coordinate regulation of the LH and lactogen receptors is compatible with a close physical relationship between the two sites. However, while occlusion of the lactogenic sites could be envisaged during occupancy of the gonadotropin receptors, no such cross-reaction has been observed during specificity studies on LH and prolactin receptors. Also, the more rapid return of the lactogenic sites demonstrates their ability to vary independently of LH receptors. It is also conceivable that the loss of prolactin receptors after hormonal stimulation of the gonads and adrenal is part of a more generalised effect on plasma membrane receptor turnover. However, this possiblity is rendered unlikely by the absence of changes in luteal cell receptors for insulin and catecholamines during HCG-induced loss of lactogen receptors.

The receptor loss observed after *in vivo* stimulation of steroidogenesis may be related to an effect of high steroid concentration at the cell membrane, since reduction of adrenal

Table 2 Characterisation of lactogenic binding sites in steroid secreting cells in the basal and stimulated state

Receptor location (treatment)	Equilibrium association constant ($K_a \times 10^9$ M^{-1})*		Binding capacity for HGH (fmol per mg protein)*

and kidney prolactin receptors follows high dosage treatment with dexamethasone and sex steroids[23]. However, the loss of prolactin receptors in hormone-stimulated gonads and adrenals occurs after the phase of steroid secretion, and is not prevented by treatment with inhibitors of steroidogenesis (unpublished observations). A transient steroid-induced blockade of protein synthesis could also contribute to lactogen receptor loss, since hepatic prolactin receptors undergo transitory loss after cycloheximide treatment[24], and the early actions of ACTH have been shown to include decreased protein synthesis in the adrenal gland[25].

The most likely explanation of lactogen receptor loss is that stimulation of internalisation is a consequence of trophic hormone action on the steroidogenic target cell[26]. Such internalisation of prolactin receptors may be an important consequence of the activation process, particularly if related to the uptake of precursors for steroidogenesis. This mechanism need not be responsible for provision of the cholesterol immediately metabolised during hormone-induced steroid secretion, but would be important for the long-term maintenance of precursor pools within the target cells of the gonads and adrenal. The major substrate for biosynthesis of steroid hormones in the testis, ovary and adrenal glands of the rat is circulating lipoprotein cholesterol, rather than cholesterol that is newly synthesised within the steroid secreting cell[27]. In rats, high density lipoproteins bind to the steroidogenic cell membrane[28] and may be internalised as described for the low density moiety in human cells[29].

A prolactin receptor-mediated mechanism controlling lipoprotein transport would be consistent with the relationship between prolactin and cholesterol metabolism in the gonads[4], and with the high content of prolactin receptors in the ovary, testis, and adrenal gland. Recently, the prolactin molecule has been demonstrated within ovarian luteal cells and adrenal fasciculata cells[30], presumably after receptor binding and internalisation. Furthermore, in the hepatocyte, where lipoprotein synthesis occurs[31], prolactin receptors undergo rapid turnover[24] and a high proportion of the sites are intracellular[32]. In the lactating mammary gland, where lipoproteins are actively metabolised, prolactin receptors are abundant[1] and have been detected within epithelial cells[33]. This evidence for the presence of prolactin receptors within sterol metabolising cells, with the present finding of increased receptor turnover after hormone stimulation, is consistent with the proposal that prolactin receptors could be involved in a mechanism for regulating the entry of lipoprotein precursors in to steroid secreting cells.

We thank Maxine Lesniak for providing the ^{125}I-insulin used for assay of ovarian insulin receptors.

HLA-restricted T-cell recognition of Epstein–Barr virus-infected B cells

A. B. Rickinson, L. E. Wallace & M. A. Epstein

Department of Pathology, Medical School, University of Bristol,
Bristol BS8 1TD, UK

In mice the cytotoxic T-cell response to several types of virus is influenced by genes within the major histocompatibility complex[1–5]; in particular, genetic control is exercised at the effector cell level through a requirement that virus-specific cytotoxic T cells recognise viral antigens in association with H-2K and H-2D region gene products on the surface of infected cells[1,2]. In man the restriction which the analogous HLA-A, -B and -C-region gene products might place on virus-specific T-cell function is still in dispute. The earliest and most controversial evidence concerns the Epstein–Barr virus (EBV), a B lymphotropic agent which causes infectious mononucleosis[6] (IM) and which induces an unusually vigorous T-cell response[7]; cytotoxic T cells from IM patients' blood were shown to be EBV-specific, yet, in contrast to mouse systems, apparently free of any obvious HLA restriction[8,9]. Since then T-cell recognition of EBV-infected B cells has assumed particular significance as a model system for the study of cytotoxic T-cell function in man. This report describes the results of a new approach clearly indicating that HLA-A and -B region products do indeed have a role in this system.

During recent experiments monitoring the ease of establishment of EBV-transformed B-cell lines from cultures of adult donor leukocytes exposed to the virus *in vitro*, it was found that cultures from non-infected (seronegative) individuals regularly gave rise to cell lines, whereas in the corresponding cultures from previously-infected (seropositive) donors the early proliferation of virus-infected B cells was halted by a T-cell dependent mechanism[10]. All the available evidence suggested that this regression of growth was occurring through the reactivation *in vitro* of a pool of EBV-specific cytotoxic T-cell precursors present exlusively in the blood of seropositive individuals[11,12]. In

0028–0836/80/090865—03$01.00

the experiments reported here T cells collected from regressing cultures have been tested for their ability to inhibit the outgrowth of EBV-transformed B cells of the autologous line and of HLA-related and unrelated allogeneic lines.

Ten healthy adult donors of known HLA type and of known serological status with respect to EBV were used. Experimental procedures were as previously described[10–12]. From each 60-ml blood sample, 7×10^6 mononuclear cells were used in a microtest plate assay for which the cells were exposed to EBV, or to culture medium as a control, before seeding in 0.15-ml volumes into microtest plate wells at one of a range of concentrations (2×10^6 to 1.25×10^5 cells per ml); the cultures were then observed for 28 d to assess the 'strength' of regression for each donor in terms of the minimum initial concentration required for a 50% incidence of the effect among replicate cultures[10]. The remaining mononuclear cells were exposed to EBV, cultured at 2×10^6 per 2-ml well and then 10–14 days later the cultures were collected and the T-cell subpopulation prepared. Aliquots of 10^5 T cells were then added to microtest plate wells containing known numbers (ranging from 2×10^5 to 2.5×10^2) of autologous or of allogeneic EBV-transformed target cells of known HLA type; three to five replicate wells were set up for each particular combination, along with parallel cultures of target cells alone. After 2 weeks the incidence of successful outgrowth of the target cells could be scored unequivocally[12] and, for each particular effector and target cell combination, the growth inhibitory effect of the T cells was expressed as the ratio of that number of target cells required for a 50% incidence of successful outgrowth in the presence of T cells, to that number required in cultures of target cells alone.

Table 1 summarises the data from all 10 donors studied. The results clearly emphasise the immunological basis of regression in that the effect was consistently observed in cultures set up from all seven seropositive donors tested, with individual donors tending to show either strong (CA, SG, BW) or somewhat weaker (MM, AR) responses on repeated testing, but was never seen in cultures from the seronegative donors. This pattern of results was exactly reflected in the co-cultivation assay where T cells collected from seropositive donor cultures just before their regression consistently showed a marked inhibition of outgrowth of the autologous EBV-transformed cell line, whereas very little growth inhibition was apparent in the corresponding co-cultures from three seronegative donors.

Allogeneic cell lines used as targets in the co-cultivation assay were likewise hardly affected by the addition of T cells from seronegative donor cultures; in contrast effector cells from seropositive donor cultures did in some cases cause significant inhibition, although this was almost invariably less than that mediated by these same cells against their autologous cell line. Using the degree of autologous target cell inhibition within each experiment as a standard, the relative inhibition suffered by allogeneic cell lines was analysed in the light of their known HLA-A, -B and -C antigen expression. This approach revealed an underlying pattern in the results which is illustrated by the representative data shown in Fig. 1 from three seropositive donors, CA, MM and SG. Whilst an analysis in relation to HLA-C antigen expression is difficult in view of the incomplete typing at this locus, there are strong indications that sharing of HLA-A or -B antigens between effector and target cells predisposes towards significant cross-reactivity. Thus inhibition of

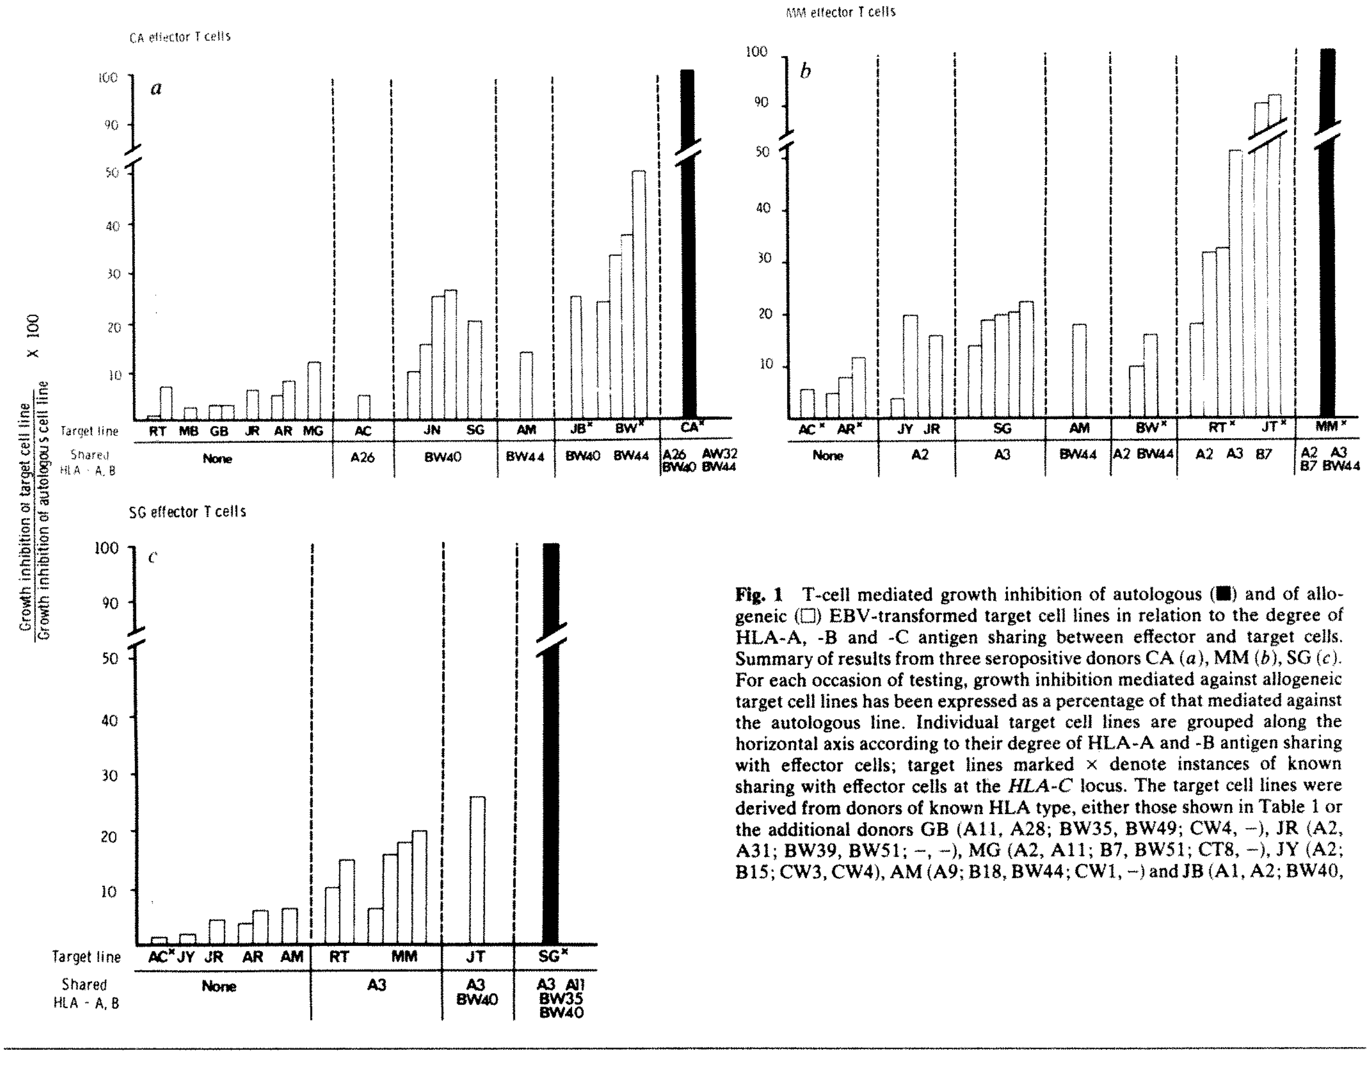

Fig. 1 T-cell mediated growth inhibition of autologous (■) and of allogeneic (□) EBV-transformed target cell lines in relation to the degree of HLA-A, -B and -C antigen sharing between effector and target cells. Summary of results from three seropositive donors CA (*a*), MM (*b*), SG (*c*). For each occasion of testing, growth inhibition mediated against allogeneic target cell lines has been expressed as a percentage of that mediated against the autologous line. Individual target cell lines are grouped along the horizontal axis according to their degree of HLA-A and -B antigen sharing with effector cells; target lines marked × denote instances of known sharing with effector cells at the *HLA-C* locus. The target cell lines were derived from donors of known HLA type, either those shown in Table 1 or the additional donors GB (A11, A28; BW35, BW49; CW4, –), JR (A2, A31; BW39, BW51; –, –), MG (A2, A11; B7, BW51; CT8, –), JY (A2; B15; CW3, CW4), AM (A9; B18, BW44; CW1, –) and JB (A1, A2; BW40,

* Antibody status with respect to EBV was determined by the anti-virus capsid antigen immunofluorescence test as described elsewhere[10].

† Typing at the HLA-A, -B and -C loci was carried out on freshly isolated blood mononuclear cells at the National Tissue Typing Reference Laboratory. Undefined *C* locus antigens are shown as blanks.

‡ The minimum initial cell concentration for a 50% incidence of regression was calculated from the incidence of transformation and/or regression seen in replicate cultures in the 4-week microtest plate assay[10]. Mononuclear cells were exposed either to culture medium alone or to an EBV preparation (10^5 50% transforming doses per ml) from B95-8 culture supernatant before seeding in 0.15-ml volumes into microtest plate wells (Nunc) at 2×10^6, 10^6, 5×10^5, 2.5×10^5 and 1.25×10^5 cells per ml and culturing for 4 weeks. The figure given for each donor is the mean of those obtained in the number of experiments shown. A value of $>2\times10^6$ cells per ml indicates that regression was not seen in any of the cultures.

§ EBV-infected mononuclear cell cultures in 2-ml wells (Linbro) were collected 10–14 d post infection and dead cells removed by a preliminary centrifugation for 30 min at 400*g* on Ficoll-Hypaque. The T-cell subpopulation was then prepared by rosetting with AET-treated sheep erythrocytes according to the method of Gmelig–Meyling and Ballieux[22] and the rosetted cells rescued by lysis of the erythrocytes in 0.75% NH_4Cl in 0.016M Tris buffer, *p*H 7.25, at 4 °C. Aliquots of 10^5 such T cells were added to replicate microtest plate wells containing known numbers (2×10^5, 10^5, 5×10^4, 2.5×10^4, 10^4, 5×10^3, 2.5×10^3, 10^3, 5×10^2 and 2.5×10^2) of target cells of the autologous EBV-transformed B-cell line and the incidence of successful target cell outgrowth was recorded after 2 weeks[12]. T-cell mediated growth inhibition was expressed as the ratio of that number of target cells required for a 50% incidence of successful outgrowth in the presence of T cells to that number required for successful outgrowth in cultures of target cells alone. The figure given for each donor is the mean of those obtained in the number of experiments shown.

growth over and above that seen against HLA-unrelated targets was consistently found in some, though not all, examples of a single shared antigen (for example, reciprocal recognition of MM and SG through shared A3, Fig. 1*b*, *c*), whereas more extensive antigen sharing was almost always associated with an enhanced cross-reactivity. For instance, the recognition of BW targets by CA effectors through shared BW40, BW44 (Fig. 1*a*) and of JT targets both by SG effectors through shared A3, BW40 (Fig. 1*c*) and by MM effectors through A2, A3, B7 (Fig. 1*b*) was in each case confirmed by the reciprocal target and effector cell combination (data not shown).

It seems most unlikely that results of this type could have arisen by chance or could be explained on the basis of differences in the essential sensitivity to growth inhibition *per se*. Thus, whilst individual results from such a small sample of randomly selected donors must be interpreted cautiously, the overall data are consistent with the concept of an HLA-related T-cell cytotoxicity similar to that recently reported for influenza virus-specific human T cells, again studied after secondary stimulation *in vitro*[13]. Furthermore, the apparent relationship between the magnitude of effector cell function and the extent of HLA antigen sharing with target cells suggests that the effector cell population contains a number of independent clones, each recognising the target antigen in association with one particular HLA region gene product. Within this framework there are individual examples of poor recognition despite HLA antigen sharing (for example, CA effectors and AC targets sharing A26, Fig. 1*a*) and such exceptions, perhaps related to those now being recognised in the influenza virus system[14–16], require further investigation.

The rapid inhibition of growth caused by effector T cells in the co-cultivation assay[12] is almost certainly a consequence of their direct cytotoxic action. Thus chromium release assays carried out in this[17] and in another[18] laboratory have now shown that effector T cells from regressing cultures are both cytotoxic and EBV-specific, as they kill autologous EBV-transformed cells but not autologous pokeweed mitogen-stimulated B lymphoblasts or cells of the K562 cell line, a sensitive indicator of nonspecific natural killer cell activity[19]. If, as seems likely, these reactivated T cells recognise the same EBV-associated cell surface change as do primary effector T cells present in the blood of acute IM patients (that is, the lymphocyte-detected membrane antigen, LYDMA[8]) it becomes important to re-examine the possibility of HLA-related constraints governing IM T-cell cytotoxicity[20,21]. Certainly this work and other independent studies[18] strongly suggest that cytotoxic T cells reactivated *in vitro* do indeed recognise an EBV-associated LYDMA-like antigen in conjunction with HLA-A and -B region gene products on the surface of infected B cells. This conclusion is strengthened by our most recent experiments demonstrating that such recognition can be specifically blocked by pretreatment of the target cells with high titre preparations of monoclonal antibodies to a common determinant on HLA-Ag, -B and -C molecules.

We thank Dr C. Entwistle and Mr T. Ray of the National Tissue Typing Reference Laboratory for HLA-typing and Elizabeth Gough and Ann Green for technical help. This work was supported by the MRC (grant no. G 976/412) and was assisted by the Cancer Research Campaign out of funds donated by the Bradbury Investment Co. of Hong Kong.

Hyperpolarisation of rat peritoneal macrophages phagocytosing latex particles

J. Kouri, M. Noa, B. Diaz & E. Niubo

Centro Nacional de Investigaciones Cientificas, Havana, Cuba

The changes that take place in the plasma membrane during endocytosis are still poorly understood[1]. Studies of the electrical properties and related permeabilities of cells during pinocytosis and phagocytosis should provide insight into these changes. This approach has not been much exploited, although there have been a few relevant reports. For example, induction of pinocytosis in amoebae produces a marked decrease in plasma membrane resistance[2], and exposure of polymorphonuclear leukocytes to phagocytosable particles can engender alterations in ionic permeabilities[3]. The present report demonstrates that the induction of phagocytosis in rat peritoneal macrophages is accompanied by a sustained hyperpolarisation of the cells.

Macrophages were obtained by the implantation of agar-coated sterile Teflon disks in the peritoneal cavities of Wistar rats[4]. After 3 d the disks were removed and placed in Tyrode solution (NaCl, 124 mM; KCl, 3 mM; $CaCl_2$, 2.5 mM; $MgCl_2$, 1.2 mM; $NaHCO_3$, 15 mM; NaH_4PO_4, 1.2 mM; glucose, 5 mM, *p*H 7.4, kept at 37 °C with 95% O_2–5% CO_2 bubbling through). The disks were placed in an electrophysiological chamber and macrophages were selected with an inverted phase microscope. The cells were penetrated with glass microelectrodes of less than 0.5 μm diameter filled with 3 mM KCl. Electrode resistances were in the range of 20–50 MΩ and tip potentials were less than 5 mV. The microelectrodes were coupled through a high impedence compensator to a differential preamplifier MZ4 (Nihon–Khoden) and a VC-8 oscilloscope (Nihon-Khoden). Records were photographed with a cine camera running at velocities of 10 or 20 mm s^{-1}.

As in previous work by our laboratory[5–7], most of the cells penetrated showed distinct, negative potentials (Fig. 1*a*) which disappeared when the electrodes were withdrawn. For the 200 cells studied in the present work, the mean potential was −13 ± 4.7 (s.d.) mV. The potentials were stable for more than 30 min, but disappeared on addition of 2 mM NaF or 2.5 mM DNP. They were similar to the potentials we have obtained previously, and to those reported for macrophages of other species[8,9] and for other non-excitable cells[10–14]. Occasionally cells in our preparations showed positive potentials whose nature is under study and will not be discussed here.

Difco latex (0.8 μm diameter spheres, washed and diluted 1:10 in phosphate-buffered saline: NaCl, 137 mM, KCl, 2.7 mM, buffered at *p*H 7.2–7.4 with 10 mM sodium phosphate) was added to the disks in the chamber (0.06 ml of latex added to 20 ml of Tyrode). Latex induces extensive phagocytosis which persists for at least 20–30 min[15]. During this time, approximately 10 particles per cell are taken up. Latex was added to impaled cells 2–3 min after they had been penetrated. When this was done there was a rapid hyperpolarisation (Fig. 1*b*) followed by a gradual hyperpolarisation which reached a maximum at 15–30 min (Fig. 1*c*). The mean initial potential measured in the first minute after exposure to latex was −25 ± 3.2 and the eventual hyperpolarisation was to −46 ± 5.1 mV (40 cells). After 20–30 min, the membrane depolarised towards the prestimulation level (Fig. 1*d*). In 80% of the cells responding to latex we have observed short trains (< 1 s) of small (up to 5 mV) brief depolarisations and hyperpolarisations or slower oscillations of up to 2 mV and 3 s duration, superimposed on the longer term hyperpolarisation. Addition of phosphate-buffered saline without latex or of a drop of Tyrode solution does not provoke changes in the membrane potential.

Gallin and coworkers[8,9] working on macrophages of other species have reported transient hyperpolarisations occurring spontaneously and in response to chemotactic factor isolated from serum. They have suggested that the hyperpolarisations might reflect increased permeability to potassium, perhaps through events in which calcium is involved. When we increased the concentration of calcium in our medium to 3.8 mM we observed an increase in the mean potential measured in unstimulated cells to −20 ± 2.2 mV (30 cells). With such cells latex evokes hyperpolarisation to −50 ± 4.3 mV (10 cells).

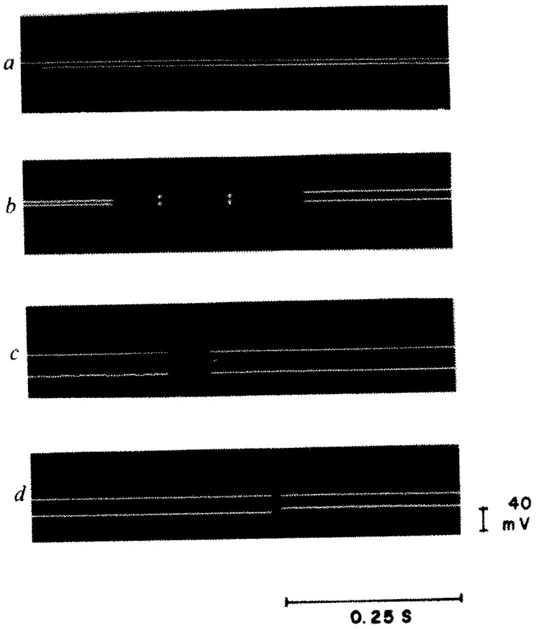

Fig. 1 Records obtained from the same cell at different stages in the response to latex. *a*, Entry of the electrode into the cell. *b*, Addition of latex. The traces on the left show the potential just before the addition of latex. The camera was then stopped, advanced two frames (producing the two pairs of dots to mark the time of addition of latex), latex was added and recording resumed 30 s later. The traces on the right thus show the potential 30 s after adding latex. A distinct hyperpolarisation has occurred. *c*, Potentials 15 (left) and 20 (right) min after adding latex. The camera was stopped between the two recording periods producing the gap in the record. Note the hyperpolarisation. *d*, Potentials 25 (left) and 30 (right) min after adding latex. The camera was stopped between the two recording periods producing the gap in the record. Note the decrease of the potential.

The present investigation and the studies cited above suggest that the early events in the induction of endocytosis include changes in the cell's permeability to ions. For granulocytes, it is reported that alterations in membrane potential can be induced by interaction of molecules that stimulate endocytosis with the cell surface; the potential changes do not require actual ingestion of the molecules[16], but whether this is generally the case is not known. It is too early for us to speculate in detail on the significance of the changes we observe or on how the permeability changes are related to the various stages of endocytosis or to the properties of the cell-surface receptors involved (presumably in our case, relatively nonspecific receptors[1] are involved). However, given the many parts evidently played by ions such as Ca^{2+}, K^+ and so forth in controlling the distribution or functional state of such cellular elements as contractile proteins, there are many possibilities for their participation in influencing endocytic processes. In any event, the work reported

0028–0836/80/090868—02$01.00

here suggests that electrophysiological techniques will prove useful in future analyses of cell-surface changes related to endocytosis by mammalian cells.

We thank E. Holtzman for helping prepare the manuscript.

Electrophysiological responses of *Didinium nasutum* to *Paramecium* capture and mechanical stimulation

Ritsuo Hara & Hiroshi Asai

Department of Physics, Waseda University, Okubo, Shinjuku-ku, Tokyo 160, Japan

***Didinium nasutum* is a carnivorous ciliate with a preference for feeding on species of *Paramecium*. Accidental contact between a *Paramecium* and the proboscis of a hungry *Didinium* (Fig. 1*a*) causes instantaneous discharge of extrusive organelles from the proboscis. If the strike is successful, some of these organelles penetrate the *Paramecium*, which immediately stops swimming and discharges many trichocysts, mostly from the struck side (Fig. 1*b*). Cytoplasmic streaming pulls the discharged organelles inward, the captured *Paramecium* reaches the proboscis, and then the *Didinium* swallows the prey, opening its proboscis[1–10] (Fig. 1*c* and *d*). On the other hand, a hungry *Didinium* does not discharge extrusive organelles when it collides with a glass wall. Instead it shows an avoiding reaction. When a *Paramecium* collides with the proboscis of a fed *Didinium*, the proboscis similarly does not discharge extrusive organelles, and the fed *Didinium* makes an avoiding response. We found that a hungry *Didinium* held steady by two glass capillary microneedles performed normal capture and ingestion in a solution containing *Paramecium caudatum*. We describe here an electrophysiological investigation of *Didinium nasutum* in collision with *P. caudatum* or with a glass rod while held still by glass capillary microneedles.**

Methods of stimulation and recording were similar to those used by Naitoh and Eckert for electrophysiological investigations of *Paramecium*[11]. Typical results are shown in Fig. 2. Accidental contact between a *Paramecium* and the proboscis of a fixed hungry *Didinium* generated a transient hyperpolarising potential of the *Didinium* cell, followed by a depolarising action potential associated with discharge of the extrusive organelles (Fig. 2*a* and *b* and Fig. 2*c* and d_2). The peak of the depolarising potential corresponded to completion of the discharge of the extrusive organelles. Subsequently, the membrane potential returned slowly to resting level. Marked fluctuations of the membrane potential often occurred during this period (Fig. 2*c* and d_2). Weak reversals of ciliary movement were associated with depolarisations of small magnitude. On rare occasions after discharging extrusive organelles, *Didinium* failed to capture the target organism, possibly because of a poor hit. *Didinium* then simply withdrew the discharged extrusive organelles. Even in this case, the changes in membrane potential were similar to those occurring in cases of successful capture.

Mechanical stimulation of the apex of the proboscis of a hungry *Didinium* with a glass rod induced a transient depolarising mechanoreceptor potential, which was followed by a depolarising action potential of the general membrane (Fig. 2*f* and *g*). No discharge of extrusive organelles was observed, but the *Didinium* showed ciliary reversal in response to this stimulation. A spontaneous action potential was often recorded in *Didinium* cells (Fig. 2d_1), and this also caused ciliary reversal.

In some cases, the proboscis of a fixed fed *Didinium* happened to collide with a new *Paramecium* about 5 min after ingestion of the previous prey. In such cases, the membrane responses were the same as for mechanical stimulation of the proboscis of a fixed hungry *Didinium* (Fig. 2*e*). Fed *Didinium* never discharged extrusive organelles, but responded to contact with *Paramecium* by ciliary reversal, in the same way as to a glass rod.

The proboscis membrane of a hungry *Didinium* seems to have a chemoreceptor that responds to contact with *Paramecium*, as well as a mechanoreceptor able to sense external mechanical stimulation. Chemoreception induces a hyperpolarising potential, and mechanoreception induces a depolarising potential. On the other hand, only the mechanosensitive system of the proboscis membrane is active in a fed *Didinium*. According to Naitoh and Eckert, mechanical stimulation of the anterior surface of *Paramecium* induces a mechanosensitive depolarising potential. In wild type cells a regenerative calcium action potential causing ciliary reversal is always accompanied by the anterior mechanoreceptor potential, caused by an increase in Ca^{2+} permeability after mechanical stimulation[12,13]. The responses of the proboscis surface of hungry *Didinium* to mechanical stimulation and that of the proboscis of fed *Didinium* to collision with a *Paramecium* are similar to the above responses of *Paramecium*.

The *Paramecium*-sensitive hyperpolarising potential and the depolarising action potential associated with discharge of the extrusive organelles were characteristic features of the prey capture behaviour of *Didinium*. The action potential was always

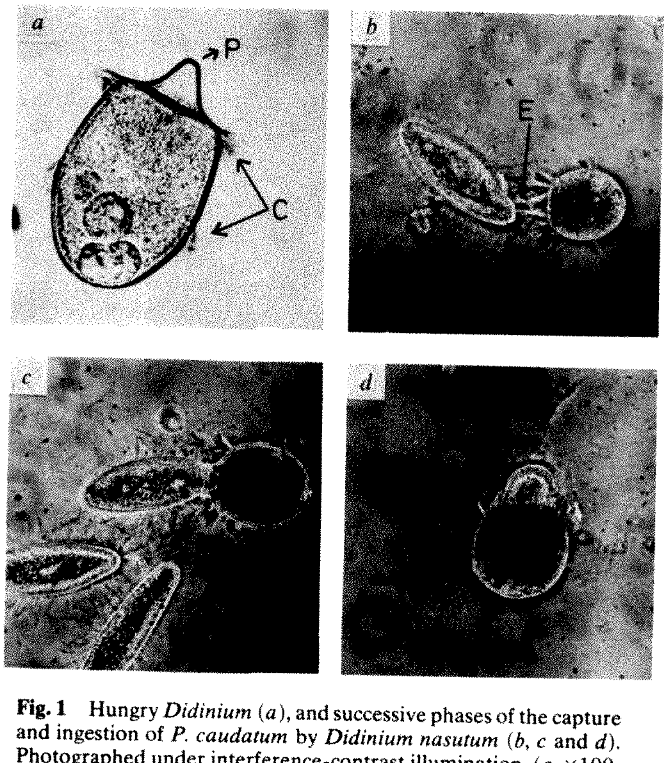

Fig. 1 Hungry *Didinium* (*a*), and successive phases of the capture and ingestion of *P. caudatum* by *Didinium nasutum* (*b*, *c* and *d*). Photographed under interference-contrast illumination. (*a*, ×100; *b*, *c* and *d*, ×50.) P, proboscis; C, cilia; EO, extrusive organelles.

0028-0836/80/090869—02$01.00

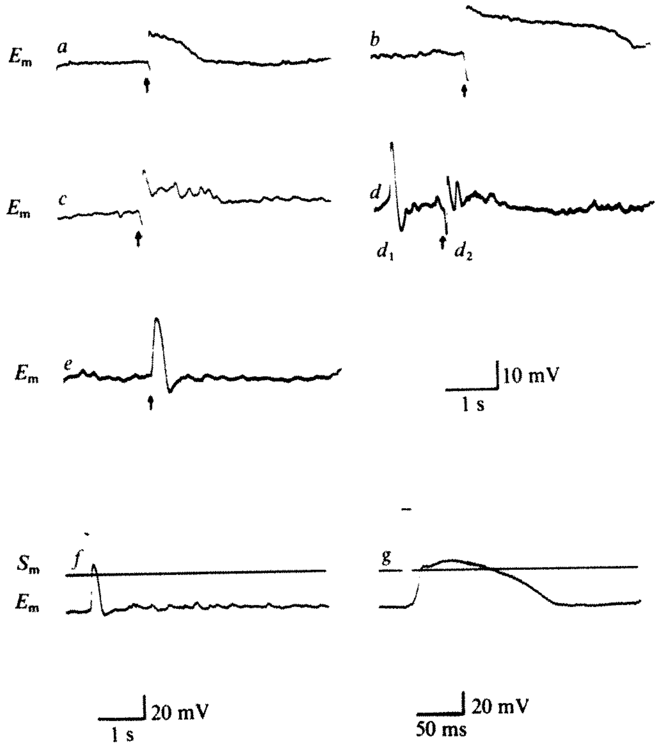

Fig. 2 Responses of the membrane potential to collision between *P. caudatum* and the apex of the proboscis of *Didinium nasutum* (*a*, *b*, *c*, d_2 and *e*). Arrows show the moment at which a *Paramecium* collided with the apex of the proboscis of *Didinium*. Spontaneous ciliary reversal response is also shown (d_1), together with responses to mechanical stimulation of the apex of the proboscis (*f* and *g*). *a*, *b*, *c*, *d*, *f* and *g*, hungry *Didinium*; *e*, fed *Didinium*. E_m, membrane potential; upward and downward deflections correspond to depolarisation and hyperpolarisation of the membrane, respectively. S_m, deflection in the trace indicates the duration and relative intensity of the electric pulse activating a piezoelectric crystal to drive a glass rod against the surface of the membrane. Membrane potentials were recorded in mixtures of 1 mM K^+, 1mM Ca^{2+} and 1 mM Tris–maleate (*p*H 7.0) (*a*, *b*, *c*, *d* and *e*) and 1 mM K^+, 1 mM Ca^{2+} and 1 mM Tris-HCl (*p*H 7.2) (*f* and *g*). All measurements were made at room temperature (20–25° C).

accompanied by the hyperpolarising potential. It seems likely that the discharge of extrusive organelles is associated with an inflow of Ca^{2+} through the proboscis membrane due to a sudden increase in Ca^{2+} permeability, enabling Ca^{2+} to flow inwards down its electrochemical gradient. This is because the discharge of extrusive organelles was always associated with the depolarising action potential, which was different from a general membrane depolarising action potential causing ciliary reversal, and membrane depolarisation in this species seems to involve an inflow of Ca^{2+}, as in the case of *Paramecium* in a mixture of 1 mM K^+ and 1 mM Ca^{2+}. It has been shown that the discharge of *Paramecium* trichocysts is associated with a flow of Ca^{2+} through the membrane[14].

We thank Professor Y. Naitoh, University of Tsukuba, for facilities and encouragement, and Mr H. Shiono for help.

Estimation of cytoplasmic and vacuolar *p*H in higher plant cells by ^{31}P NMR

Justin K. M. Roberts*, Peter M. Ray*,
Norma Wade-Jardetzky† & Oleg Jardetzky†

* Department of Biological Sciences, Stanford University, Stanford, California 94305
† Stanford Magnetic Resonance Laboratory, Stanford University, Stanford, California 94305

It has recently been emphasised that the intracellular *p*H of plant cells must be actively regulated to offset acid–base imbalances that occur during metabolism and solute uptake (for review see ref. 1). Changes in cytoplasmic *p*H might be important (1) in controlling various aspects of metabolism[2], including enzyme activities responsible for malate synthesis during cation accumulation[1,2], (2) in polar transport of the plant hormone, auxin[3], and (3) in intracellular responses to substances such as auxin and the phytotoxin fusicoccin, which cause proton extrusion[1,4,5]. Almost no direct measurements of cytoplasmic *p*H have been made on the small cells typical of higher plants[1]. The task is hampered by the presence of a generally acidic vacuole which occupies much of the cell volume. Use of the indirect method of ^{14}C-5, 5-dimethyloxazolidine-2, 4-dione (DMO) distribution is subject to considerable uncertainties because of corrections needed for vacuolar *p*H and volume, and DMO metabolism[6,7]. Here we report the use of ^{31}P nuclear magnetic resonance (NMR) to estimate the *p*H of vacuole and cytoplasm in maize root tips.

The observation of intracellular organic and inorganic phosphates by ^{31}P NMR has been proposed as a method for determining the internal *p*H of animal and microbial cells[8,9]. As the chemical shift (δ, the resonance frequency relative to a standard) of ^{31}P in these compounds yields a titration curve when plotted against *p*H (insert in Fig. 1), a determination of *p*H from a measured δ value is possible in principle. The advantage of the method is that it is noninvasive and nondestructive. The principal problem in its use is that *p*H may be the dominant, but is not the sole determinant, of δ. However, the resulting ambiguities are not severe, as will be discussed below.

Figure 1*a* shows a typical ^{31}P-NMR spectrum of maize root tips showing resonances from glucose-6-phosphate (G-6-P, peak 1) and inorganic phosphate (P_i, peaks 2 and 3). The

Table 1 ^{31}P-Chemical shifts observed in maize root tips, and corresponding *p*H values

	δ (p.p.m.) of peak relative to MDP			Corresponding *p*H values		
Treatment	1	2	3	1	2	3
Control	12.6	14.7	16.4	7.25	7.15	5.5
Control	12.65	14.7	16.4	7.1	7.15	5.5
Control	12.6	14.75	16.4	7.25	7.05	5.5

6 mM NH_4OH†	12.58	14.6	16.0	7.3	7.2	6.05
12 mM NH_4OH†	12.55	14.55	15.6	7.4	7.3	6.4

Control root tips were prepared and treated as for Fig. 1*a*. Columns headed 1, 2 and 3 refer to NMR peaks 1, 2 and 3 illustrated in the Figs 1 and 2.

* Root tips were incubated for 2 h in 50 mM 2-dG at 23 °C. *p*H value given for peak 1 is based on the titration curve of 2-dG-6-phosphate. Peak 2 was too small to be assigned a δ value in 2-dG-treated tissue.

† Root tips were incubated in 10 ml of 6 or 12 mM NH_4OH (initial *p*H 9.6) at 23 °C for 30 min (final *p*H 6.56 and 7.2, respectively).

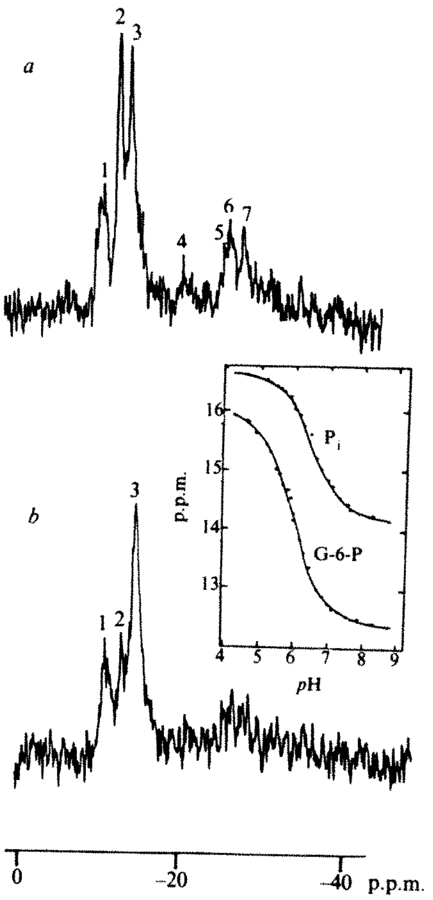

Fig. 1 *a*, 145.7 MHz ^{31}P-NMR spectrum of maize root tips (~900 tips or ~1.2 g) 1.5 mm long. Maize (*Zea mays* L.) WF9 × Bear 38 were soaked for 6 h in tap water, and grown for 2 days on moist tissue in the dark, at 25 °C. Plants were collected in the light, root tips 2–3 mm long being excised with a razor blade, and then put on ice. Before being placed in the NMR tube, they were washed three times with ice-cold distilled water. (Washing with 1 mM EDTA did not affect the quality of the spectra obtained.) Spectra were obtained at 5 °C with ~400 scans at 0.409 s per scan without proton irradiation and without lock using a modified Bruker HXS-360 spectrometer. Shifts are referenced to 0.05 M methylene diphosphonic acid (MDP) in *p*H 8.9 Tris buffer, located in a coaxial capillary tube. *b*, Spectrum of root tips 2.5 mm long, grown and prepared as *a*. Peak 1, G-6-P; 2, cytoplasmic P_i; 3, vacuolar P_i; 4 and 5, ATP; 6 and 7, UDP-Glc.

individual peaks can be identified on the basis of the relative chemical shifts and the published analyses of phosphate compounds in growing plant tissues[10–13]. Enzymatic analysis[14] of maize root tip perchloric extracts confirms that G-6-P is the predominant hexose phosphate.

The resonance due to G-6-P in maize root tips has a δ value corresponding to *p*H 7.1–7.25 (Table 1). Because G-6-P is an important cytoplasmic metabolite, and is not considered to form a significant storage pool, the G-6-P resonance probably reflects the *p*H of the cytoplasm. The positions of the two clearly resolvable peaks in the P_i region of the spectrum correspond to P_i at *p*H 7.05–7.15 (peak 2) and *p*H 5.5 (peak 3). This suggests that we are detecting resonances from two separate compartments in these cells—cytoplasm (*p*H ~ 7.1) and vacuole (*p*H ~ 5.5) These inferences are suported by the following observations:

(1) A spectrum (Fig. 1*b*) obtained from longer root segments, which contain much more highly vacuolate cells, shows much smaller peaks 1 (G-6-P) and 2 (cytoplasmic P_i), relative to peak 3 (vacuolar P_i), than are seen in root tips (Fig. 1*a*), the cells of which contain relatively more cytoplasm. In the more vacuolate tissue (Fig. 1*b*) the peaks corresponding to other important ^{31}P-containing cytoplasmic metabolites (ATP, UDP-Glc) are also reduced. A highly vacuolate tissue, such as the coleoptile of maize, yields only one ^{31}P resonance, corresponding to P_i at *p*H 5.5, that is, peak 3 (data not shown).

(2) When a root tip sample is aged at ~5 °C for 2–3 h in a closed (and thus anaerobic) NMR tube, peak 1 (G-6-P) decreases and peak 2 (cytoplasmic P_i) increases correspondingly, without much change in peak 3 (vacuolar P_i) (Fig. 2*a*, *b*). This presumably reflects depletion of G-6-P, as is known to occur in conditions of oxygen starvation[10,11], with release of P_i but without loss of the normal compartmentation of the cells. When tissue is similarly aged for 7–8 h the G-6-P peak disappears entirely, and the two P_i peaks (2 and 3) merge into a single peak that has a δ value intermediate between the two (not shown). This is to be expected as the cell die and their internal compartmentation breaks down.

(3) If root tips are incubated with 2-deoxyglucose (2-dG), a large ^{31}P resonance in the sugar–phosphate region appears (Fig. 2*c*). This peak can be attributed to 2-dG-6-phosphate, the principal metabolite formed when cells take up 2-dG[15,16]. Concomitantly, peak 2 (cytoplasmic P_i) virtually disappears, whereas peak 3 (vaculor P_i) remains strong. This corresponds with the expectation that cytoplasmic P_i will be used to phosphorylate 2-dG in the cytoplasm, where hexokinase is located.

(4) When root tips are incubated in dilute solutions of the permeant base, ammonia, the δ values of peaks 1 and 2 show little change, whereas that of peak 3 changes substantially,

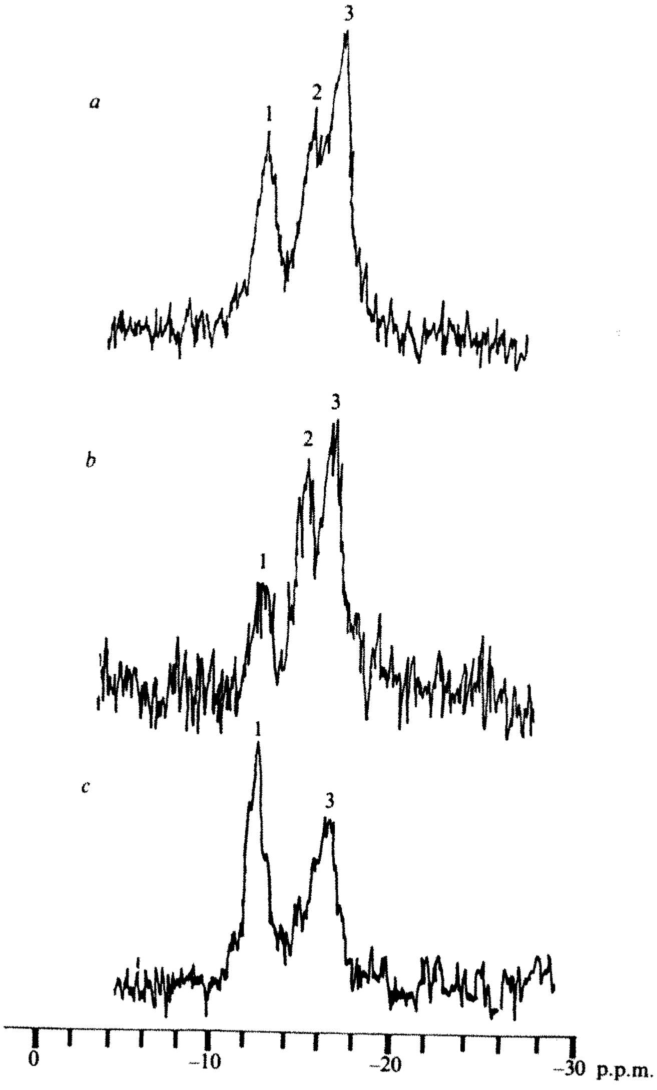

Fig. 2 ^{31}P-NMR spectra obtained from: *a*, maize root tips prepared as in Fig. 1*a*. *b*, The same root tips sample as in *a* after 2 h at 0–5 °C in the NMR tube; peaks 1, 2 and 3 as in Fig. 1*a*. *c*, Root tips that had been incubated in 50 mM 2-dG for 2 h at 23 °C; peaks 1, 2-dg-6-phosphate; 3, vacuolar P_i.

corresponding to a substantial rise in pH (Table 1). This suggests again that peaks 1 and 2 are due to ^{31}P in one compartment, peak 3 to ^{31}P in a different compartment. These results also indicate, as might be expected[1], that the cytoplasmic pH of these cells is regulated much more closely than that of the vacuole.

The pH values reported here should be regarded as approximate because the relationship between the δ values of ^{31}P compounds, and the pH as measured with a glass electrode, can differ in media of different composition. Although it has been reported[9] that Mg^{2+} has no effect on the titration curve of P_i, we find that both Mg^{2+} and concentrated protein shift the apparent pK_a of P_i and G-6-P to a lower value, by as much as 0.2–0.4 pH units. These effects will be described in detail elsewhere. The difference in apparent pH between the two compartments detectable by NMR in this tissue is, however, much larger than could be caused by known perturbations of the ^{31}P compounds. The ^{31}P method can therefore be useful for testing whether intracellular pH changes during certain physiological responses[1].

Canavanine potentiates the response of insect malpighian tubules to diuretic hormone and cyclic AMP

Ada Rafaeli & Shalom W. Applebaum

Department of Entomology, Faculty of Agriculture,
The Hebrew University, Rehovot, Israel

Insects regulate the amount of water they excrete via their malpighian tubules, the degree of stringency depending on the hydration of their diet and on the frequency at which they feed. The excretion of water is controlled by a diuretic hormone, which is released as required into the haemolymph by the corpora cardiaca[1,2]. Previous reports[3–5] have shown that non-protein amino acids, known to be neurotoxic in vertebrates[6] as well as in insects[7], lead to a disruption of water balance in insects. However, the exact mode of action of these amino acids has not been elucidated. We report here on preliminary experiments using isolated malpighian tubules of locusts (*Locusta migratoria migratorioides* (R & F)) which show that the non-protein amino acid L-canavanine inhibits fluid secretion *in vitro* by isolated tubules. Furthermore, when tubules, previously inhibited by canavanine, are subsequently stimulated by exogenous diuretic hormone (methanol extracts of storage lobes of corpora cardiaca[1,2]) or cyclic AMP (which mimics the action of diuretic hormone[1]), the stimulation obtained is much greater than that normally expected from diuretic hormone or cyclic AMP.

Table 1 The enhanced effect of cyclic AMP and diuretic hormone stimulation after L-canavanine treatment

Response to:	% Increase in rate of fluid secretion	
	s Control tubule	Canavanine-treated tubules
Cyclic AMP (10^{-3} M)	61.79 ± 5.90 (n = 13)	764.18 ± 45.81 (n = 11)
Diuretic hormone (5 pairs storage lobes)	88.83 ± 8.41 (n = 10)	339.99 ± 50.25 (n = 9)

Values are means ± s.e.m.

In contrast to mammals, insects do not possess a closed, high blood pressure circulatory system. Therefore they lack the initial force present in the mammalian kidney which is responsible for the formation of a primary urine filtrate. They rely primarily on a diuretic hormone for the production of a rapid flow of fluid through the tubules. The response to diuretic hormone is dramatic in blood-sucking insects that feed infrequently[8]. Between feedings they carefully guard their water loss but on feeding they imbibe vast quantities of fluid relative to their size, and the surplus water is then rapidly excreted. The *in vitro* response to exogeneous diuretic hormone or to exogenous cyclic AMP is far less striking in plant-feeding insects, such as locusts, that feed regularly. Presumably their malpighian tubules are already somewhat stimulated and the increase in secretion as a consequence of their exposure to diuretic hormone or to cyclic AMP, is limited. Most of the insect's body fluid is circulated through the excretory system in a short span of time[2] and derangement of the orderly process of events could rapidly lead to fatal dehydration[4,5]. This is what happens when L-canavanine[4] or other non-protein amino acids[5] are injected into the haemolymph of the insect. On the other hand when insects are exposed to chronic doses of L-canavanine by feeding[3] death is due to the retention of water. It is clear that such apparent contradictions need resolving.

Malpighian tubules of locusts were isolated according to the method reported previously[9]. This involved the removal of the whole length of the gut with the tubules attached. The gut was bathed by a physiological saline medium in a wax-bottomed Petri dish and the whole preparation was maintained under liquid paraffin. The tubules were cut at their entrance into the gut and the cut end was extended around fine glass rods held by the wax. Drops of secreted fluid thus formed at the cut end and were subsequently measured.

Tubules were incubated in bathing media until basal secretory rates stabilised. Bathing media were subsequently changed to those containing L-canavanine, at a concentration of 10^{-4} M and secretory rates were monitored. The results are shown in Fig. 1 and compared to the performance of the tubules in normal *in*

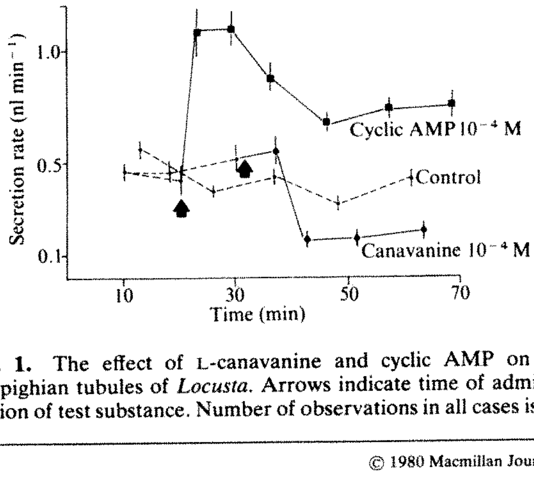

Fig. 1. The effect of L-canavanine and cyclic AMP on the malpighian tubules of *Locusta*. Arrows indicate time of administration of test substance. Number of observations in all cases is 10.

0028-0836/80/090872—02$01.00

vitro conditions and on addition of bathing media containing cyclic AMP. After 7 min of canavanine administration the rate of fluid secreted by the tubules drops by 72.7%. After this initial drop the fluid rate stabilises to a new basal level much lower than the normal original level. On the other hand, cyclic AMP stimulates fluid secretion almost immediately (3 min after administration) and the rate stabilises to a new basal level, higher than the normal original level. Inhibition is also evident when both cyclic AMP and canavanine are administered together in the bathing medium (Fig. 2). The cyclic AMP dose–response curve drops significantly when canavanine is present showing a substantial inhibition of tubular fluid secretion (32.6% inhibition at 10^{-3} M cyclic AMP).

In an attempt to determine whether canavanine inhibition is reversible, experiments were designed in which cyclic AMP was added to the bathing medium after treatment with canavanine. It was found that the tubules not only responded to the stimulatory effect of cyclic AMP but their response was enhanced to a remarkable extent (> 700% increase in rate) when compared to the normal response of untreated tubules (Table 1). Since cyclic AMP mimics the action of the naturally occurring diuretic hormone[1], we tested the response of the tubules to diuretic hormone in canavanine-treated and untreated tubules (Table 1).

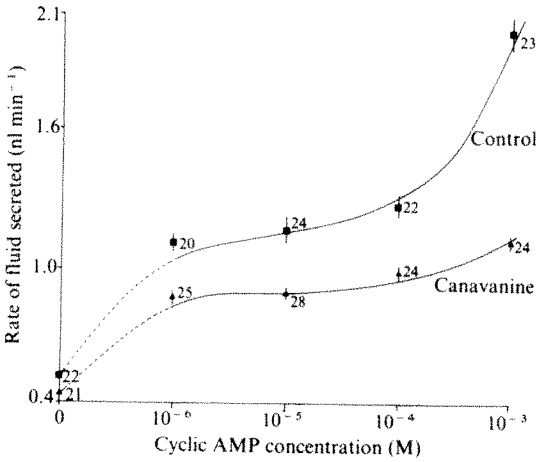

Fig. 2 The effect of L-canavanine on the normal dose-response curve of cyclic AMP. Subscript numbers indicate number of observations. Curves were fitted by eye.

It is clear that the diuretic hormone similarly stimulates canavanine-treated tubules to a greater extent (> 300% increase in rate) than untreated tubules. Thus canavanine, although in itself inhibitory, influences the tubules to react to a stimulatory compound much more effectively, possibly to the detriment of the insect.

We are now in a position to explain the apparent contradiction between the response of the whole organism to chronic exposure of canavanine (seen as a marked retention of water) and to a sequential exposure (seen as a loss of body fluid and dehydration). The inhibition of the isolated malpighian tubule by canavanine would lead to a marked retention of water. This is consistent with the retention of water which occurs *in vivo* in conditions of chronic exposure[3]. Since tubules themselves are capable of inactivating diuretic hormone[10], we assume that the inhibitor effect of canavanine occurs at a time when levels of endogenous diuretic hormone are much reduced. Canavanine apparently primes the tubules to respond to subsequent influx of diuretic hormone or to the generation of cyclic AMP. Indeed, the addition of diuretic hormone or cyclic AMP to tubules inhibited by canavanine elicits a dramatic increase in fluid transport, consistent with the dehydrated state attained *in vivo*[4,5]. This would only be true if exposure to canavanine is for a limited period which occurs when canavanine is administered by injection. Whether this priming is due to a general alteration in membrane transport properties is not yet clear.

We thank Professor G. A. Rosenthal for providing purified L-canavanine. A. R. thanks the Israel National Academy of Science and Humanities for support.

Use of cellulase antibodies to study leaf abscission

Roy Sexton

Department of Biology, Stirling University, Stirling, UK

Mary L. Durbin, Lowell N. Lewis & William W. Thomson

Department of Botany and Plant Sciences, University of California, Riverside, Riverside, California 92521

The primary leaves of the bean (*Phaseolus vulgaris* c.v. red kidney) are shed as the result of cell wall breakdown in the abscission zones found at the base of the lamina and at the stem–petiole junction. Horton and Osborne[1] suggested that cellulase (B 1 : 4 glucan 4-glucanohydrolase) was involved in this wall hydrolysis because its activity increased considerably during abscission. Although this result has been repeated on a wide range of plant material[2], critical scrutiny of the data has led several authors[3,4] to question the direct involvement of the enzyme in wall weakening. The following objections have been raised: (1) cellulase may be present at relatively high levels before abscission is induced[5], (2) although wall breakdown is confined to two or three layers of cells, cellulase is usually found over a wider area of the petiole, (3) the increase in cellulase which accompanies abscission may not take place until cell separation is essentially complete[3], (4) cellulase may increase without concomitant breakdown of the abscission layer[4]. One possible explanation for these anomalies is that these assays failed to distinguish between the various isozymes of cellulase, of which only one is postulated to be involved in abscission[6]. Recently, the specific isozyme thought to participate in bean leaf abscission (9.5 cellulase) has been purified and monospecific rabbit antibodies raised against it[7]. These antibodies do not cross-react with the other form(s) of cellulase and thus can be used both to quantify changes in 9.5 cellulase during abscission and to determine cytochemically the distribution of the enzyme. Using these antibodies, we have now made observations consistent with the participation of cellulase in the wall hydrolysis which leads to fracture.

Figure 1 shows a typical time course of abscission. At the time of induction the levels of total cellulase in the abscission zone can be easily detected. These increase dramatically after 18 h, when the force necessary to break the abscission zone declines. If the 9.5 isozyme is distinguished by radioimmune assay it is virtually undetectable in the uninduced tissue but starts to rise at 18 h just before a decrease in strength of the abscission zone. The correlation between the rise in 9.5 cellulase and the decrease in break strength is striking.

The antibody has also been used to localise the enzyme in formaldehyde-fixed cryostat sections (Fig. 2). This method reveals that 9.5 cellulase is confined to the two or three rows of

0028-0836/80/090873—02$01.00

cortical cells though which the fracture will pass and is also found in a wide band of vascular tissue. Unfortunately, nonspecific binding of antibody to the vascular tissue made interpretation of this observation difficult. To check these localisations, small fragments of tissue (100 μg) were dissected from the cortical and vascular areas of the fracture face and the cellulase content compared with adjacent areas outside the abscission zone. The stele contained very high levels of cellulase (2,012 units per g) in the zone compared with the vascular trace proximal to it (31 units per g). The abscission zone cortex also had elevated levels (167 units per g) compared with the general petiolar cortex (14 units per g). These viscometric assays are thus consistent with the immunocytochemical staining patterns showing 9.5 cellulase to be restricted to the fracture plane in the cortex. In the vascular tissue, cellulase is not limited to such a precise band of cells; this may account for the rather variable line of fracture in this tissue and objection (2) above.

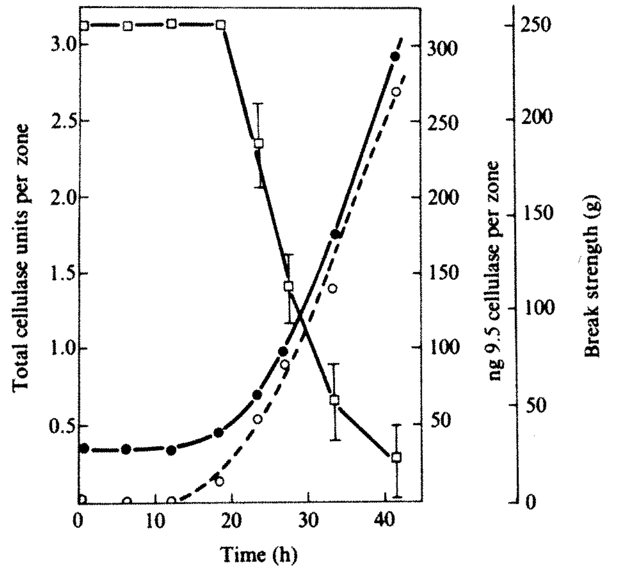

Fig. 1 A time course of abscission in the stem–petiole abscission zone of primary bean leaves. Eleven-day-old plants were induced to abscise by deblading 2.5 cm above the stem–petiole junction. The explants were placed in a chamber through which 50 p.p.m. ethylene was passed (1 l min^{-1}) in CO_2-free air. Samples of 70 zones were taken at the time points shown and the break-strength or force necessary to fracture the abscission zone determined[5] (□). Also, at each time point 70 zones were excised, extracted in salt-fortified buffer and total cellulase determined by a viscometric assay according to the methods of Lewis and Varner[5] (●). Radioimmune assay was carried out on the same samples (○). 9.5 Cellulase purified by the methods of Koehler *et al.*[7] was iodinated with ^{125}I using the chloramine T method essentially as described by Chard[8]. The iodinated cellulase was separated from its contaminants by chromatography on a cellulose column and elution by cellobiose[7]. The construction of a calibration curve and determination of unknown samples were carried out as described by Chard[8]. Results are all expressed on a per zone basis.

Thus, both the time course of 9.5 cellulase appearance and its distribution are completely consistent with an involvement in abscission. In an attempt to substantiate this role further, we injected serum containing 9.5 cellulase antibodies into the laminar abscission zone. It was hoped that the antibody would reach the exocellular cellulase producing the precipitin complex and so preventing its active involvement in wall hydrolysis. Two batches of 250 laminar abscission zones were injected with either 2 μl of normal rabbit serum or serum containing 9.5 cellulase antibodies (titre 4,900 units ml^{-1})[7]. This was achieved by passing the needle of a 'Hamilton' syringe along the centre of the petiolar pith cavity until the resistance of the pulvinus was met. At this point, the needle tip rests in the fracture plane in the vascular area where most cellulase is produced. Injections were made at 6-h intervals during the period when the 9.5 isozyme appeared, and then at 40 h the break strengths of the zones were determined. The zones injected with normal serum had an average break strength of 49 g (±26.1 g) whereas 90% of those treated with cellulase antiserum failed to break even if 200 g was applied. The 10% of this sample which did break in the abscission plane had mean break strengths of 167 g (±20.4 g). Thus, the injection of 9.5 cellulase antiserum had almost completely prevented wall breakdown. The levels of cellulase recovered from these cellulase antibody-treated zones was 24.4% of that in the normal serum controls. Presumably, this represents the enzyme which was inaccessible to the antibody, perhaps at intercellular sites in the tissue. As the antiserum has been proved to be specific to 9.5 cellulase[7], the fact that it stops abscission while the normal serum does not, confirms that cellulase has a central role in the abscission process.

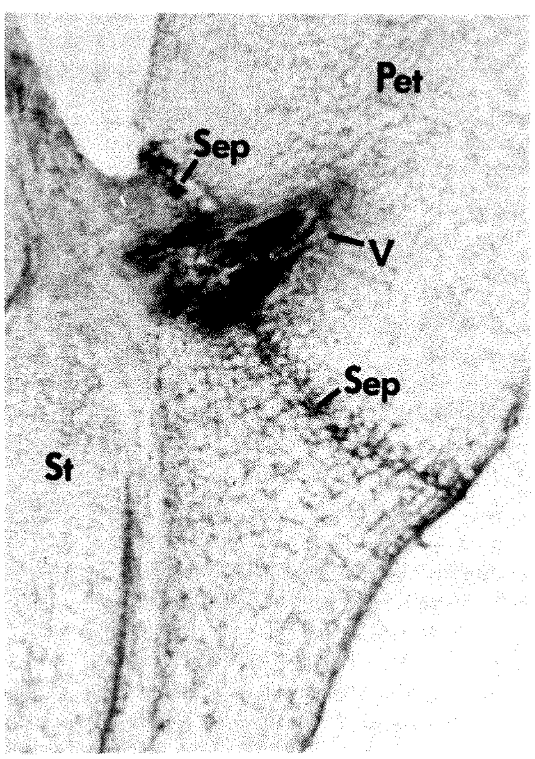

Fig. 2 A longitudinal cryostat section through the petiole base 36 h after the induction of abscission, incubated to show the distribution of cellulase. The enzyme was localised using the indirect method. Formaldehyde-fixed sections were placed first in rabbit anti-cellulase serum. After washing and denaturation of the native peroxidase[9], they were placed in diluted peroxidase-conjugated goat anti-rabbit immunoglobulin G. After further extensive washing, the bound peroxidase was localised by Graham and Karnovsky's method[10]. St, stem; Pet, petiole; Sep, separation layer; V, vascular trace. ×25.

STUDENT BOOKS SUPPLEMENT

The lives of the spineless

H.C. Bennet-Clark

Lecture Notes on Invertebrate Zoology. Second edition. By M.S. Laverack and J. Dando. Pp.194. (Blackwell Scientific: Oxford, 1979.) Paperback £5.50. *A Life of Invertebrates.* By W.D. Russell-Hunter. Pp.650. (Collier-Macmillan: West Drayton, UK, 1979.) £12.75. *The Invertebrates.* By R. McNeill Alexander. Pp.562. (Cambridge University Press: Cambridge and New York, 1979.) Hardback £28; paperback £7.95.

THE teaching of the zoology of invertebrates, like their classification, has been the subject of the changing fashion. Major pedagogic problems are whether to lay emphasis on systematics or on comparative functional biology, whether to underpin the subject with comparative anatomy or with arguments about phylogeny. The subject is so vast and has such an extensive literature that any attempt to present, in a single textbook, a comprehensive account of the invertebrates is bound to be unbalanced and incomplete; one must therefore judge any text on the insight it shows and on the impact it will have on students of all ranges of interest and ability. Here, at once, we have three very different approaches, none exhaustive but all with contrasting merits.

The easiest to evaluate, because its aims are the least controversial, is Laverack and Dando's *Lecture Notes on Invertebrate Zoology*, now in a somewhat enlarged and welcome second edition. As the title implies, the work offers a series of brief descriptions of all invertebrate phyla, giving a diagnosis and brief description of the anatomy, aspects of the physiology, development and classification of each phylum.

For small groups such as the Echiura or Brachiopoda, this formula works well enough, though the former are described within the chapter as both Echiurids and Echiurida; and for the latter there is neither a description of the structure and composition of their shells, nor of their embryology nor, possibly wisely, a discussion of their affinities.

With the larger phyla, notably the Protozoa, Arthropoda and Mollusca, the treatment becomes less successful. That of the Protozoa, compressed into 11 pages, is so brief as to be confusing, while for the Mollusca a similar compression leads to over-brief treatment of the major classes Gastropoda and Lamellibranchia (surely Bivalvia?). With the Arthropoda the problems seem more deeply rooted. I find it hard to equate the larval forms and metamorphoses of Crustacea with those of Insecta and so I am unhappy to see these described together. Whatever one's views of the controversy, one cannot reasonably ignore the work of S.M. Manton on Arthropod phylogeny; but there is no discussion either of this or of the relations between the major Arthropod taxa.

On the whole this is a useful book. The pictures are borrowed but plentiful and well chosen, there are brief but handy lists of references — with notable omissions of some major works published in the last couple of years; the layout is good and the price is right.

Russel-Hunter's *Biology of Lower* and *of Higher Invertebrates* are old friends and deserved the success they achieved. Published about ten years ago, they now creak a little so this, their derivative, *A Life of Invertebrates*, is timely. The formula is similar; a series of chapters on aspects of the biology of different phyla — a couple on the Coelenterates, a couple on Crustacea, eight on Mollusca, one into which "Walking Worms" (Ugh! — guess the phylum), the Tardigrada, Linguatulida and Echiuroidea (!) are concreted. Between and within these are useful chapters, sadly under-played in the other texts: on metamerism in the Annelida; on the super phyla of the animal kingdom; on the phylogeny of the invertebrates; and so on.

At points the layout and balance are slightly suspect. Protozoa are considered in a single brief chapter and after the Coelenterates, which receive three chapters. The insects are skimped in a single long chapter and in rather less detail than the treatment accorded to gastropod or cephalopod molluscs. Against this, the text is mostly well laid out, written and illustrated; and, above all, the author manages to convey an admirable feel for particular phyla without congesting his text with turgid and repetitive detail.

Even though it is so clearly presented, I have reservations about this book, even as the elementary text it is designed to be. I find many of the diagrams — such as those of the tunicates (32-2) or of the tardigrade (18-2) — too sketchy, though other original diagrams are excellent. I cannot but contrast the clarity of Russell-Hunter's exposition on worm locomotion with his excessively thin description of protozoan locomotion, a topic which Alexander handles lucidly and in detail. Above all, I find it hard to recommend to my students any text from which access to primary sources is so difficult. True, there is an annotated bibliography at the end of the book but exclusively to textbooks. It would, for example, be hard to discover details of the functioning of crustacean endocrine systems or of the lamellibranch filter-feeding gill from any of the sources he cites, even though both topics are described by him in considerable detail.

In Alexander's *The Invertebrates*, there is no attempt to describe the diversity of major morphological characteristics of invertebrate phyla and, in his preface, Alexander writes: "This sort of information is available in existing textbooks and indeed dominates some of them so that they fail to reflect current trends in zoology". Those who know and respect his other books will expect to be enlightened and excited by his latest offering — and will not be disappointed.

Here are many insights into the operation of invertebrates; I have only space to select a few titbits. The description of how a flagellum works, though simplified, is up-to-date, rigorous and understandable. It extends to a comparison of forms in which the direction of swimming is the same as that of the flagellar beat with those in which they are opposite. There is also a nice comparison of the roles of geodesic fibres in different phyla — in nemerteans as constraints on both the maximum and minimum length obtainable, in nematodes as antagonists to the longitudinal muscles, and in the mantles of cephalopods as constraints on the length during jet propulsion; the first two, of course, are well known but it is nice to see the story extended and elaborated. The shells of molluscs are treated both as geometrical structures and as examples of skeletal materials. Where, in these descriptions, a series of calculations is required to substantiate the argument, the reader is led through a gentle series of O' level sums!

As Alexander is scrupulous in referring to his sources in text, in figure legends and in generous chapter bibliographies, it is easy to pursue topics further. But woe betide the student who, buying this book, expects to master the invertebrates. He will not find much on the systematics or relations between invertebrate groups and only an occasional and often highly specific account of anatomical features. It must therefore, to achieve its aims, be used in conjunction with more solid conventional text books.

I find the book enthralling and irritating. Enthralling because of the insights that are offered and the novelty of the approach. Irritating because it treats the different invertebrate phyla in an inconsistent rather patchy way, because the student may be seduced into believing that comparative systematics and anatomy may be ignored and, rather pettily, because many aspects of invertebrate biology that I had laboriously collected to gild the unleavened gingerbread of my teaching are here gathered together, augmented, under one cover. As a text, it may not endure but it will certainly be influential and is a 'must' in any reading list.

These are three very different treatments. All offer a welcome relief from the larger 'straight' invertebrate zoology textbooks. None, alas, is sufficiently comprehensive to stand on its own. Equally, each has its considerable merits and a place in any course in invertebrate zoology. □

H.C. Bennet-Clark is Lecturer in Invertebrate Zoology at the University of Oxford, UK.

Parasitological literature

R.W. Ashford

Medical Parasitology. By R. Leventhal and R.F. Cheadle. Pp.168. (F.A. Davis: Philadelphia, 1979.) $19.95. *Parasites and Western Man.* Edited by R.J. Donaldson. Pp.220. (University Park Press: Baltimore, 1979.) £12.95. *The Biology of Parasitism.* By P.J. Whitfield. Pp.277. (Edward Arnold: London, 1979.) Paperback £7.95.

PARASITOLOGY may be approached as an applied or academic subject, and the applied subject requires workers at all levels of sophistication. These three books span the field: an elementary practical text; a more specialised applied text; and a strictly academic volume in which apology is made for dealing in detail with those applied aspects which have contributed to understanding.

The self-instructional text by Leventhal and Cheadle is aimed at students of laboratory technology, medicine and biology. This volume differs from many works by including short-answer self-assessments at the beginning of the book and at the end of each chapter, and a final examination at the end of the book. The text describes the main parasites of man, using verbal rather than graphic life cycle diagrams, tables, diagrams of the diagnostic stage, and glossaries of terms. A section deals with laboratory techniques. Finally there is a collection of colour photographs illustrating many of the parasites. Although the book was evidently produced hurriedly, as indicated by the many typographical errors, much of the information and terminology is out-dated. The colour photographs do not bear comparison with those in a number of readily available books; they are sometimes strangely coloured, and the inaccuracy of some of the mangification scales will make them of little help in identifying real parasites.

A concise text with test questions could have been a useful aid to revision for examinations; it is unfortunate that this volume fails to meet the required standard.

Parasites and Western Man, produced by a team of eminent contributors, is aimed at medical and veterinary workers at all levels, particularly those with public health interests. In materially advanced Western society much of the public health problem concerns imported infection, but there are also surprisingly large numbers of parasites which hang on, and even thrive, in Western countries. In his introductory chapter, Nelson, provocative as ever, expounds the argument that parasites may have a positive role in human health, and that the search for a balanced relationship with them may be more valuable than blind destruction.

Each major group of parasites is covered in a chapter, and the ubiquitous head lice are given one of their own. Concluding chapters deal with the role of pets and domestic animals in human parasitic infections. The life cycles, modes of transmission, clinical and public health aspects, and statistics of occurrence of parasites in Western countries are outlined; and in the case of the more prevalent lice and mites, considerable epidemiological detail is given. More of this detail would have been useful for other parasites.

If this work has a wide enough circulation, it may help to control both the irrational horror which attends the discovery of a louse or pin-worm, and the equanimity with which the pollution of our residential areas by faeces from pet animals is commonly viewed. Despite a few slips, and the repetition inevitable in a multi-author work, this is a highly readable, thoroughly authoritative text which fills a gap in the literature.

Whitfield's *Biology of Parasitism* is a brave effort to summarise, for undergraduate and early postgraduate biologists, the outcome of technological and conceptual advances in the subject over the last ten years. The treatment of the whole subject of "Association Biology" in a "unified" language has allowed a broader view than is customary. Structure, nutrition, physiology, behaviour and ecology are reviewed in separate chapters.

The impressive breadth of subject covered has meant that depth has been limited; instead of indulging in broad generalisations, however, the author has achieved this by concentrating in depth on a few well-worked examples. In many cases a single association is viewed from different aspects in different chapters, and this gives continuity to a work which could easily have become disjointed. Recent information on surface interactions between parasites and hosts is covered in detail, and though the whole subject of parasite immunology is reduced to thirteen pages, the latest advances are summarised without gross oversimplification. The section on population studies is notable for the contribution which the author and his colleagues have made, but there remains an important communication gap between applied epidemiologists and the theoretical ecologists.

There is no attempt to be comprehensive or to supersede existing textbooks; this is a complementary work for advanced students. It will be particularly valuable as a basis for seminar discussions and as a source of wide-ranging up-to-date references. My only complaint is that the fashionable complexity of the language used, though meticulously accurate, will preclude the use of this book by many overseas students.

Three contributions to the sagging shelves of parasitological literature: our students, on appropriate courses, will be advised to avoid Leventhal and Cheadle, to at least read Donaldson, and to buy Whitfield. □

Radioactivity in context

Malcolm C. Scott

Radioactivity: A Science in Its Historical and Social Context. By E.N. Jenkins. Second edition. Pp.197. (Taylor and Francis: Basingstoke, UK, 1979.) Paperback £4.75.

THE discovery of radioactivity and, subsequently, fission is one of the many fascinating stories associated with the development of science generally, and one which gives as valuable an insight as any into the nature of the scientific method. The general topic of radioactivity and its exploitation is also one for which it can be argued that there are moral issues involved, principally in the use of nuclear power. A book covering both these aspects should, therefore, provide stimulating reading.

It is therefore with regret that one records that the author of this book has not been able to meet the challenges presented in communicating either the excitement of discovery or the moral implications. Although the thirteen chapters cover a reasonably comprehensive spread of material, ranging from 'The Discovery of Radioactivity'' through "The Chemistry of the Fission Products" to "The Biological Effects of Radiation", the quality of the coverage is not very uniform. As the author was a research chemist until taking holy orders in 1962 it is perhaps to be expected that the chemistry sections are the most fluent. However, some of the other sections seem disjointed and even faintly dated, in the sense that developments since the book's first edition, in 1962, sometimes do not get the weight which workers active in the field would assign to them. Additionally, the advances made in the teaching and textbook presentation of scientific material in the 1960s and 70s are not reflected here: in fact, parts of the book are distinctly heavy going, and would hardly seem to appeal to the first-year university student, or equivalent, for whom the book is intended.

There are a number of minor errors and misleading statements which, though not central to understanding, leave one uneasy. For example, the different quenching mechanisms in a Geiger counter are confused (page 24) and the definition of neutron multiplication factor (page 107) cannot easily be related to and is inconsistent with the data given in the associated table. Perhaps the most disappointing aspect, however, is that moral and social questions do not get the depth of coverage which one would expect from reading the introduction. For example, what does the risks versus benefit balance sheet look like for the medical uses of radiation or for nuclear power? Are enough facts known for us to be able to draw up such a balance sheet? Can there be a qualitative difference between risks producing the same number of deaths in a given period of time and, related to this, what makes some risks socially acceptable whilst other, lower ones, are unacceptable? The reader looking for a discussion of these and related questions will not find them, yet these, surely, lie at the heart of any 'moral' evaluation.

Given the didactic philosophy behind the *Wykeham Science Series* and the excellence of some of the resulting books this one is somewhat disappointing. □

Malcolm C. Scott is a Senior Lecturer in the Department of Physics at the University of Birmingham, UK, in charge of the MSc course on the Physics and Technology of Nuclear Reactors.

Behaviour of practical systems

I.S. Grant

Transmission and Propagation of Electromagnetic Waves. By K.F. Sander and G.A.L. Reed. Pp.410. (Cambridge University Press: Cambridge and New York, 1978.) Hardback £24.50; paperback £5.95.

THIS book is intended to be used as a textbook in the later stages of undergraduate electrical engineering or applied physics courses. The emphasis is on the practical design and inherent limitations of the transmission lines, waveguides and antenna systems used in modern communications.

Familiarity with Maxwell's equations is assumed, and the book starts by deriving the plane wave solutions to Maxwell's equations. Boundary conditions are discussed, and reflection, refraction and absorption at interfaces between media are described with considerable mathematical elaboration. Guided waves in transmission lines and wave guides, and waves radiated from antenna, are all introduced as solutions to Maxwell's equations. I have some reservation about whether this approach is the most suitable for all students whose primary aim is to understand the behaviour of practical systems. But the treatment is not very formal, and the authors illustrate their argument with realistic worked examples. The first half of the book is completed with a standard treatment of transmission line theory, discussing reflections and impedance matching, and with a short section on the reflection of pulses.

The second half of the book is devoted to the propagation of communication signals in transmission line, waveguide and microwave systems. Attenuation and noise are considered for all the systems, and the characteristics of cables and waveguides capable of carrying signals over very long distances are described in considerable detail. The generation, reception and processing of signals is not discussed except where it is necessary as part of the explanation of how signals may be changed during propagation; modulation and multiplexing have to be understood, for example, in order to consider the signal degradation due to intermodulation when non-linearities occur in repeater amplifiers. The treatment of propagation is excellent — not difficult, but clearly explaining what is happening in terms of the basic principles given in the earlier part of the book. □

General geophysics

D.H. Tarling

The Physical Environment. By B.K. Ridley. Pp.236. (Wiley: New York and Chichester, UK, 1979.) £8.50.
Palaeomagnetism and Plate Tectonics. By M.W. McElhinny. Pp.357. (Cambridge University Press: Cambridge and New York, 1979.) £7.50.

RIDLEY'S is an interesting little book designed to provide an awareness of the total underlying physical structure of the environment for students of science and engineering. The scientists to whom the book is addressed include social scientists and it therefore uses a minimum of mathematics in its attempt to provide a unified basis for the comprehension of the relationships between astronomy, geology, meteorology and oceanography. The object is therefore laudible but possibly unattainable within such a small compass unless more rigorous mathematical treatment were introduced. This would then probably lose the innumerate section of his audience, exactly those people most likely to benefit from such a synthesis.

The contents are logically organised, starting in outer space and time, before considering the internal and then external features of the Earth. Halfway through there is a more general discussion of the forces of nature, including nuclear reactions, electromagnetic, chemical and gravitational forces, and then a return to the Earth's surface and the forces operating in and on the oceans. The book then begins a return to the outer limits of the Universe, discussing the Earth's atmosphere, solar and stellar processes and finally considers the origin of the Universe, the Solar System and life.

The tour is thus certainly comprehensive and there is little that can be considered either wrong or over-simplified to the extent of giving misleading impressions. It is thus difficult to pin down a feeling of uneasiness. Some of this almost certainly stems from the style, which is generally very readable but tends to launch into purple prose during either introductory or linking sections. Another reason for unease may be the balance given to different aspects. Four pages on Obler's paradox (and extra reference later on) seems excessively unnecessary when inertial waves are not discussed (only inertial oscillations) yet are virtually assumed within the consideration of wind patterns. Other unease arises from inadequate checking. For example, the age of the base of the Cambrian has different values on different pages. Such errors are trivial in terms of the context, but indicate a lack of care in proof-reading. Another unease is the occasional error — the magnetic dipole is "inclined" at 11° relative to the Earth's axis of rotation, but this state is to be known as declination.

A final cause for unease is the apparent reliance on the London Geological Museum for many of the geological-geophysical 'facts' and diagrams. While the Museum's exhibition is an excellent one, it is already out of date in some aspects, such as the presence of a basaltic layer beneath the continental granites — a feature that appears in almost all of the diagrams. It is similarly misleading, or indeed incorrect, to say that volcanic activity at subduction zones is due to the melting of light material thrust into the asthenosphere.

In general, the colour diagrams are excellent — mostly derived from the Geological Museum and NASA — but the black-and-white photographs are poorly reproduced, originally colour prints have poor contrast in grey tones, and it seems unnecessary to actually print the *Times* weather map with lettering from the reverse side still showing. The omission of the fold-out weather satellite photographs could have released money for improving other photographs. However, the diagrams are mostly clear and well produced, as is the book as a whole. There are problems at the end (with answers) for those who wish to test themselves; and there is further reading provided for each chapter, although I see no reason that the reading for chapter 5 is incorporated with that for chapter 4 and there is none for chapter 7.

Despite the qualms, it is possible to recommend the book for the general student scientist, although it is clearly designed for a British rather than a world-wide market. One hope is that this may be a short print; a revised edition would be likely to be more strongly recommended.

The second book, McElhinny's *Palaeomagnetism and Plate Tectonics*, is an entirely different proposition. This is aimed at a specific market, the (advanced) undergraduate geologist or geophysicist in particular. When it was originally issued in 1973, this was an excellent introduction to palaeomagnetism and a review of extant palaeomagnetic data. This "first paperback edition" is, in fact, a straight reprint of the hardback edition. Such a term implies to me that some editing or updating has been undertaken and as this is certainly not the case, the publisher's claim that it is "a review of the state of knowledge in the subject", which was justified in 1973, cannot conceivably be justified in 1979. The data base has expanded severalfold since McElhinny submitted the manuscript in, presumably, 1972. There have also been major advances in our understanding of magnetic processes within rocks, the behaviour of magnetic minerals, the instrumentation to measure either the magnetisation or other magnetic properties, and so forth. It is thus invidious to both the author and the reviewer to comment in detail on how certain aspects no longer correspond with current knowledge or awareness. CUP would have been better advised to issue a revised edition. As it is, this book can still be recommended as highly readable and well presented. The production is good and reasonably durable. It is with sorrow and disappointment that one can no longer give this paperback edition the recommendation which the original hardback deserved so well. □

D.H. Tarling is Senior Lecturer in Geophysics at the University of Newcastle-upon-Tyne, UK.

Solid state physics

W. Cochran

The Solid State. By H.M. Rosenberg. Second edition. Pp.274. (Clarendon Oxford University Press: Oxford, 1979.) Hardback £5.50; paperback £2.25.

THE first edition of this book appeared in 1975 and I feel sure that it was read and enjoyed by most lecturers in solid-state physics, and that they will have recommended it to their students. It is one of the Oxford Physics Series, which the Editor describes as core texts intended to cover material usually treated in the first year of honours courses in English universities, or in the second year in Scotland. The Editor introduces the book as one which succeeds in capturing the spirit of the stimulating lecture course that Oxford undergraduates have enjoyed for many years from Dr Rosenberg, and goes on to claim that it requires only a fairly basic background in mechanics, electricity and magnetism, and atomic physics, along with relatively intuitive ideas in quantum physics.

The only important difference between the second and first editions is the addition of a fourteenth chapter, on superconductivity. While I liked this chapter as well as any, I fear it will be beyond the scope of students — particularly of materials science and engineering — at the level for which the book is intended. One or two new problems have been added after the earlier chapters, and fourteen after the final one, to give a total of about 120. Numerical answers are now given where appropriate, although the author admits that he views the ensuing correspondence with some trepidation. A new section has been added at the end of chapter 11, to explain the phenomenon of saturation in NMR and ESR. Otherwise the second edition stays very close to the first. The opportunity has been taken to remove some minor errors: in particular Fig. 8.6 no longer conveys the impression that band overlap occurs at the zone boundary in one dimension. A remaining source of possible confusion is that while page 124 has "we shall use e for the modulus of the electronic charge . . . . .", in the section preceding a discussion of the Hall effect we read ". . . . where e is the electronic charge".

How does Rosenberg's book compare with the dozen or so others which a lecturer might recommend? The author's own list of 'standard texts', with his comments, is as follows:

Solid State Physics. By N.W. Ashcroft and N.D. Mermin. (Holt, Rinehart and Winston: New York, 1976.) A detailed, higher-level, modern treatment.

Solid State Physics. By J.S. Blakemore. (Saunders: Philadelphia, 1974.) A lively intelligent presentation.

Solid State Physics. By A.J. Dekker. (Macmillan: London, 1960.) A good introductory text.

Introduction to Solid State Physics. By C. Kittel. (Wiley: New York and Chichester, UK, 1976.) A standard text, brim-full with information and data.

Elementary Solid State Physics. By M.A. Omar. (Addison-Wesley: Reading, Massachusetts, 1975.) An introductory text which includes some unusual topics.

Physics of Solids. By C.A. Wert and R.M. Thomson. (McGraw-Hill: New York, 1970.) This is at a lower level than the other texts. It is very well written and illustrated.

Personally I would immediately delete Omar's book from any such list, as it includes a truly astonishing number of errors and misconceptions in its first few chapters, and I would add

Solid State Physics and Its Applications. By R.J. Elliott and A.F. Gibson. (Macmillan; London, 1974.)

Physics students in Edinburgh first meet solid-state physics in an introductory review course of 15 lectures given in the second year. The recommended text book is currently:

Real Solids and Radiation. By A.E. Hughes and D. Pooley. (Wykeham: London, 1975.)

A further thirty or so lectures are spread over the third and fourth years of the honours course. When I gave the third year course I recommended Rosenberg and Kittel, in that order, and in the fourth year I reversed the order. So to give the publishers a publishable quote — A book which we shall certainly continue to recommend to students in Edinburgh. □

W. Cochran is Professor of Natural Philosophy at the University of Edinburgh, UK.

Animal behaviour in laboratory settings

Trevor W. Robbins

The Experimental Analysis of Behaviour. By E. Fantino and C. Logan. Pp.559. (Freeman: Reading, 1979.) £8.40. *Stimulus Control of Behavior.* By H.K. Rodewald. Pp.162. (MTP Press: Lancaster; University Park Press: Baltimore, 1979.) £6.25.

FANTINO and Logan have undertaken the timely but formidable task of writing a student text which attempts to reconcile two often-opposed schools of thought in the study of behaviour: the formulation of general principles from laboratory experiments versus the ethological emphasis upon species-specific behavioural patterns, adaptation to ecological niche and evolution. Generally, they succeed admirably in this well produced and reasonably priced work which takes as its theme the dual ontogenetic and phylogenetic determinants of behaviour.

After a brief historical review of learning theory, basic concepts of operant and Pavlovian conditioning, as well as of "non-associative" learning such as habituation are described. Chapters on stimulus control, conditioned reinforcement, choice and aversive control then follow, but the rather staid headings belie the fascination of the topics subsumed. These include behavioural contrast, attention, concept formation, behavioural chains, self-control, punishment, self-punitive behaviour and "learned helplessness". There are also welcome allusions to the more successful applications of behaviour therapy such as the "token economy".

From these laboratory concoctions we are delivered quite smoothly across the 'Great Divide' to consider the niceties of courtship in snails and other behaviour in the wild. The ethological section is in many ways symmetric with the previous one, with chapters on species-specific behavioural patterns, "the natural history of learning" and two lengthy surveys of learning in invertebrates. The authors manage to cover taste aversion, specific hungers, imprinting, pigeon-homing, song-learning and the controversies surrounding the famous bee-dance. Considering such breadth, inevitably there are neglected areas. Thus, there is little on motivation, where one might perhaps have expected something on feedback control theory. Similarly, memory and claims of language-learning in animals are barely mentioned. I should have preferred rather less on learning in Protozoa to Platyhelminthes, where so much of the evidence is indecisive. On the other hand, important advances in the neurophysiology and analysis of learning in *Aplysia* are well represented.

The book is best suited for advanced students, as few punches are pulled when discussing theoretical issues. For example, the ramifications of Herrnstein's Matching Law are given an extensive quantitative treatment (though Rescorla-Wagner Theory is conveyed with not one equation!). The authors' boldness in incorporating the most recent material into their argument is also impressive, although the drive to synthesis sometimes obscures dissemination. For example, the critique of the use of 'anxiety' as an intervening variable to explain conditioned suppression seems mis-directed when couched physiologically. Neither was I convinced that satiety is "most likely" not a learning phenomenon (page 42), nor by the somewhat glib explanations of "vicious-circle" behaviour.

Minor blemishes are the typographical error which makes nonsense of Equation 7 page 241, and frustrating references to unpublished talks at meetings, sometimes by one of the authors (for example, page 283)!

However, the book is at its best in the concluding integrative section when the obvious merits of applying 'laboratory' techniques to ethological problems are made clear with examples taken from optimal foraging and displacement or adjunctive behaviour. Finally, the authors examine the "challenge to reinforcement theory". The challenge, with this book, seems well met.

Rodewald's book *Stimulus Control of Behavior* provides a striking contrast. Here is an unambitious tome which really does justify its perhaps puzzling description as a textbook for undergraduates or a "reference handbook for professionals who will find here a source of useful technology for the study of animal behaviour in laboratory settings". The subject-matter is probably of limited appeal, but is developed in easy steps in the classical pedagogical manner. The book is perhaps most suitable for advanced tuition in practical classes of operant conditioning involving experiments in psychophysics, attention, discrimination or memory. In his book, Rodewald cites some 159 references whereas the corresponding chapter of Fantino and Logan uses 133. It is perhaps of interest that these totals share only 14 references in common. Does compromise between schools of behaviour jeopardise concordance within them? □

Trevor W. Robbins is a Lecturer in Experimental Psychology at the University of Cambridge, UK.

Developmental psychology

James Russell

Human Development. By T.G.R. Bower. Pp.473. (Freeman: San Francisco and Reading, 1979.) $15; £8.40. *The Functions of Language and Cognition.* Edited by G.J. Whitehurst and B.J. Zimmerman. Pp.313. (Academic: New York and London, 1979.) $21; £13.65.

THE impression gained from reading these books in succession is that the aim of the Bower book is to review in order to teach and that of the Whitehurst and Zimmerman volume to review in order to present the case for modern functionalism. This is not to imply that Bower's book lacks a consistent theoretical standpoint; rather that the differentiation model which he espouses here, as in his other books, is such a broad one that there is much scope for eclecticism. Thinkers as different as Leibniz, Herbert Spencer, Piaget and, of course, Heinz Werner have presented differentiation models of development, and in Bower's case the framework allows him to support such diverse positions as neo-Piagetianism, social learning theory, and Laingian theory. There is much to agree with in his treatment of the standard developmental topics, but I think that his statement of the differentiation position as implying that concepts develop from the abstract to the concrete is needlessly paradoxical.

One of Bower's main neo-Piagetian themes is the notion that concepts and skills develop by being replicated on progressively higher levels. Given this, it is difficult to resist the facetious comment that Bower's own writings appear as points on a similar spiral: ideas explored in the early 1970s have now been presented a number of times each with slightly wider degrees of generality and very slightly wider data bases. It is a pleasure to encounter some of Bower's adventurous theorising at his current level (for example, the INRC group being first expressed in infant action) but less than a pleasure to find oneself noting how little of the referenced work has ever or will ever appear in journal form. Bower also evokes the same prissy reflexes by his too brisk treatment of certain topics: the evidence for the genetic basis of schizophrenia, personal construct theory are two such. But in general this book will make an excellent initial text for developmental courses so long as the course leader is at least as healthily sceptical as Bower himself.

Anyone who is at all familiar with the contents of the past three or four years of American developmental journals will feel at home in the Whitehurst and Zimmerman volume. The strength of the book lies in the fact that — as the editors point out — the writers were actively encouraged to make their contributions cohere. They succeed in the attempt, but given that most youngish American developmental psychologists have already been channelled towards a very definite stylistic and theoretical consensus I doubt if they had to try very hard. This is not meant negatively: the contribution of 'cognitive social learning theory' taken as a whole has been considerable even if the results of individual studies are seldom breathtaking.

Piagetian theory provided the impetus for much of the work reviewed here, but the Pragmatist tradition and experimental methodologies determined its orientation. Most of the contributors repudiate structuralism in cognitive (Piaget), linguistic (Chomsky), moral (Kohlberg) and memory (multistore models) development and most rely on the efficacy of social modelling, concept teaching and verbal rule learning in their arguments. There are many good things to be found: Ornstein provides an excellent comparative review of adult and child experimental work on memory and tries to show where cross fertilisation is and is not possible; Liebert directs a well aimed dart at the Kohlberg bubble; and Rosenthal forges some links between laboratory data and social and clinical problems. Overall this book will prove a useful text for advanced students and researchers who will find the rigorous referencing particularly useful. My only real misgiving is that the 'cognitive' in 'cognitive social learning theory' is being done less than justice here, as elsewhere. Why, after all, do modelling and training work? □

James Russell is Lecturer in Developmental Psychology at the University of Liverpool, UK.

Personality assessment

Graham F. Wagstaff

Personality. By R. Forgus and B. Shulman. Pp.434. (Prentice-Hall International: Hemel Hempstead, UK, 1979.) £11. *Personal Enquiry and Application.* By M. Sherman. Pp.546. (Pergamon: Oxford and New York, 1979.) £7.95.

I AM sure that anyone involved with the study of personality will find these books valuable reading. Contrary to the approach adopted by a number of recent textbooks in the area, these volumes do not attempt to give an overview of a vast number of theoretical approaches, but attempt to view the subject matter from more specific perspectives. The authors recognise that the area of personality is confusingly diffuse and it is particularly difficult to select material, other than that concerned with descriptions of major theoretical approaches, that does not seem to give a superficial coverage of virtually all areas of psychology.

In the first two sections of his book Sherman provides a very useful and easily read critical presentation of methodology in the study of psychology, including the basic concepts of experimental design and analysis, correlation research, ethics of research, reliability and validity, and a review of interviewing, questionnaire, projective and behavioural techniques of assessment. In the final section he presents a critical discussion of psychoanalytic and cognitive learning approaches to personality, spending a considerable amount of space on the behaviourism/situationism issue. However, due to this latter emphasis detailed description of individual personality theories is very restricted, and those readers with a more phenomenological bias or who have interests in factor analytic trait theories, may feel that much of the extensive discussion of the principles of behaviourism is unnecessary and gives an unbalanced view of the issues in personality which is not specified in the title of the book.

Ironically, although Forgus and Shulman specify that their approach is a cognitive one, the reader may find that the content is more representative of the general area of personality than that covered by Sherman. The initial discussion seems to be more pertinent to the area of personality and includes guiding postulates for personality theory, and definitions and constructs used in personality theory. This is followed by critical overviews of a variety of personality theories including Freud, Erikson, Murray, Rogers and Lewin. It is not until chapters 5 and 6 that the cognitive orientation is clearly emphasised, and just as Sherman indulges in a description of behaviouristic principles, Forgus and Shulman engage in a discussion of the relationships of the perceptual system to need-related stimuli. In this way they attempt to construe personality within the context of motivation and the way events are perceived. Consequently they reinstate the concept of motivation as a primary concept in the study of personality. This analysis is then applied to personality development, interpersonal behaviour and psychopathology. Although Forgus and

Shulman's analysis is extremely well formulated, the breadth of the subject matter may still leave the reader very unsure as to the boundaries of the area, and for further reading he may decide that he had better read up all areas of psychology.

In spite of the wide content area, the factor analytic approaches to personality are again conspicuously absent. I find the absence of discussion of the theories of Cattell and Eysenck in both books rather puzzling in view of the pertinence of these approaches to issues involving the nomothetic trait and type concepts of personality, the extensive experimental work that has been conducted in relation to them and the ubiquitous presence of studies using the 16PF and the EPI. I would have thought Eysenck's behaviouristic analysis would have been particularly appropriate to Sherman's discussion of the behaviourism/situationism issue.

Both books assume little previous psychological knowledge of the reader and are easily comprehended. However, I feel that they will be of most value as supplementary, rather than main texts in personality. In this role both are sufficiently individualistic to assume equal prominence. □

Graham F. Wagstaff is Lecturer in Personality and Social Psychology at the University of Liverpool, UK.

Surveying microbiology

D.G. Smith

Biology of Microorganisms. By T.D. Brock. Third edition. Pp.802. (Prentice-Hall International: Englewood Cliffs, New Jersey and Hemel Hempstead, UK, 1979.) Hardback £17.15. *The Life of Yeasts.* By H.J. Phaff, M.W. Miller and E.M. Mrak. Second edition. Pp.341. (Harvard University Press: Cambridge, Massachusetts and London, 1979.) £10.50.

In these days of multi-authorship of textbooks, it is becoming increasingly rare for a major textbook to have a single author. T.D. Brock's production of three editions of *Biology of Microorganisms* within a decade must therefore be acknowledged as a remarkable achievement and it confers the advantage of a uniformity of style throughout the work.

The third edition follows the general format of earlier editions: the pages are large and attractively laid out although often wasteful of space. The subject coverage remains comprehensive and has been extensively updated to cover recent developments in areas such as recombinant DNA and bioenergetics.

A welcome addition to this edition is the incorporation of what the author calls "vignettes" on historical aspects of microbiology. These occur throughout the text labelled "a bit of history". Although these sections can easily be skipped, an appreciation by students of the historical development of a piece of knowledge is certainly to be encouraged.

Another feature of the new edition is the inclusion of five appendices (42 pages) containing detailed information on energy calculations, mathematics of growth, biochemical pathways, bacterial classification and microscopy.

This book is one of only two or three available titles which can be recommended as the main textbook purchase by undergraduate students of microbiology.

Now, where would we be without yeasts? For millennia they have been in the service of man making alcoholic beverages and raising bread. They are as domesticated as the cow: no other microorganism is as well known or as widely used.

The second edition of *The Life of Yeasts* is an authoritative but highly readable account of most aspects of the properties and usefulness of the yeasts. The authors set the scene with a brief historical chapter which also introduces us to the fact that yeasts are a heterogeneous collection of fungi from the *Ascomycotina, Basidiomycotina* and the *Deuteromycotina*; the unifying features being absence of asexual spores (conidia) and the ability to live as single cells. Six chapters deal mainly with the cell biology of yeasts and three with their ecology and practical applications. Included in the latter is a description of recent developments in the utilisation of yeast cells as food (single cell protein). Yeasts grown on hydrocarbons or carbohydrates are already being fed to animals and there can be little doubt that this will become increasingly important. Another aspect of mounting significance is the spread of pathogenic yeasts freed from bacterial competition by the extensive use of antibiotics.

This book is suitable for the non-specialist at school or college but there is also an appendix containing reference material on classification and characteristics of yeast genera which will be useful to the specialist. □

D.G. Smith is Senior Lecturer in Microbiology in the Department of Botany and Microbiology, University College London, UK.

Field and Laboratory Exercises in Ecology

S.D. Wratten and G.L.A. Fry

This book represents the first practical integration of quantitative exercises in plant and animal ecology. Fifty-six exercises, grouped in pairs of complementary field and laboratory experiments and arranged round five major ecological themes, and worked through in full detail and a further 150 variations, some suitable for long term projects, are offered.

Paper £7.50

New titles in the 'Studies in Biology' series:

115 Vocal Communication in Birds

Clive K. Catchpole

The underlying theme of the book is not only to show how birds communicate with their vocalizations, but also to discover what information is being passed and why. In spite of recent advances, the central problem of why birds have evolved such complex and varied vocalizations remains one of the most interesting, challenging and elusive questions in biology.

Paper £2.40

116 Influences on Animal Growth and Development

Roy A.L. Batt

This book, the first of its kind, is an introduction, not so much to the processes of growth and development, but to the *influences* on these processes. It will be of use and interest both to the biologist and to the agriculturist.

Paper £2.20 approx
Publication March

117 Collagen: The Anatomy of a Protein

John Woodhead-Galloway

Collagen is one of the best characterized proteins. Dr Woodhead-Galloway shows how from the knowledge of its primary molecular structure, one can logically build models of microfibril and fibril properties that produce an accurate picture of the protein's function in living tissues.

Paper £2.20 approx
Publication April

118 Social Behaviour of Animals

John M. Deag

'Social behaviour' is behaviour involving two or more animals of the same species. This comprehensive and up to date book introduces the reader to the very topical subject of social behaviour and its adaptive significance.

Electromagnetic quintet

D.S. Betts

Electromagnetics. By S. Seely and A.D. Poularikas. Pp.790. (Marcel Dekker: New York and Basel, 1979.) £14.40. *Electromagnetic Fields.* By A.M. Portis. Pp.775. (Wiley: Chichester, UK, 1979.) £16.30. *Electromagnetic Fields.* By R.K. Wangsness. Pp.576. (Wiley: Chichester, UK, and New York, 1979.) £10.75; $20.95.*Electromagnetism: Principles and Applications.* By P. Lorrain and D.R. Corson. Pp.507. (Freeman: Reading, 1979.) Paperback £7.30. *Electricity.* By C.A. Coulson and T.J.M. Boyd. Second Edition. Pp.392. (Longman: Harlow, UK, 1979.) £6.95.

THE first of this quintet is a big book, physically big and big in ambitions, intended for science and engineering students approaching graduation. Seely and Poularikas have set themselves the worthwhile task of developing electromagnetic theory and then applying it within an unusually broad context. This had led to the inclusion of "certain details of acoustics, thermal fields, plasmas, elasticity, physical and geometrical optics". So far so good. The trouble is that these details are rather too often given undue prominence. For example, Chapter 13, "Resonance, Resonators and Coherence", contains four sides of largely mathematical text devoted to the mechanical vibrations of strings and membranes. And in Chapter 8 on wave phenomena the reader finds himself wading through eight sides devoted to longitudinal waves, including a more complete proof of the velocity of sound in gases than is to be found in many basic texts on waves. I feel that in this respect the authors should have exerted a little more self-discipline.

On the other hand there are some very good things. Chapter 7, "Interactions of Charged Particles with Electric and Magnetic Fields", is extremely good, leading naturally into plasmas and the design of fusion reactors. And Chapter 12, "Elements of Diffraction Theory", gives thorough coverage to a tricky topic; and I also like much of the treatment of waves in unbounded media (not mediums, please!) and guided waves.

Circle No. 31 on Reader Enquiry Card.

The development of the basic equations and ideas of electromagnetism is fairly heavily loaded with references to non-electromagnetic phenomena and this seems to work reasonably well. Three minor quibbles: (1) On pages 236 and 367, it is surely wrong to regard $\underline{\nabla}\times(\underline{\nabla}\times\underline{X}) = \underline{\nabla}(\underline{\nabla}\cdot\underline{X}) - \nabla^2\underline{X}$ as a vector identity (except in Cartesian coordinates) — it is a definition of $\nabla^2\underline{X}$. (2) The satisfying proof given that current loops experience dipole-like torques in applied fields does not depend on the loop being plane, so it was a pity to preface the proof by the statement that $\underline{m} = I\underline{S}$. (3) It is doing Maxwell's equations an unjustice to describe (page 363) the charge continuity equation as auxiliary to them — it is built in.

In short, this is a valuable but somehow unwieldy book. It is not helped by its appearance with its typewriter print and spidery diagrams.

In Portis' *Electromagnetic Fields,* again there is à stated aim of putting a considerable amount of applied physical material in with the basic electromagnetic theory. Portis argues that this is more necessary than it was ten years ago because of the decline in the fraction of physics majors (in America) going on to graduate school. It is an argument whose application to the British scene is less than clear. Anyway, the result is a most attractive textbook but one which is fairly expensive and rather too wide-ranging to make large sales in the UK. "The selection of topics has been made within the context of a serious attempt to develop the classical theory of electromagnetic fields from a contemporary point of view." Some of these topics are flagged as being more advanced or specialised (for example, helicons, magnetic dichroism, Aharonov-Bohm effect) and the pages beyond 600 are given over to (valuable) appendices. So the 'core' of the book is in fact of quite manageable proportions, with each of the 15 chapters having a summary and generous number of both exercises and problems. It is well produced with only one noticeable oddity (the text goes down to within a quarter of an inch of the bottom of the page). In reading it, I appreciated the system of numbering topics within each chapter and it was easy to find my way around in. The parts which deal with straightforward electromagnetic theory are organised in a fairly conventional way, with a heavy dependence on vector manipulation in some sections.

Wangsness offers *Electromagnetic Fields* "for use in the usual year-long course in electromagnetism at an intermediate level given for advanced undergraduates". This is a straightforward aim and the text is a good conventional exposition of the subject, with few frills, up-to-date applications or fancy notions. Putting down Portis and picking up Wangsness one is aware of an enormous difference of attitude and approach. Wangsness gives a comforting feeling of old-fashioned virtue and I hope there is still a market for this. The chapters progress through Coulomb's law, the electric field, Gauss' law (so good to see the apostrophe correctly used), the scalar potential, and so on, in an orderly route which so many of us recognise from lecture courses and other texts. This is not intended as an unkind criticism because I rather like this book with its straight-laced academic air. There is, however, a dilemma: if you write a conventional book on a long-understood topic, in what ways is it better? I think the exercises are a particularly strong point in this case, with 130 actually worked out in the text and another 555 for the student. And the pointing out of common sources of error is helpful. On page 52, for example, the recipe for keeping source points and field points distinguished is good. In short, this is a conventional book, containing very little which could not have been written 50 years ago, but it is done thoroughly and with attention to detail.

It is important not to confuse this book by Lorrain and Corson with another on the same topic by the same authors but entitled *Electromagnetic Fields and Waves* (Freeman, San Francisco, 1970) abbreviated EFW below. The expressed aim is that the present book (*Electromagnetism,* abbreviated EM below) be used at freshman or sophomore (first- or second-year) level "either as an introduction to the subject for physicists and engineers, or as a last course in electromagnetism for students in other disciplines". I presume that those going further would find themselves at home in the other book, EFW, of which I have a good opinion. The present book, EM, I find very satisfactory, with some sense of excitement about it. The examples chosen are often of an applied and modern nature which gives a slight advantage over Wangsness, and there are three chapters on alternating currents which Wangsness leaves out altogether. On the other hand there is only one 22-page chapter on electromagnetic waves, which both Wangsness and Portis are strong on. The general level of production is excellent and the diagrams and problems are admirable, and I can see huge advantages in having a more advanced relation (EFW) to help both authors and readers over sticky patches. In such places, there are footnotes giving references to appropriate points in EFW. The price is, by today's standards, quite modest. It is an attractive book, obviously designed for a large market which I think it deserves to win.

The original version of *Electricity,* by Coulson alone, was published in 1948, and it was used successfully by undergraduates at Oxford and elsewhere for a considerable period. My view of it, as a student, was that it was helpful but rather highly condensed and therefore tough-going. Looking at the old edition now, it is clear to me that the difficulty was mainly that I was a physicist and that it was conceived and published as a mathematical text. Thus, there were very few references to experiments or to applications. The new edition has been prepared by T.J.M. Boyd, an applied mathematician, and I find it a very good job, though I would retain the reservation I mention above. There are noticeably more references to physical phenomena and particularly to plasma behaviour (all the five texts reviewed here give some discussion to plasmas). The units have been converted to SI and some minor improvements of style and coverage have been incorporated. But the main additions are the substantial four chapters at the end, on electromagnetic waves (Chapter 9), waves in bounded media (Chapter 10), the generation of electromagnetic radiation (Chapter 11) and relativistic electrodynamics (Chapter 12). These are good solid chapters which Professor Boyd has managed to write in such a way that the reader does not experience a style transition on beginning them. The work thus retains a sense of unity. Another improvement is in the use of computer methods for a variety of plotting tasks in which the results and the programs are given. The book is well produced and very reasonably priced. ☐

D.S. Betts has been a Lecturer in Experimental Physics at the University of Sussex since 1965.

General relativity

D.J. Raine

General Relativity and Cosmology. By J.V. Narlikar. Pp.279. (Macmillan: London, 1979.) £9.95. *General Relativity.* By J. Foster and J.D. Nightingale. Pp.192. (Longman: London and New York, 1979.) Paperback £5.45.

In June 1922, at the height of the deluge liberated by Eddington's confirmation of the bending of light by the Sun, *Nature* reviewed no less than seven books on relativity. In the whole of 1931 it reviewed one. Recent years have witnessed a revival of interest in relativity and a concomitant flux of literature at all levels, expecially as part of the centenary celebrations.

Einstein's theory is now half as old as Maxwell's electrodynamics. The fundamental theory has not changed, but much has happened to make the early expositions inadequate. First of all there has been a general diffusion of mathematical ideas, so that extended apologia for departures from Euclidean geometry, or for the mythical difficulties of the theory, are no longer necessary. Secondly, and paradoxically perhaps, with the hindsight of relativity we can now see Newtonian theory in a new way and general relativity can emerge as a necessary consequence of the special theory. Indeed, the teaching of general relativity would be so much easier if only Newtonian gravity were taught, as it so easily could be, in terms of the equivalence principle. But perhaps the most important change, already clear in the established modern texts, is the relentless strengthening of the empirical foundations of the theory which, despite the proclamations, was not finally confirmed by Eddington's expedition. This has culminated in the centenary year in the observations of the binary pulsar, which effectively confirm the existence of gravitational radiation, and play for general relativity a role similar to that of the Hertz experiment for electromagnetism. Thus general relativity has become as much a part of physics as Maxwellian electrodynamics — except that it is not useful for anything — and might be expected to give rise to a corresponding diversity of textbook treatments.

Professor Narlikar chooses to emphasise the physics of general relativity using only that mathematical dress that is decently necessary for proper calculation — no hint of a dual vector space, no definition of a differentiable manifold because, in the traditional expositions, these are not essential for local computations. Foster and Nightingale opt for a more mathematical approach which brings clarity to the structure of the theory but means that, within their limited space, they cannot go much beyond the classical results. Both assume an acquaintance with special relativity, although Foster and Nightingale give a review of this in an appendix.

Narlikar's book starts with a misprint in a sentence which is wrong anyway: how boring it must have been to write this opening! I was prepared to gird up my prejudices. But, in fact, most of the book is a masterpiece of pedagogic lucidity. Symmetries of spacetimes are dealt with properly in terms of Killing vectors, the theory of orbits in the Schwarzschild solution is developed in terms of effective potentials, Price's theorem in the collapse to a black hole and the four laws of black-hole dynamics all receive a mention. There is even space for derivations of the classical cosmological tests. It is a pity that the Robinson-Carter theorem on the uniqueness of black-hole solutions is missing, and that the results from the binary pulsar presumably came too late for inclusion. And the discussion of the black-hole candidate Cygnus X-1 is unfortunately, to put it politely, slightly confused.

Where I really feel obliged to take issue, however, is with the references to current areas of research activity. It is true that what is intended is only a glimpse and not a survey, and nowhere are they explicitly claimed to be representative. It is true also that most authors avoid the potential embarrassment of Time's sickle compass by leaving out where in doubt. The lecture format helps here (and here only) in lending an impression of informality. Nevertheless, I feel that Professor Narlikar comes dangerously close to confusing for the reader those matters of personal interest and opinion and the consensus view. The general consensus, right or wrong, is, for example, that quasars are cosmological, that the Hoyle–Narlikar theory is neither in accordance with Mach's principle nor even a putative solution to the problem of the existence of spacetime singularities, that the Steady State Theory is under something rather more substantially earthly than 'a cloud', that the Kaluza–Klein five-dimensional theory is awaiting only the funeral arrangements and that it and indeed f-gravity are less likely to produce a unified field theory than the unmentioned supergravity theories, and that interesting progress is being made in quantum gravity by evaluation of the path integral. The uninformed reader may well be left with a false impression of the main thrust of current thinking, which is a pity in such an otherwise admirable exposition.

The main danger in a mathematical approach to the elements of the theory is that general relativity emerges from the differential geometry as one amongst many possible theories, the geometrisation of gravity appearing as pure artistic creation or conventionalism. The idea that the equivalence principle drives one to this vision gets lost somewhere in the multilinear mappings. On the other hand, Foster and Nightingale do find space for explicit calculations as well as general results, so that a feeling for the inner working of the theory is communicated. The numerous exercises for the reader help in this, being used here to illustrate the theory rather than to develop it further as in Narlikar's book.

The special aspect of both of these books that distinguishes them from the established modern works such as those of Weinberg and of Misner, Thorne and Wheeler is brevity (a distinction which in relation to the latter is fairly universal). Of course, brevity of exposition does not guarantee greater rapidity of digestion. In fact, Narlikar achieves a masterly conciseness, and Foster and Nightingale

AI | EUP

Expert Systems in the Micro-electronics Age
Donald Michie *editor*
0 85224 381 3 293pp £10
The exciting contribution of AI to Knowledge Engineering is vividly demonstrated in this collection, derived from an AISB seminar. An expert system is a computing system that embodies knowledge concerning some specific area of human expertise sufficient to be able to do duty as a skilful and cost-effective consultant. The papers deal with the principles of the systems as well as with specific programs, and contributors include Feigenbaum, Howe, Sloman, McCarthy and Robinson.

Advances in Computer Chess 2
M. R. B. Clarke *editor*
0 85224 377 4 148pp £7
Addressed primarily to AI specialists, but will interest the wider chess fraternity. No serious player can fail to be stimulated by the insights into, e.g., endgame theory that computation is opening up, and many of the papers in this book have as much to offer the active player as the theoretician. Contributors include Beal, Clarke, Bramer, Kopec, Michie, Kent and Birmingham.

Artificial Intelligence: an introductory course
Alan Bundy *editor*
0 85224 340 5 261pp £6
These lightly edited lecture notes of Edinburgh's 'ordinary' introductory course on AI have been widely welcomed, in Europe, North America and Japan, as the best teaching tool currently available. The notes are divided into six sections: Representations of Knowledge, Natural Language, Question Answering and Inference, Visual Perception, Learning, and Programming.

Logic : Form and Function the mechanization of deductive reasoning. J. A. Robinson
0 85224 305 7 318pp £12
The first half of the book attempts to clarify the theory of the predicate calculus, and the second half traces the development of the theory towards the goal: that deductive reasoning can be mechanized. The discussion culminates in a detailed account of the author's working program for showing 'what follows from what'.

now in paperback at £7.50

concentrate on a proper mathematical development of the classical results.

But for a real example of how to write concisely we have to turn to the appendix of Foster and Nightingale. There we are told that if Newtonian dynamics and not special relativity were true, the two mile Stanford linear accelerator would need to be only one inch long. In a nutshell here is the essence of the status of special relativity; no technological details, no experimental arrangements, for these can be found elsewhere, but a correct overall view in a single picture. Would that it were all so simple. □

D.J. Raine is Lecturer in Theoretical Astrophysics at the University of Leicester, UK.

Basic chemistry

C.A. McAuliffe

Introduction to Modern Chemistry. By E. Meyer. Pp.527. (Prentice-Hall: Hemel Hempstead, UK, 1979.) £11.65. *Chemistry: A Conceptual Approach.* By C.E. Mortimer. Pp.815. (Van Nostrand Reinhold: Wokingham, UK, 1979.) £7.50. *Basic Chemistry.* By G.H. Miller and F.B. Augustine. Pp.420. (Harper and Row: London and New York, 1979.) £6.45. *Chemistry for the Consumer.* By W.R. Stine. Pp.496. (Allyn and Bacon: Boston, London, Sydney and Toronto, 1979.) £13.55. *Fundamentals of Chemistry.* By F.H. Redmore. Pp.711. (Prentice-Hall International: Hemel Hempstead, UK, 1979.) £12.30.

I RECENTLY heard it said that one reason graduates from American and Japanese universities are more adaptable when entering industry than are UK graduates is that they benefit from a relatively non-specialised, more inter-disciplinary course than that which UK students enjoy. I think that there may be something in that notion. Certainly, I am, after seventeen years of fairly intimate contact, still amazed at the job which US universities do for the disparate student-entry they receive. The books reviewed here demonstrate quite well, in what they set out to do, just what a varied body they are aimed at. Indeed, it is a mistake for persons not familiar with US colleges not to realise that there is immense variation in college entries both in terms of preparation and ability of freshmen students. This is directly related to standards in US high schools, where teachers are frequently qualified in education but ill-qualified in the disciplines they teach, and also to the fact that since almost all high school students graduate and are thus, in many States, qualified for entry to State universities, the intellectual abilities span the whole spectrum. In turn, the requirement by many universities for students to pass a basic science course sets a daunting task for would-be authors of basic chemistry texts, but one that can be professionally and financially very rewarding for those who are successful.

Three of the books discussed here are directed towards students who either have never before had a chemistry course or have had very small exposure to chemistry. The text *Introduction to Modern Chemistry* by E. Meyer has for its first sentence in the Preface: "Teaching a course in basic, modern chemistry is often a unique educational experience for the instructor and students alike." It might well be a rare educational experience for a student to teach a course in basic chemistry, but if one should attempt it this is not the text to refer to other students. I think it is sloppy in Chapter 1, where the word gas is carefully defined a number of times, to also to refer to a gas guage (meaning gasoline guage). The introductory chapters seem to be written at an extremely elementary level. Despite my introductory paragraph, I feel it is insulting to any college student to include a half-page illustration of a mediaeval king with a pipe running from his nose to his finger tip to say that early standards of length had some anatomical origin.

There are two and a half pages of photographs of balances (pp. 34–36), and in the worked Example 2-4, one-third of a page is needed to convert 98 mm to 9.8 cm. On page 63 of this college chemistry text it is stated "Each element is associated with a unique symbol . . . . In place of carbon, we write C; for chlorine, Cl; for sodium, Na; and so on." Yet, only a little later (pp. 110–125), the Bohr model of the atom and quantum mechanical model are discussed.

It appears to me that authors such as Meyer should ask themselves just who they really are writing for. It is not conceivable to me that one can aim introductory chapters at students who cannot be numerate and are slow to learn, and expect these people to go so quickly from converting °C into °F to a discussion of the emission spectrum of the hydrogen atom. These same criticisms apply to *Basic Chemistry* by G.H. Miller and F.B. Augustine. On page 11, worked Example 2.1 takes two-thirds of the page to calculate how many centimetres there are in 25.00 m. Worked Example 3.3 answers the question "What is the mass of a chromium atom" with the unhelpful: "It is 52/12 the mass of a carbon atom." On page 105 the section on oxidation numbers is inconsistent and downright misleading. As in many such texts there appears to be poor judgement as regards what it is that is important for a chemistry book to contain; for example only two pages are devoted to the chemical properties of hydrocarbons.

The third of these volumes, *Fundamentals of Chemistry* by F.H. Redmore, is to be recommended. It does contain the trivial chapter (centimetres into inches), but after that it does assume the reader is of at least average intelligence and, in contrast to the Meyer and Miller/Augustine books, it is tightly written, and, like a number of good freshman chemistry texts, is able to simplify quite difficult theoretical concepts. Thus, simple molecular orbital and crystal and ligand field theory are very well presented. The structure of the atom is introduced early (Chapter 4) and is nicely done. I particularly liked Chapter 21: Periodic Variations. Redmore deals with the Born–Haber cycle — the first two books do not.

The fourth edition of *Chemistry. A Conceptual Approach* by C.E. Mortimer is, we are assured in the Preface, "the most student-oriented edition" yet. (Whatever next? Orienting textbooks towards students!) But it is a good book and deserves to have lasted so long. Chapter 2 on atomic structure is excellent, and I also particularly liked the chapters on kinetics and thermodynamics. The standard of text and diagrams is high almost throughout (but I did find that molecular orbital schemes using circles for s orbitals and squares for p orbitals was intrusive and detracted from the otherwise well produced figures). There are some more serious objections — wave mechanics is dealt with beginning on p. 41, whilst the concept of a mole is not introduced until p. 152; the student who can understand simple wave mechanics surely doesn't need to have explained what the term molecular weight means (also on p. 152). I also feel that standard and non-standard states need clearer definition.

Chemistry for the Consumer by W.R. Stine is aimed at the non-scientist and intends to provide enough chemical knowledge and principles for an understanding of such concepts as nuclear and radiochemistry, agricultural chemistry, food chemistry, medicinal chemistry and pollution problems. It just does not quite make it. I find it hard to imagine just to whom the book will appeal. If Stine would write such a book for the scientist he might achieve a more worthwhile object. I think this book has a most severe drawback; figures containing rather complicated chemical formulae coupled, albeit, with simplistic text, does not make for an understanding of chemistry by the non-scientist. Furthermore, although Stine says in the Preface that he hopes the reader will "gain a better understanding . . . of such things as energy, food, . . ." only passing reference to nuclear energy is made and the most important energy-capturing chemical system, photosynthesis, is briefly mentioned in the production of carbohydrate — but the non-scientist will probably not realise that photosynthesis converts solar energy into chemical energy. The word energy does not appear in the index. ☐

C.A. McAuliffe is Reader in Chemistry at the University of Manchester Institute of Science and Technology and Adjunct Professor of Chemistry at Auburn University, Alabama.

Unifying concept in organic chemistry

R. C. Poller

Organic Stereochemistry. By Henri Kagan. Pp.166. (Edward Arnold: London, 1979.) Paperback £4.95. Translated from *La Stereochimie Organique.* (Presses Universitaires de France, 1975).

ENGLISH LANGUAGE texts of organic chemistry are markedly derivative, so one might expect Professor Kagan's book to contain some fresh insight into a subject where the French contribution has been central. The reader will not be disappointed. Stereochemistry is seen to be a unifying concept in organic chemistry and it is satisfying to see a diverse range of topics from conjugation, through kinetic versus thermodynamic control, to pericyclic reactions discussed from this single standpoint. The treatment is from first principles and as rigorous as could be expected in a work of this size, though only a brief introductory account of the more marginal topics is possible.

All who teach stereochemistry will have been grateful for the moves toward a more logical and consistent terminology which have been evident in recent years. Substitution of the term "chirality" for the anthropomorphic "handedness" is allowing the too vague "dissymmetry" and the often misapplied "asymmetry" to fall into disuse. The clear division of stereoisomerism into enantiomerism and diastereoisomerism has liberated us from having to tell our students that the optically inactive meso tartaric acid is an optical isomer of the (+)-form. We no longer have certain cyclic compounds uneasily carrying the banners of both optical and geometrical isomerism and the universally applicable RS/EZ system of configurational notation is especially welcome.

We cannot expect that a text originating in a foreign language should simultaneously present novel viewpoints and a sensitivity to the English nomenclature. Kagan and his translators have chosen to use a mix of the old and new terminology. The deliberately literal rendering of the original has, nevertheless, led to some unfortunate semantic choices, for example, where the usual meanings of the terms "racemic compound" and "racemate" have become exchanged. Finally, although this is an inexpensive book, one has the right to expect a higher standard of proof-reading and, more importantly, better diagrams. The latter are small, not always clear, and occasionally confusing.

Despite these caveats this is a valuable book which is commended to all those who have an interest in organic stereochemistry. ☐

Inorganic chemistry

H. A. O. Hill

A Theoretical Approach to Inorganic Chemistry. By A. F. Williams. Pp. 316. (Springer: Berlin, Heidelberg and New York, 1979.) DM98; $53.90.

To my surprise, I greatly enjoyed reading *A Theoretical Approach to Inorganic Chemistry.* Usually when I hear 'theoretical' and 'inorganic' used in conjunction I reach for my revolver. However this admirable book is so full of good sense that all previous prejudices were overcome.

The first chapter contains the essence of quantum mechanics and atomic theory. The only constitutent lacking is the relationship between complex eigenfunctions and the angular momentum operator. The concepts culled from quantum theory are then used to describe polyelectronic atoms and ions, laying to rest in passing such a shibboleth as 'the stability of the half-filled shell'.

The key features of molecular orbital theory are succinctly described in Chapter 2 of which a salutory section discusses hybridisation. The application of molecular orbital theory to the interpretation of the structures of molecules is the subject of Chapter 3 and how best to begin than with a discussion of Walsh diagrams. The section on transition metal compounds is interesting though I was sorry to find the ligand field parameters, Δ and 10Dq, treated as if they are necessarily synonymous; and even more to find the Jahn-Teller effect introduced on page 82 without a proper statement of the theorem. However, the author makes some interesting comments on organometallic compounds, not least the description of the "eighteen-electron rule as an example of electron counting rules that work for no especial reason".

The discussion of electron-deficient compounds (or rather 'compounds for which the theory previously provided was deficient') and cluster compounds is very valuable. It was good to find the same ideas applied to solids, often neglected in popular modern texts. In the chapter on electronic and magnetic properties, the ideas of C. K. Jorgensen find a suitable home; they have long deserved wider exposure. The Jahn-Teller theorem is now discussed more rigorously and as a bonus (?) a brief mention is made of the second-order effect. It is a pity that the author, having kept firmly to SI units in the rest of the book, reverts to c.g.s. units when discussing magnetic properties.

An important chapter contains an account of alternative methods and concepts. Whether the X-method warrants its position at the beginning of the chapter is debatable. The valence bond model and ionic model are well treated and the section on Valence Shell Electron Pair Repulsion should be essential reading for all undergraduates. It is hard to think of an idea that has gained such wide yet uncritical acceptance. The section on "thermodynamics and inorganic chemistry" seems a little out of place in this company especially as it is followed by "Useful Concepts in Inorganic Chemistry". Some might take issue with that title since it includes a description of 'Hardness and Softness' which even warrants a subsection on 'theoretical aspects'. Still, as the author states, "as with other concepts in inorganic chemistry, we should know when they lead us astray". I found the account of "Mechanism and Reactivity" and "Descriptive Chemistry" valuable but that on "Physical and Spectroscopic Methods" less so though even here, the words, though few, are wise. Each chapter has an excellent bibliography.

I have no hesitation in recommending this book to both those who teach and those who study inorganic chemistry. This is especially so for those about to take examinations though by this time it may be too late for the remedial properties of the book to take effect. We should be grateful to the author for sharing his insight with us. □

H. A. O. Hill is Lecturer in Inorganic Chemistry at the University of Oxford, UK.

Physical principles of photochemistry

G.S. Beddard

Principles of Photochemistry. By J.A. Barltrop and J.D. Coyle. Pp.213. (Wiley: Chichester, UK and New York, 1979.) £4.95.

THERE are now available several photochemistry textbooks; their emphasis is on photochemical reactions but they deal only briefly with basic photophysics. An alternative approach, such as is in large part provided by Barltrop and Coyle's book, *Principles of Photochemistry,* should be welcomed by undergraduates and postgraduates alike. The emphasis of the book is on photophysics rather than photochemistry (consequently the title is inexact, for only in Chapter 6 is photochemistry really discussed).

After a brief introduction in Chapter 1, Chapter 2 describes time-independent excited-state properties. The Born–Oppenheimer approximation, Franck–Condon factors, spin-orbit coupling, $n\pi^*$, $\pi\pi^*$ and charge transfer transitions are covered. Also included are excited-state geometry changes, acid–base properties and solvent effects. Curiously, though, simple laser theory (which is dealt with too briefly, anyway) is also included in Chapter 2 rather than in Chapter 3, which deals with time-dependent properties, or in Chapter 5, in which techniques for examining reaction mechanisms are explained. Chapter 3 describes excited-state kinetics, fluorescence, phosphorescence, triplet–triplet annihilation and radiationless processes. The last topic is discussed simply but clearly although in a book of this type a more detailed discussion could have been included, especially considering the wealth of information now available. Quenching of excited states by excimer and exciplex formation, electron transfer and electronic energy transfer are treated clearly and concisely in Chapter 4. The kinetics of these quenching mechanisms are also detailed.

Methods of investigating reaction mechanisms, such as trapping intermediates, CIDNP or flash photolysis, occupy half of Chapter 5. No examples of transient flash spectra are given and the most important modern techniques of submicrosecond flash photolysis are only mentioned in passing. Similarly, measurement of singlet lifetimes is hardly mentioned except for an example in Chapter 3 of the rarely used two-photon fluorescence technique. The best feature of this chapter are the pages analysing quenching kinetics leading to nonlinear Stern–Volmer plots.

In summary, this book contains a great deal of useful and, on the whole, carefully presented information on the photophysical properties of excited states. Photochemical reactions are only briefly (12 pages) studied. The description of the experimental techniques is a little out-of-date and excludes important techniques such as single-photon counting and nanosecond and picosecond flash photolysis. The book is, however, well written and easy to read; the problems at the end of the book are also interesting and require some thought. The restriction of mathematical treatments to the minimum while retaining clarity should encourage less mathematically minded students to use this book. □

G.S. Beddard is Assistant Director of Research at the Davy Faraday Research Laboratory, Royal Institution, London, UK.

Atomic collisions

H. Kleinpoppen

Atomic and Molecular Collisions. By Harrie Massey. Pp.309. (Taylor and Francis: Basingstoke, UK, 1979.) £12.

AT LAST, one can say, there is an introductory authoritative text book available on atomic and molecular collisions. The author, Sir Harrie Massey, the grand old master and pioneer in the field, has written this introductory book shortly after the completion of the monumental and comprehensive monographs on atomic collisions (edited by him and his colleagues). The introductory book is suitable both for experts and non-experts in the field and particularly for undergraduate students. The book fills a gap and will certainly be welcomed by the scientific community.

The difficulties in preparing an introduction to atomic collisions mainly result from the nature of the subject. While introductory textbooks on solid-state physics or atomic spectroscopy, for example, can be restricted to the selection of stationary physical processes (which are dealt with by stationary quantum mechanical formalism), atomic collisions require dynamical methods and approximations over a wide range of applications. Even for the simplest colliding system such as scattering between electrons and atomic hydrogen no exact theoretical solutions are available. It was not possible to include sophisticated problems of atomic collision theory in an introductory text book. The book does contain a discussion and interpretation of the collision data required to develop basic concepts of quantum mechanics such as particles and waves and their dualism, the uncertainty principle, and the quantum mechanical description of scattering cross sections. Chapters on such topics include elementary descriptions of atomic and molecular structure. Appropriate experimental technology has been explained within the main text. Only a limited selection of topics on atomic collisions could be considered in this type of book. Nevertheless, the author has covered a broad range of the large field of atomic and molecular collisions and he has succeeded in exposing the full scope of the subject. It is obvious that the selection and detailed discussion of these most interesting topics reflect the mastery and long experience of the author as one of the pioneers in the field. The order of the topics of the book follows the traditional scheme, which is mainly guided by selecting projectiles and atomic and molecular targets: elastic and inelastic electron-atom scattering (including resonance effects, capture, recombination and attachment processes), collisions between neutral atomic and molecular systems, ion-atom collisions, photoionisation of atoms and molecules, and photodetachment of negative atomic and molecular ions. The last chapter deals with atomic collisions in the Earth's atmosphere, the solar corona and interplanetary space. Seven appendices supplement information mainly on experimental technology.

Each chapter, each section and even each line of the book is excellent, and it reveals the great devotion (and love) of Sir Harrie to the field of atomic collisions. The detailed discussions on selected topics (for example, the Ramsauer-Townsend effect, the glory and rainbow structure in atom-atom collisions, or the selected collision processes in the ionosphere) are of highest pedagogical standard. As an introduction the book represents without any doubt a break-through; it will be a challenge and precedent for future authors. This is the more important as the research field of atomic collisions is still in an explosive state: new exciting results from atomic angular correlations, from spin effects in electron-atom scattering, and from collisions with laser excited atoms will soon require new editions of introductory textbooks. Sir Harrie has paved the way (as he often did in research) for such future tasks. □

Nuclear physics

J.M. Reid

Elements of Nuclear Physics. By W.E. Burcham. Pp.422. (Longman: Harlow, UK, 1979.) £7.95.

THE accommodation of a rapidly expanding subject is a constant problem in the construction of undergraduate course syllabuses. The problem has been particularly severe in the case of nuclear physics over the past decade. The generally accepted separation of elementary particles (or high energy physics) as a subject in its own right has not produced any long-term amelioration in the face of the constant ferment of new ideas and approaches in both the low and high energy fields. Defined by the author of the volume under review as "the understanding of the nature of matter at a level deeper than that of the electronic structure of atoms, molecules and solids but not so deep as that of the particle structure of the proton and the neutron", nuclear physics must always find a place in some form in any course claiming to span matter from the macro to the micro level. The case for the study of the subject on the grounds of its practical applications has changed dramatically from the time of its emergence from the shadow of restricted work on nuclear based weapons in 1945. It was then, optimistically, to understand the processes about to provide a solution to the world's recognised energy problems. Today the case might be to provide a background understanding of the use of nuclear techniques in order to circumscribe the risks involved in the reluctant application of these techniques to socially vital problems.

However, Professor Burcham's latest textbook is not concerned with the practical applications of nuclear physics; it sets out to provide a description of the present state of nuclear structure measurements and to demonstrate what can be learned by the application of quantum mechanics to nuclear models. A previous well founded knowledge of atomic physics, relativity and quantum theory and some acquaintance with the rudiments of nuclear physics are required for maximum benefit to be obtained from this book, as the containment of the material within the limits of a single volume is achieved by very compressed treatment of matters assumed covered in earlier courses. Space is thus gained for a thorough treatment of the single particle shell model, the collective model and the unified model. The final three chapters in which the whole field is reviewed from the standpoint of the electromagnetic, the weak and the strong interactions are particularly valuable. A generous supply of numerical problems is included chapter by chapter and the solutions of a selected number of these are given in an appendix.

The final-year undergraduates for whom the book is designed will in no sense find this an easy text. Those among them who have postgraduate research ambitions will find it an excellent base on which their future studies in nuclear or elementary particle physics can be securely built. In fact for several years to come the text should be suitable reading for postgraduate courses in the field. The volume is put together with the neatness and the authority to be expected from an experienced and respected practitioner in this area of research. □

Applying electrodynamics to astrophysics

M. Rowan-Robinson

Theoretical Physics and Astrophysics. By V.L. Ginzburg. Pp.464. (Pergamon: Oxford, 1979.) Hardback £25; paperback £10.

PROFESSOR ter Haar has performed the arduous task of translating this advanced textbook by a prominent Russian astrophysicist admirably. Impressive though this book is in several respects, however, I feel it needed a good deal more work on it before it was published in a Student Edition.

A more accurate title for the book would have been *A Treatise on Electrodynamics, with some Applications to Astrophysics.* Most of the book consists of rather academic discourses on the themes of those great books by Landau and Lifschitz. However, Ginzburg does not have quite the same ability to illuminate abstract principles with simple and concrete examples. The absence of any sub-headings within the chapters makes the book hard to read and limits its usefulness as a work of reference. The neglect of the Western literature on the subject in the references cited (over 80% of the references are Russian and about a third are to papers by Ginzburg and coworkers) will not commend the book to other workers in the field, despite Ginzburg's plea in the Preface to the English edition that this was not so noticeable in the Russian edition and that the book was based on a lecture course. It is precisely this kind of deficiency in a lecture course that one expects to be made good in a textbook. The publishers have managed entirely to omit the first four pages of Chapter 3.

The most interesting and useful chapters for the general astrophysicist will probably be Chapter 5 on synchrotron radiation and Chapters 15–17 on cosmic-ray, X-ray and gamma-ray astronomy, though the review of the observational situation in these latter areas is rather out of date (the Russian edition appeared in 1974). Not all the formulae given are of sufficient accuracy for contemporary astrophysical applications. In the formulae for bremsstrahlung, for example, the Gaunt factor is assumed to be unity: some space could surely have been found for a discussion of the exact value.

The book remains, however, an important one by a major physicist. The specialist in electrodynamics will find it a useful review of Russian work in the field and the theorist in high-energy astrophysics will find some parts of the book valuable. □

Michael Rowan-Robinson is Reader in Astronomy at Queen Mary College, London, UK, and Gresham Professor of Astronomy at the City University.

Introducing meteorology

J.S.A. Green

Fundamentals of Meteorology. By L.J. Battan. Pp.321. (Prentice-Hall: Hemel Hempstead, UK, 1979.) £10.90. *The Atmosphere.* By Lutgen and Tarbuck. Pp.413. (Prentice-Hall: Hemel Hempstead, UK, 1979.) £10.90.

MOST of us have a vested interest in meteorology, and any books like those reviewed here, that seek to explain the intricate details of the subject to a wider audience, are always welcome. These two books summarise modern meteorology for the 'non-mathematician', by which the authors mean one not familiar with 'differential calculus'. Both books cover many topics of interest to a general reader, such as air pollution (supersonic airliners come in for substantial unquantitative criticism), clouds, the generation of rain, storms and climate. Curiously, their contents overlap by some 75%. To a scientist used to a uniform system of units, they both show a wide variety. One has a useful table of densities of common substances expressed in g cm^{-3}, as well as in kg m^{-3}. That the figures in one column are just 1,000 times the figures in the other might well strike the unitiated as an odd thing for scientists to pay attention to. A variety of basic units is used: calories, watts, feet, metres, knots, metres per second. Presumably the aim is to use units familiar to the reader, but one loses something of scientific nicety. The literary style is inexorable rather than objectionable: " . . . precipitation data for localities in selected precipitation regimes . . ." is typical.

My only major reservation concerns the sort of information that the authors have tried to present. A typical, but not unimportant, topic concerns the geostrophic wind. This blows along the lines of equal pressure, not across them from high to low pressure, as one might naively suppose. If I had to start from my first sight of Newton's laws of motion in order to arrive at this result, then I think I would feel cheated. The important fact is that the Coriolis acceleration is at right-angles to, and proportional to, the wind and not as one would expect, along the direction of the change in velocity as we usually measure it relative to the Earth. The point is made by having an experimenter, who used to be a golfer (but who now uses intercontinental ballistic missiles), fire missiles from the North Pole while the rest of the Earth moves past relative to the missile. But this rightly leaves me unimpressed because the golfer is in a situation where the real acceleration of the missile is zero, and the apparent acceleration seen from the Earth is fictitious. For geostrophic motion where the Coriolis acceleration balances the force due to the pressure field, it is exactly the other way round: the relative acceleration is small but the real (Coriolis) acceleration is large. Thus, trying to represent what really happens in terms that are too simple, may mislead that thoughtful non-mathematician. It might be better to tell him that geostrophic balance happens and that it is because of the rotation of the Earth. However, if you go and study mathematics, you can find the inevitable connection between the Newtonian laws and the geostrophic wind.

One expects to find authors representing such differences in philosophy that this topic highlights, and the books do summarise much modern meteorology, with particular emphasis on conditions in North America. Certainly one (but not both) would be a useful teaching aid for any non-meteorologist wishing to give a course on meteorology to American undergraduates. They are a useful *Introduction to Meteorology,* with the mathematical bits left out, and nicely illustrated by satellite pictures. To me they seemed to lack something of the enthusiasm of the authors for their subject. One of them recommends Minnaert's book, *Light and Colour in the Open Air,* to those interested in optics. Minnaert starts his book: "A lover of Nature responds to her phenomena as naturally as he breathes and lives." Now that is the sort of attitude I think we can expect to put before this person who has failed to acquire 'differential calculus' amongst his grades, and it does not come over to me from either of these texts.

Let us hope that their readers will absorb the philosophy and enthusiasm of Minnaert, as well as the useful factual information which he will find in these books. □

J.S.A. Green is Reader in Physical Climatology at Imperial College, University of London, UK, and Head of a Group teaching meteorology at MSc. level to students with a first degree in mathematics or physics.

Principles of applied geology

John Knill

Principles of Applied Geophysics. By D.S. Parasnis. Pp. 275. (Chapman and Hall: London, UK, 1979.) Hardback £8.50; paperback £4.95. *Geology for Civil Engineers.* By A.C. McLean and C.D. Gribble. Pp. 310. (Allen and Unwin: Hemel Hempstead, UK, 1979.) Paperback £5.95.

THESE two books, while illustrating quite different aspects of industrially orientated geology, have also somewhat different status as books. Parasnis' book is the third edition of a well known volume which has been reprinted three times between editions, while McLean and Gribble have written a brand new text.

Geophysics has been for many years the major large-scale exploration tool applied to hydrocarbon search, is also widely used in the mineral and construction industries and is now of increasing significance in ocean and land-based shallow crustal studies based on artificial explosions. This text has an extremely systematic approach, separate chapters dealing with magnetic, gravitational, electrical and seismic methods with additional chapters on induced polarisation, electromagnetic methods, radioactivity techniques and miscellaneous methods including borehole logging. The popularity of this book as a brief but comprehensive survey of the field of technique, processing and interpretation in applied geophysics is well justified. The new edition includes a new chapter on induced polarisation, derivation of formulae has been put into appendices to aid the flow of the text and the units and symbolism have been standardised and clarified. This book will undoubtedly continue to fulfill a need for an inexpensive but comprehensive presentation ideal for the student at undergraduate and postgraduate level.

The textbook by McLean and Gribble is primarily directed at the undergraduate civil engineer and provides a basic introduction to geology, and to those aspects of applied geology relevant to the construction industry. The book has a fresh, attractive appearance and the cover is particularly striking, tending to draw the eye, and possibly the wallet. The authors have thought carefully about the philosophy of the book but, in the event, selected the traditional balance between geology and engineering geology on an equal basis. The early chapters review minerals and rocks, engineering soils, stratigraphy and structural geology. The contents are deliberately selective, focusing on those terms believed by the authors to be of the greatest importance to the engineer. The book then turns to, and deals with, ground and surface water, site investigation including geophysics, rock classification and materials, excavations, slope stability, dams and reservoirs, and tunnels. The chapters on engineering geology draw upon several case histories which are briefly illustrated. There are many clear diagrams and photographs, and each chapter is supported by references. The authors have clearly made a careful attempt to cover the field but there are gaps, some of which are important. For example, there is no reference to soft ground boring techniques, which is surprising after the detailed consideration given to engineering soils, and foundations appear to be wholly omitted. The authors have drawn mainly upon their own experiences in developing the book and occasionally the text jars to the expert mind. A little more honing of the text in parts would have helped because, to the reviewer, occasional sections or phrases were inappropriate in relation to either conventional practice or the conclusions drawn. However, there is no doubt that the audience for whom the book has been written will find it easy to read, interesting and possibly stimulating. □

John Knill is Professor of Engineering Geology and Head of the Department of Geology at Imperial College, London, UK.

Chemical ecology

P.E. Howse

Introduction to Chemical Ecology. By M. Barbier. Translated by M. Ferenczi. Pp.128. (Longman: London and New York, 1979.) £3.95.

MICHEL BARBIER, a natural products chemist, attempts in this book to review our current knowledge of toxins, defensive secretions, plant allomones and sterols, and to define chemical ecology as a discipline.

My first criticism concerns Mr Ferenczi's translation, which does a disservice to the author. He frequently fails to find the appropriate English idiom, resulting in absurdly tortuous expression as, for example, in the quotation in the paragraph below. His evident lack of familiarity with entomology leads to the common silkworm (*Bombyx mori*) being described several times as a "butterfly" or as the "mulberry tree Bombyx". Worse still, the gypsy moth is described as "the predatory forest butterfly", and the boll weevil as the "predatory cotton plant beetle". It is unfortunate that the publishers did not, apparently, check the translation for syntax, idioms, or use of common names. There are also many minor errors that should have been picked up in proof.

My second argument is with Barbier's concept of chemical ecology, to which he devotes much of two chapters, a preface and an epilogue. He defines chemical ecology as "the science of chemical relationships between living organisms or between living organisms and the mineral world". This allows him to include pollution problems and aspects of nutrient cycling in the same ambit with animal secretions, hormones and allelochemicals, and to suggest that the whole can lead to a "new philosophy of man" which predicts "the absolute necessity of changing rapidly man's psychology" (that is, in his approach to environmental problems). He (and Ferenczi) make some rather trite observations in terms that render them almost incomprehensible: ". . . death is a primary condition of life . . . to develop life is akin to increase in death potentials, including various forms of pollution. In this instance, the contradiction is not thought to be fundamental, but rather to be the mirror image of a progress vector". This kind of writing will discourage and confuse any reader, but I firmly believe that such philosophical flights are unnecessary anyway.

Chemical ecology is surely a search to explain interrelationships between organisms and their environment in chemical terms, rather than in terms of traditional ecological factors like climate, niche, food resources, and so on. Chemical ecology is now at a very exciting stage: we now have a good fund of information on the chemistry of animal secretions used in communication and defence, secondary plant substances, and the like. We know very little about the adaptive function of these, but that information is beginning to accrue and the general principles for which Barbier is casting around will be found in the field in coming years. Ecology in general has been concerned for many years with pollution and its effects on natural equilibria, but the methodologies, concepts and supporting disciplines are distinct from those involved in explaining interrelationships between, say a heliconid butterfly, its food plants and its predators, in terms of chemical factors. □

P.E. Howse is in the Chemical Entomology Unit at the University of Southampton, UK.

Ecology booklets

P. D. Moore

Island Ecology. By M. Gorman. Pp.79. (Chapman and Hall: Andover, UK, 1979.) £1.95. *Vegetation Dynamics.* By J. Miles. Pp.79. (Chapman and Hall: Andover, UK, 1979.) £1.95.

THE days are gone when undergraduate texts adequately embraced broad subjects. The development of a whole range of specialist studies even within a field like ecology has rendered it difficult for any one author to deal effectively with the rapidly growing body of information and ideas. Publishers are facing this problem in one of two main ways; either they are turning to edited textbooks in which each chapter has a different author (for example, *Thoretical Ecology* edited by R.M. May (Blackwell: Oxford, 1978)) or they resort to part-works in which various specialists are responsible for brief booklets which are intended to fit together into a uniform whole. This approach has been most effectively pioneered by Edward Arnold in their Institute of Biology series, which now runs to over a hundred items.

Chapman and Hall are now entering this market by producing an ecological series designed on similar lines and edited by George Dunnet and Charles Gimmingham at Aberdeen. The first two issues in this series are reviewed here.

Vegetation Dynamics by John Miles, of ITE (Institute of Terrestial Ecology), Banchory, is essentially a study in plant succession and it represents a very thorough and up to date review of this area of ecology. It begins by considering the ways in which ecologists view vegetation, with emphasis upon the divergence in viewpoints since Gleason and Clements. Mechanisms of vegetation change are dealt with fairly briefly, which is an unenviable task since such wide subjects as seed dormancy, competition and allelopathy need to be covered in a single chapter. This is not entirely satisfactory, since the subject warrants a book on its own and much has to be conveyed by examples, and no example can ever fully typify an ecological generalisation. In particular, more space could have been given to a consideration of stability, its definition and conceptual value. As it is, one is left with an uncritical statement of Horn's logical, but somewhat unhelpful, definition relating stability to speed of return to the equilibrium state.

A consideration of cyclic changes concentrates upon the well known A.S. Watt examples, plus regeneration of *Abies* forest. It would have been sensible to develop this idea more fully in its application to the persistence of the climax state. The regeneration mosaic of the climax, as demonstrated by such workers as Loucks, Forcier and Hope-Jones, provides an interesting comparison with the cyclic phenomena described in such detail by Watt.

There is finally a consideration of the role of grazing animals, another subject in which generalisation is difficult. Perhaps its influence on population dynamics of plant species could have received more emphasis.

One area which is rather neglected in the booklet is the total ecosystem view of succession, but perhaps the title was chosen specifically to avoid this issue. Nevertheless, a more complete work would have resulted if the Odum analysis of succession (which is mentioned) had been critically discussed. Such subjects as energy flow and nutrient cycling are central to an understanding of succession.

Overall, I wish the booklet could have been a little longer to include these additional items. Within the spatial confines of 80 pages, Miles has produced an extraordinarily extensive review of over 300 papers and has collated them in an interesting and thought-provoking manner. I shall certainly direct students towards it.

Island Ecology by Martyn Gorman is concerned with a very much more confined topic than vegetation dynamics and thus is more easily dealt with inside the restricted space available. The subject is again one which is of interest to many ecologists because of the manner in which the biogeographical principles propounded by McArthur and Wilson have been applied generally to fragmented habitats at a variety of scales.

The bulk of this booklet is concerned with true islands and their biology, but the idea of 'habitat islands' is always held in mind. For example, when considering dispersal, reference is made to B.N.K. Davis' experiments with nettle clumps and their invasion by invertebrates.

The mathematics of island biogeography is dealt with in a clear and simple manner and will provide a useful starting point for introducing students to this concept. The evolutionary significance of islands is also considered. The final two chapters are devoted to habitat fragmentation, both on the scale of mountain ranges and at the nature reserve level.

The bibliography for this topic is, not surprisingly, considerably smaller than that for vegetation dynamics. The editors should have insisted upon a uniformity of arrangement of references which, in this book, are placed at the end of chapters.

This new series has commenced with two useful and readable booklets and subsequent titles must be awaited in hopeful anticipation. Some of the future authors, we gather, will derive from areas other than eastern Scotland; the home team has set them a high standard to maintain. ☐

P.D. Moore is Senior Lecturer in the Department of Plant Sciences at King's College, University of London, UK.

Microbial ecology

P. S. Meadows

Microbial Ecology: A Conceptual Approach. Edited by J.M. Lynch and N.J. Poole. (Blackwell Scientific: Oxford, 1979.) Hardback £19.50; paperback £9.80.

THIS book is a mixture of styles and subjects, and standards — some of them excellent, a few mediocre and one or two very poor. The book is divided into three major sections on (1) the principles of microbial behaviour in ecosystems, (2) microorganisms in their natural environments, and (3) economic microbial ecology.

Much of the first of these is interesting reading, although I am not convinced of the need for a detailed description of the range of microorganisms (chapter 2.1). The mathematical treatment of population and community dynamics in chapter 2.3 is not easy to follow unless one has a good grasp of mathematics. It could have been presented in a simpler way without loss of much detail.

The second section contains the main part of the book with six chapters. Chapters on the terrestrial and aquatic environment are followed by the animal as an environment, extreme environments, aerial dispersal and biological interactions. Parts of these are well presented and interesting; but there are some omissions and a few inadequacies. Much of the chapter on the aquatic environment is to my mind too general, and is not strictly related to microbial ecology except in a very broad sense. For example, the large diagram on the major oceanic gyres is not really necessary. Biological interactions (chapter 3.6) contains two pages on the rumen and caecum (a field that would not be regarded as ecological by some ecological purists), whereas the relationships between microorganisms and invertebrates in sediments and on solid surfaces in aquatic environments receives hardly any comment.

The last major section — on economic microbial ecology — has one first-rate chapter on nitrogen fixation, two chapters of variable standard on microbial spoilage of food and on water pollution, and one quite extraordinary one on recalcitrant molecules.

The book has excellent parts to it.

However, I have three major criticisms. The first stems from the book being a compilation of chapters by different authors. This has led to fragmentation, but not to an unacceptable degree. The second is more serious. Some of the diagrams are impossible to understand except after long contemplation (Figs 3.2.6, 3.2.17, 3.5.8, 3.5.12), which is a pity because some are models of clarity (Figs 2.2.12, 3.2.15). The third criticism is one about writing English. Parts of the book are badly written and this can only reflect on the authors. The introduction and epilogue and especially the chapter on recalcitrant molecules should not have been published in their present form. They are often long-winded, difficult to understand, and grammatically wrong.

All of this is a pity because many other parts of the book are very readable and interesting. □

P. S. Meadows is a Senior Lecturer in Zoology at the University of Glasgow, UK.

Microbial physiology and nitrogen fixation

C.F. Thurston

Bacterial Metabolism. By G. Gottschalk. Pp.281. (Springer: New York, Heidelberg and Berlin, 1979.) $23.00. *The Biology of Nitrogen-fixing Organisms.* By J.I. Sprent. Pp.196. (McGraw-Hill: Maidenhead, UK, 1979.) £5.50. *Microbial Physiology.* By A.G. Moat. Pp.600. (Wiley: New York and Chichester, UK, 1979.) £16.95.

THESE books provide an intriguing study of the different approaches that can be taken when writing for students. All three are concerned more or less with metabolic processes of microorganisms, but there is little else in which they are similar.

Bacterial Metabolism, by G. Gottschalk, is accurately described by its title. It is about the biochemical transformations achieved by prokaryotic organisms and in my opinion is the best concise treatment of the subject available. The text is clear and well illustrated with metabolic schemes and much tabulated information. It starts with a chapter on bacterial nutritional requirements and types which is followed by two large chapters: "How *Escherichia coli* synthesises ATP during aerobic growth on glucose" and "Biosynthesis of *Escherichia coli* cells from glucose". These chapters set a framework which is built on in subsequent chapters to form a very complete picture of bacterial metabolic activity, showing the variations exploited when different substrates for growth are used and/or when different organisms are involved. For instance, the descriptions of catabolic activities of aerobic heterotrophs and of chemolithotropic modes of metabolism are more thorough and detailed than in any other comparable student text book I have seen. Of the topics included, protein biosynthesis has the least generous coverage; but as this is so well described in many modern textbooks of molecular biology and/or general biochemistry its coverage here is sufficient. All chapters have an informative summary and there is a list of titles for further reading, and subject indexes. The last chapter concerns the fixation of molecular nitrogen, which is dealt with from a biochemical standpoint, consistent with the rest of the contents of this readable and informative book.

Nitrogen fixation in the broader context is the subject of *The Biology of Nitrogen-fixing Organisms*, by J.I. Sprent. The very wide range of prokaryotes which are able to fix gaseous nitrogen are described with something of their classification. This is integrated with descriptions of the other organisms with which many nitrogen fixers are involved in elaborate symbiotic relationships, although in the case of nitrogen-fixing lichens this treatment is brief. The second chapter examines the biochemistry of nitrogen fixation, including properties of nitrogenase, sources of energy and reductant and some mechanisms which allow nitrogen fixers to reduce or prevent the oxygen inhibition to which nitrogenases are very sensitive. This chapter is not always easy to follow and is illustrated with diagrams which lack clarity, for instance in Figs 2, 3, which show the photosynthetic electron transport chain of *Anabaena*, it is obscure as to where reducing equivalents originate. I was also most disappointed that there was no inclusion of the genetics of nitrogen fixation. The conventional genetic analysis of the *nif* genes of *Klebsiella pneumoniae* and the more recent studies using the techniques of 'genetic engineering' at Sussex and Harvard have contributed much towards the understanding of nitrogen fixation and for many people (whether rightly or wrongly) suggest a possible way for dramatically improving the productivity of world agriculture. I think it was wrong to omit this work altogether.

The following three chapters discuss nitrogen fixation in relation to agriculture, forestry and natural ecosystems. They are an absorbing account of research in plant physiology and experimental ecology presenting much original data showing the importance of fixation to the nitrogen economy of different ecosystems, and the considerable challenge presented to biologists wanting to understand what limits the quantity of nitrogen fixed in the field and what might increase the amount of fixation. The final chapter describes possible evolutionary relationships of nitrogen-fixing organisms and is followed by an informative appendix describing methods of measuring nitrogen fixation. The text is well supported with references, as many as 100 for some chapters.

Microbial Physiology, by A.G. Moat, also uses specific references throughout the text which are listed at the end of each chapter, but otherwise it has little similarity with Dr Sprent's book. According to its dust cover the book draws together the current knowledge of the fine structure (cell structure, substructure), metabolism, and genetics of microorganisms and describes the interaction of these physiological activities in the growth of microbial cells. . ." I find this approach to what constitutes the physiological activities of microorganisms curious and I am confident that others will be equally surprised to find the first 120 pages of a book with this title devoted to classification and cell structure. From Professor Moat's preface it emerges that this is substantially a course book for his students and reflects an interesting and broad ranging course in general microbiology, albeit with a physiological emphasis. It is also directed particularly at "students who will ultimately choose to work outside the immediate realm of microbial physiology". I think other microbiology teachers may find the choice of material and the relative depth of coverage not well suited for their students.

The book is well illustrated and contains a lot of detailed useful information, but classification, cell structure, microbial genetics and morphogenesis together occupy over a third of the text. Consequently, I feel it is unfortunate in a book of this size and price that some truly physiological topics are omitted and others are given relatively scant attention. For instance, growth is the subject of one chapter, but the relationship between limiting-nutrient concentration and growth rate is not described; continuous (chemostat) culture is mentioned only twice, in passing, is not defined and is illustrated by a schematic diagram (Fig. 9-5) where the growth chamber contents would regularly siphon out — it is in fact a recycling fed-batch culture apparatus! Parameters such as growth yield and maintenance energy are not mentioned and macromolecular turnover gets little attention. There are substantial chapters on carbohydrate metabolism and energy production, on nitrogen metabolism and on amino acids, purines and pyrimidines, but I was unable to find a description of any mechanism for nutrient uptake or how such a process may be driven at the expense of metabolic energy. I think I can accept that a course in microbial physiology does not have to include the *lac* operon of *E. coli* as an example; but I deplore the absence from a textbook of the subject, of any description of the control system of a well studied inducible operon, such as *lac, ara, gal* or *hut*. I was also surprised to find only occasional mention of catabolite repression, with in one instance, a hint that this might be a cyclic-AMP mediated phenomenon; indeed the unqualified and unsupported statement that "the enzymes of the glyoxylate bypass are repressed . . . by a process known as catabolite repression" infers a broader definition of this phenomenon than I have encountered elsewhere. Another area of confusion concerns the assimilation of carbon dioxide by phototrophic microorganisms. First, the text states "Photoautotrophs . . . fix carbon dioxide via either the reductive pentose phosphate (Calvin–Benson) pathway or the reductive C_4-dicarboxylic acid (Hatch–Slack) pathway. These systems were first discovered in green plants". I would infer that the unicellular green alga *Chlorella* (with which Calvin's group worked) is regarded by the author as a green plant and not a microorganism, were *Chlorella* not specifically mentioned as a group of organisms included in the eukaryotic protists (page 12). Second, Fig. 3-21 entitled "The reductive C_4-carboxylic acid (Hatch–Slack) cycle" is actually the reductive (or reverse) tricarboxylic acid cycle proposed by Evans, Buchanan and Arnon, which is dependent on two ferredoxin-catalysed carboxylation reactions characteristic of anaerobic metabolic systems and which are not present in the higher plants which show the C_4 pattern of assimilation investigated by Hatch and Slack. Indeed the role of phosphopyruvate as a product of CO_2 fixation in the reverse TCA cycle contrasts strongly with CO_2 fixation by C_4 plants where phosphopyruvate is generally considered to be the co-substrate for the key carboxylation reaction.

The reader will by now conclude rightly that I would not recommend A.G. Moat's book, and there are several general microbiology texts I would prefer.

Returning briefly to the other two volumes discussed I am pleased to have read them, I shall return to them again and I think they both represent good monetary value. *The Biology of Nitrogen-fixing Organisms* has an engaging scholarly style and I am sure will be widely read by biology students and others. Gottschalk's *Bacterial Metabolism* is excellent and I will be surprised if it is not extremely popular amongst students and teachers of microbiology and biochemistry for a very long time. □

C.F. Thurston is a Lecturer in the Department of Microbiology at Queen Elizabeth College, London, UK.

Microorganisms in their environment

J.P. Armitage

Microorganisms: Form, Function and Environment. Edited by L.E. Hawker and A.H. Linton. Second edition. Pp.391. (Edward Arnold: London, 1979.) Paperback £8.95.

THE second edition of this undergraduate textbook has changed format. It is now a fashionable large size book with large, bold print and diagrams. Its sixteen chapters, with twenty-two authors (all, except one, from the University of Bristol), have been divided into three sections: biochemistry and physiology, form, size and life cycles of microorganisms, and the activities of microorganisms in their environment.

The strength of the first edition lay in the good mix of prokaryotic and eukaryotic microbiology and the emphasis on their behaviour in the environment. To this end this edition has added an excellent new chapter on symbiotic interactions.

However, the new format has resulted in many fewer words than the first edition and, rather than keeping or expanding the better areas of the first edition, all sections have been reduced. This results in much weaker coverage of many areas, in particular biochemistry.

The editing has also been hit and miss: for example, *Klebsiella pneumoniae* is referred to as *K. aerogenes* in the first section, but by its correct name in the second; *Rhodospirillum* has been misspelt and page references to other parts of the book have been left incomplete.

The difficulty with all multi-author textbooks is keeping the level and theme consistent. Unfortunately, by reducing the size of this book but attempting to retain all the subject matter of the first edition the result is a weaker textbook with little to recommend it over the other general textbooks on the market. □

J.P. Armitage is a Postdoctoral Research Scientist in Microbiology in the Department of Botany and Microbiology, University College London, UK.

Soil properties

Stephen Nortcliff

Geography and Soil Properties. By A.F. Pitty. Pp.287. (Methuen & Co Ltd: Andover, 1979.) Hardback £10; paperback £5.50. *Soil Erosion.* By R.P.C. Morgan. Pp.113. (Longman: Harlow, UK, 1979.) Paperback £3.95.

NOTWITHSTANDING the title of this text, the major shortfall of the first book is a failure to place the wealth of information on soil properties into a geographical context. The opening chapter presents a wide ranging review of soils and geography, both physical and human, together with a brief comment on soils and geographical method. In subsequent chapters little attention is paid to geography; rather, the emphasis is placed on detailed descriptions of numerous soil properties.

Although the detailed information presented together with an extensive bibliography of over 40 pages is evidence of considerable effort in compilation, frequently much of the information is presented without a context; also it is not shown why so much detail is important to the geographer. At times less information coupled with more elaboration and discussion would have produced a more complete and easily readable text more suitable for undergraduate use.

The second book is one of a series of short texts in applied geography suitable for undergraduates studying in the fields of environmental sciences, geography or geology. In a little over one hundred pages the author has set himself the task of making the reader aware of the importance of soil erosion as a problem throughout the world, the mechanics and processes of soil erosion, the factors which influence soil erosion, soil conservation practices and the scope for modelling soil erosion studies, as well as giving some examples of soil erosion studies.

Remarkably the author achieves this, but only by presenting the reader with just a brief outline of each topic. Any additional information must be added by the reader, and to this end there is a bibliography chiefly of erosion studies. As an undergraduate text this approach may be acceptable, but at times a little elaboration or development of the topic would have greatly improved the text. In the introduction the author stresses that although soil erosion has long been acknowledged as a problem in tropical and semi-arid areas, it is increasingly recognised as a hazard in temperate countries. It is a pity that few of the examples used refer to erosion in these temperate countries. □

Stephen Nortcliff is Lecturer in Soil Science at the University of Reading, with teaching responsibilities in pedology and soil management.

Plant systematics and taxonomy

V.H. Heywood

Plant Classification. By L. Benson. Second edition. Pp.901. (D.C. Heath and Company: Lexington, Massachusetts and Toronto, 1979.)

In the 22 years that have elapsed since the publication of the first edition of this work, plant systematics and taxonomy have experienced major changes, but these are scarcely reflected in this new edition. It is intended as an elementary textbook "to open up the new world of living plants to college students and the educated public". The author refers readers to his *Plant Taxonomy, Methods and Principles* (Ronald: New York, 1962, 1978) for an advanced treatise covering the application of cytogenetic and experimental investigations to plant taxonomy.

On the other hand, new information and ideas on the origin and relationships of the major groups of vascular plants other than the flowering plants are taken into account in the appropriate sections of this edition. For the flowering plants, four new systems of classification, namely those of Stebbins, Takhtajan, Cronquist and Thorne, are considered (chapter 16), though not fully accepted; and the author has presented a revised version of his own system, the most conspicuous change being the final abandonment of the Amentiferae as a partly natural, partly artificial group. No mention is made of other recent systems such as those of Dahlgren and Soó. The section of the book devoted to the classification of natural floras, primarily with reference to North America, has also been revised.

Overall, this new edition of Benson's major work retains the merits and faults of the original. It is too long (nearly 900 pages) and diffuse and covers too many diverse topics for a single work. It is an excellent book to dip into, but is scarcely likely to recommend itself to students outside North America as a textbook of systematics, although it contains a large amount of information that would be useful for various courses. The book is well printed and illustrated, but the binding in my review copy has already come adrift. □

V.H. Heywood is Professor and Head of the Department of Botany, University of Reading, UK, and currently Dean of the Faculty of Science.

Fungal biology

P.E. Long

Biology of the Fungi: Their Development, Regulation and Associations. By Ian K. Ross. Pp.499. (McGraw-Hill: New York and London, 1979.) £11.20.

Professor Ross sets out to provide an introductory undergraduate text emphasising developmental and regulatory aspects and has succeeded by presenting, in a conversational style, a lively, questioning and personal account both of the fungi and of the protistan mycetozoa and their allies traditionally studied by mycologists. Some will find, as the author anticipates, that treatments of particular groups or topics offend their susceptibilities but a reasonable balance and wide coverage have been achieved in the three sections that deal with the salient features and developmental pathways of the organisms under consideration; discuss the regulation of their vegetative and reproductive development; and review their associations. The latter, shortest section includes a welcome chapter on viruses in fungi but is really a rather loose mixture, strictly fungal, additionally ranging from their spore liberation and dispersal through saprobic, mutualistic, parasitic and predatory activities to their impact on human affairs.

My initial enthusiasm became tempered by the impression that the survival strategies of the septate higher fungi and their capacity to produce varied multihypal structures are not sufficiently described. Furthermore the roles of vacuolation and septal pore occlusion in thallus development are neglected as is much experimental work both on conidiation and the cell cycle in yeasts, while hyphal wall architecture and synthesis receive rather cursory attention. To be fair many of these deficiencies can be rectified by diligent use of the extensive bibliography although this remedy is not available for readers of chapters 15 and 16, as, atypically for this up-to-date textbook, few post-1970 books on parasitism or mutualism are cited. Some more generally useful sources are overlooked too, including Ainsworth and Bisby's *Dictionary of the Fungi* (Sixth edition, Commonwealth Mycological Institute, 1971). The figures, mainly in the first section, are good but many lack any indication of scale and some captions are so terse as to be uninformative. Hopefully the appellation 'death cup' that appears under Figure 6.36 will not become perpetuated.

These expressions of vexation denote my exasperation at points which diminished the appeal of a stimulating and attractive book that provides many ideas and much material for a modern course in mycology. The approach is fresh, the arguments enjoyable and some topics are new in a text which will be particularly useful to students who have had some previous exposure to university level cell biology, while also providing food for thought to their instructors. □

P.E. Long is a Lecturer in Mycology in the Department of Botany at the University of Leicester, UK.

Introductory soil science

D.L. Rowell

Introduction to the Principles and Practice of Soil Science. By R.E. White. Pp.198. (Blackwell Scientific: Oxford, 1979.) £8.50.

Although there have been several books published recently which deal with soils from a geographical viewpoint, this is the first book of its kind to appear for many years. It is a valuable attempt to present soil science at an introductory level, and has successfully shown how biology, chemistry and physics are integrated in the study of this part of our environment. It is thoroughly up to date, including for the first time at this level much that has been understood only recently.

The first two sections deal with the principles of soil science and the third part looks at the application of these principles to soil management, primarily from an agricultural point of view. The book is suitable for use in a wide range of courses at universities, technical and agricultural colleges. It assumes O level knowledge of the sciences, but occasionally starts at a higher level — surely a mistake for a book of this sort. Material is presented very effectively in diagrammatic form. The text is sometimes very concise, perhaps making it difficult for the book to be used in isolation from taught courses. □

D.L. Rowell is Lecturer responsible for the teaching of introductory soil science courses in the Department of Soil Science at the University of Reading, UK.

How plants work

James Sutcliffe

Plant Physiology. By R. G. S. Bidwell. Second edition. Pp.726. (Collier-Macmillan: London and Basingstoke; Macmillan: New York, 1979.) £14.25; $18.95 in USA. *Organization in Plants.* By W. M. M. Baron. Third edition. Pp.264. (Edward Arnold: London; University Park Press: Baltimore, 1979.) Paperback £6.75.*Physiology of Woody Plants.* By P. J. Kramer and T.T. Kozlowski. Pp.811. (Academic: New York and London, 1979.) $35; £22.75. *Plant Metabolism.* By G. Richter. Pp.475. (Croom Helm: London, 1979.) £11.95. *Plant Metabolism.* By H. D. Kumar and H. N. Singh. Pp.302. (Macmillan: London and Basingstoke, 1979) Paperback £4.95. *The Control of Growth and Differentiation in Plants.* By P. F. Wareing and I. D. J. Phillips. Second edition. Pp.347. (Pergamon: Oxford, 1979.) Hardback £15; paperback £7. *Water Flow in Plants.* By J. A. Milburn. Pp.225. (Longman: London and New York, 1979.) Paperback £6.75.

FOR those of my generation who studied plant physiology during and immediately after the second World War choice of textbooks was extremely limited. Now the situation has changed dramatically and students in the 1980s have a wide range of attractive texts some of the more successful of which have recently appeared in new editions. Comparison of a lavishly illustrated modern textbook such as Bidwell's *Plant Physiology* with those that were available to me in the 1940s shows how much the standards of book production have improved in the intervening years.

A popular successor to James' *An Introduction to Plant Physiology* as an introductory text is Baron's *Organization in Plants.* First published in 1963 the book has been extensively revised for the third edition. Like his predecessor, Baron places great emphasis on the encouragement of practical work and it is good to see graphs summarising data obtained in class experiments illustrating the text. An appendix gives details of a number of experimental procedures which should be well within the scope of most school laboratories, and a useful starting point for student projects. Some advice about the design of experiments and simple statistical procedures for the analysis of results would be a welcome addition to this section. A new chemical nomenclature, which I assume is now being taught in schools, is used throughout the book. I suppose that we shall all get used to it in time, but is it really wise to call acetaldehyde ethanal which can be so easily confused with ethanol, however logical it might seem to be? It is something of a relief to be informed that acetic acid for some unexplained reason is still acceptable to the powers that be.

Nowadays a problem for writers of plant physiology textbooks is the lack of general botanical knowledge among their readers because the teaching of traditional botany in schools has almost ceased. To overcome this, Baron provides some background information about the structure of plant cells, but for vital details of plant anatomy the student must go elsewhere. It is a pity that the list of books for further reading at the end of chapter 1 does not include a textbook of general anatomy.

Bidwell's *Plant Physiology,* the first edition of which appeared in 1974, is one of several excellent textbooks by North American authors which give comprehensive coverage of the whole field of plant physiology at a fairly advanced level. Although like most other contemporary texts it concentrates mainly on the physiology of flowering plants with particular reference to those crop plants which have been studied intensively, there is a section devoted to the physiology of what are described as "special" organisms. These include trees, as one might expect from a Canadian-based author, macroscopic algae, parasites and symbionts. In keeping with modern trends space is found for such topics as the effects of stress on plant growth and the influence of man on his environment.

Students who wish to learn more about the physiology of trees should turn to Kramer and Kozlowski's *Physiology of Woody Plants.* This book is an amalgamation and up-dating of two earlier books by the same authors. It is written primarily for foresters and arborists but inevitably it contains a good deal of general physiology. Biochemical topics are reviewed rather briefly and the book concentrates on more physiological and ecological aspects of plant physiology. There are useful chapters on the structure of wood and the characteristics of tree growth. A final chapter is concerned with the influence of environmental factors and cultural procedures on the productivity of forests and orchard crops. The text is supported by a large amount of experimental data and in addition to a substantial list of general references at the end of each chapter there is a bibliography of some 2,200 titles.

Plant biochemistry has been the subject of several new textbooks recently, among them Gerhard Richer's *Plant Metabolism.* This is an English (Americanised) translation of an apparently successful German textbook, *Stoffwechsel Physiologie der Pflanzen,* which was first published in 1969. Although the text has been revised for the English edition the more recent references quoted are to papers published in 1973 so that in certain areas of this rapidly advancing field the book is already somewhat out-of-date. More than a third of the volume is taken up by an account of photosynthesis which is well presented with the help of clear informative diagrams. The remainder of the book deals with such topics as respiration, the biosynthesis of cellular components and metabolic regulation in a straightforward and fairly conventional manner. No attempt is made to relate metabolic processes to growth but there is a brief incursion into plant water and ion relations and a section is devoted to the role of anions and cations in metabolism.

Extensive use is made of small print when describing experimental procedures and historical aspects of the subject. This enables the author to get much more information into a book of modest dimensions than would otherwise have been possible. However, this and the liberal use of italics throughout the text give the book a rather outdated look which I do not feel will appeal to American readers for whom it is apparently intended.

At less than half the cost of Richter's book one may obtain Kumar and Singh's *Plant Metabolism* which covers very similar ground at about the same level. The new edition of a book which was first published in India in 1976 has been printed there and does not reach the high standard of book production that we have come to expect from the publishers. Again quite a large part of the text is concerned with photosynthesis and as both authors have worked on unicellular algae it is not surprising that algal research features prominently in their account; but there is an adequate treatment of the various pathways of carbon assimilation in higher plants too. The rest of the book is less than inspired, being in the main a rather pedestrian account of the metabolism of nitrogen and sulphur, nucleic acids, proteins, lipids and secondary plant products. In the preface, the authors urge their readers to consult original papers but they provide very little incentive by failing to capture in their writing much of the excitement of biochemical research. Their rather unselective suggestions for further reading including, for example, several outdated textbooks and reviews, are not particularly helpful.

A large part of plant physiology is concerned with the processes of growth and development and there are several textbooks devoted entirely to this subject. One of the most popular of these in recent years has been Wareing and Phillips' *The Control of Growth and Differentiation in Plants* which was first published in 1970. The book is mainly concerned with the effects of plant growth regulating substances on various facets of plant growth. In the second edition the material has been re-organised and parts of the text have been revised in the light of developments in the intervening years. A comparison of the two editions indicates that apart from advances in understanding of the role of phytochrome in photomorphogenesis, which now merits a separate chapter, and the control of flowering there have been no outstanding discoveries in this field during the 1970's. It must have been somewhat depressing for the authors to find that so many of their pious hopes of advances expressed in 1970 remain unfulfilled in 1978. I think that in the second edition I would have felt inclined to alter the form of words a little and explain why certain problems have remained surprisingly intractable. The picture is not perhaps quite so black as Wareing and Phillips have made it appear because they do less than justice to the not-inconsiderable advances that have been made in the intervening years in knowledge of control mechanisms at the enzyme level. Fortunately there are other books which remedy this deficiency.

One of the most difficult subjects to put over to students of plant physiology is water relations. Teaching this subject is not helped by the less than adequate treatment of it in many textbooks. Authors of such books would do well to read Milburn's stimulating book on *Water Flow in Plants* before revising this section of their works. Milburn begins by describing the properties of water and he gives a clear account of the concept of water potential before going on to describe various kinds of apparatus by means of which water movement can be studied. He then describes the water relations of cells and traces the pathways of movement through the soil-plant-air continuum. There is an interesting chapter on responses to water stress and a description of a new device "the oil bomb" which may prove helpful for studying effects of stress on growth.

There is a useful set of appendices containing lists of symbols, units, physical data etc., and a series of numerical problems which will exercise the minds of some university teachers and tutors as well as their students. ☐

James Sutcliffe is Professor of Plant Physiology in the University of Sussex, Brighton, UK.

Vegetation productivity

Melvin G.R. Cannell

Vegetation Productivity. By G. Jones. Pp.100. (Longman: Harlow, UK, 1979.) Paperback £3.95.

THIS little book is an attempt by a geographer to introduce people without any knowledge of plant science to the subject of vegetation productivity in different environments and the ways in which that productivity can be measured. The book is easy to read and may satisfy geography students, but it adds nothing to the books already available on this subject.

Chapter 1 is a introduction to plant physiology, misleadingly entitled "The measurement of plant growth". None of the concepts of plant community productivity are discussed, and photosynthesis itself gets only a brief mention. Chapters 2 and 3 on vegetation productivity contain useful reviews, but readers wanting accurate, balanced and more comprehensive accounts will need to refer to Cooper's book (*Photosynthesis and Productivity in Different Environments.* International Biological Programme 3, Cambridge University Press, 1975) which is not mentioned. Also, anyone seriously interested in measuring forest or grassland productivities will need the handbooks prepared by Newbould (*Methods for Estimating the Primary Production of Forests.* International Biological Programme, Handbook No. 2, Blackwell: Oxford, 1967) and Milner and Hughes (*Methods for the Measurement of Primary Production of Grassland.* International Biological Programme Handbook No. 6, Blackwell: Oxford, 1968) which form the bases of chapters 4 and 6, respectively. Chapter 5 describes the author's work on forest growth in relation to soils, and chapter 7 offers some conclusions.

It is a pity that this book was not co-authored or edited by a plant scientist: vegetation is said to "produce" calories (page 14), transpiration is confused with respiration (page 19), a linear regression is said to follow a curve (page 55), and so on. Many figures and tables are poorly explained and both metric and imperial units are used. Furthermore, the thesis of the book, that a natural plant community provides a measure of the upper limit of vegetation productivity in a given environment, is, at best, highly contentious. ☐

Melvin G.R. Cannell is Principal Scientific Officer and Tree Crop Physiologist at the Institute of Terrestrial Ecology, Penicuik, UK.

Plant diseases

I.M. Smith

Epidemiology and Plant Disease Management. By J.C. Zadoks and R.D. Schein. Pp.427. (Oxford University Press: Oxford and New York, 1979.) £13.50.
Atlas and Manual of Plant Pathology. By E.H. Barnes. Pp.325. (Plenum: New York and London, 1979.) £12.35.

IT is a pleasure to welcome Zadoks' and Schein's textbook. Plant disease epidemiology has developed enormously in theory and practice in the last twenty years, and the ideas of management in plant protection are spreading from pests to diseases. No university plant pathology course can now fail to tackle these new developments. This new text, though possibly not quite a primer for students with only basic knowledge, provides an excellent introduction to the subject for advanced students. As the authors suggest, the student can choose to benefit from any of the attractive self-contained chapters. They will at all times find clarity of exposition and an interesting and engaging style.

The work builds from the basic level of single infection cycles (monocyclic processes), through population phenomena (polycyclic processes), to the whole pathosystem and its management. It builds from the basic methods of disease control to their integration, from the familiar to the less familiar. It is realistic and critical, and pleasantly free from mysterious jargon.

The core chapter on the essential concepts of epidemiology and their mathematical background is clearly developed and well illustrated, presenting few problems to the not very mathematical reader. There is an excellent chapter on disease and crop loss assessment. Chapters on "Ecological concepts in plant pathology" and "Matters of scale" bridge the sections, the former providing useful comparisons with general ecological concepts.

The text does not make any attempt to deal with the techniques or apparatus of epidemiology, which are perhaps somewhat beyond its scope. However, practical considerations are well in evidence, especially in the assessment chapter, and a most useful feature is the inclusion of simple argued examples from the literature. Many chapters conclude with a useful set of exercises. In conclusion, this is an excellent reasonably priced textbook which will certainly find very wide use in advanced courses in plant pathology for years to come.

The *Atlas and Manual of Plant Pathology* is, by comparison, not a work of any outstanding interest. A republication of a 1968 edition, with minor modifications, it treats a series of diseases on a taxonomic basis, giving general information on each (causal organism, symptoms, control), together with black and white photographs at macroscopic, hand-lens and microscopic levels. The descriptions are sometimes supplemented by details of laboratory experiments, which are possibly the most interesting part of the work and have not especially dated since the first edition. However, epidemiology receives little attention. The numerous photographs are certainly useful for the systematic study of plant diseases, However, with a certain prejudice against prepared slides, the present reviewer regrets the non-inclusion of any instructions on how to examine fresh or cleared material. At the other end of the scale, a modern text should surely show some of the insights given by electron microscopy.

The text is also regrettably out of date, and indeed misleading in many respects. Nomenclature is sometimes outdated and recent developments bypassed (crown gall). Most unfortunate perhaps is the very old-fashioned section on plant virology. The point is that, in this and many other respects, plant pathologists can be quite proud of the progress made in the last decade. It is a pity, therefore, to republish an old textbook, without taking the trouble to revise it. ☐

I.M. Smith is Deputy Director-General of the European and Mediterranean Plant Protection Organization, Paris, France.

Plant breeding

Barbara Pickersgill

Principles of Crop Improvement. By N.W. Simmonds. Pp.408. (Longman: Harlow, UK, 1979.) £7.95.

THIS is the first new textbook on plant breeding for about 12 years, but a decade is a short time to a breeder so the subject matter discussed remains basically unaltered. Where this book differs from its predecessors is in its excellent treatment of conservation of genetic resources and the green revolution and, more particularly, in its uncompromisingly practical orientation.

Background information on crop evolution, population genetics, polygenic inheritance and heritability is used to discuss the breeder's very real problems of breeding strategy, selection, scale of operations and profitability in either social or real terms. Academically elegant special cases such as aneuploidy in barley or regulation of recombination in wheat breeding get little mention. Indeed, cytology takes a back seat throughout. Tropical crops provide about as many examples as temperate crops, which should increase this textbook's appeal to those teaching in developing countries.

Professor Simmonds writes clearly and concisely but two stylistic traits detract slightly from the book's readability. One is the intentional use of very long captions to tables or figures. By the time one has assimilated those, one tends to have lost the drift of the textual exposition the table or figure was to illustrate. The other is the use of abbreviations. Sentences such as "Thus, summarising the slightly confusing nomenclature of OPP breeding, we have: PIM (varieties propagable as such) contrasted with SYN (varieties regularly reconstructed from parents), with the former based on either MSL or PRT" may completely baffle students who find even basic genetic terminology difficult. Unfortunately there is no glossary, nor are abbreviations listed as such in the index.

Numerous thought-provoking examples for the reader to work are embedded in the text or captions and carry the textual argument further. It is therefore advisable to do one's homework thoroughly before assigning class reading in this book.

On price, this text compares favourably with most of its competitors. It seems likely to achieve its author's hope of providing a broad general introduction to plant breeding as an intensely practical art. ☐

Barbara Pickersgill is Lecturer in the Department of Agricultural Botany at the University of Reading, UK.

The natural selection

M.J. Lawrence

Introduction to Evolution. By F.A. Racle. Pp.161. (Prentice-Hall International: Hemel Hempstead, UK, 1979.) £5.80. *The Biological Environment.* Edited by J. Lenihan and W.W. Fletcher. Pp.164. (Blackie: Glasgow and London, 1979.) Hardback £9.95; paperback £4.95. *Evolution.* By C. Patterson. Pp.197. (British Museum (Natural History)/ Cornell University Press: London, 1979.) Hardback £5.95; paperback £2.95. *Evolving: The Theory and Process of Organic Evolution.* By F.J. Ayala and J.W. Valentine. Pp.452. (Benjamin/ Cummings: Menlo Park, California, 1979.) $16.95. *An Introduction to Evolutionary Genetics.* By D.T. Parkin. Pp.220. (Edward Arnold: London, 1979.) Paperback £6.50. *Evolution.* Readings from Scientific American. Pp.135. (Freedman: San Francisco and Reading, UK, 1979.) Hardback £7; paperback £3.20. *Ecological Genetics.* By E.B. Ford. Pp.442. (Chapman and Hall: London, 1979.) Paperback £7.50.

THIS is a very mixed batch of books which vary greatly in the breadth and depth of their treatment of evolution and related subjects, in their intended readership and in their length. Some, having been written for the layman, assume no previous knowledge of the subject, while others require at least a knowledge of elementary genetics and biology and are, therefore, of a more specialised interest.

Racle's book, though one of the shortest, attempts to cover the full range of evolutionary studies. Because it is intended for undergraduate non-science majors in American universities and colleges, it contains chapters on elementary geology, which is treated in an historical fashion, and Mendelian genetics. The chapter on population genetics is the least satisfactory not least because it is not at once made clear that the Hardy–Weinberg equilibrium applies only to a population of randomly mating individuals. Discussion of the sickle-cell polymorphism would also have been better done in this chapter rather than in the preceding one dealing with Mendelian genetics. The rest of the book treats the subject in an orthodox fashion and there are chapters on the evidence for evolution and natural selection, on the origin of life, phylogenetic divergence in the plant and animal kingdom, and two chapters on human evolution, though surprisingly, there is little about molecular evolution. The wide coverage of the subject in this short book, which is written in a pleasantly undemanding style, would make it suitable for use in schools.

Lenihan and Fletcher's book is the ninth volume in a series on *Environment and Man* and is intended for "practitioners and students in science, engineering, medicine, administration and planning". It is a rather odd and uneven book with few illustrations or diagrams. The chapters by Fletcher on "Evolution and the Natural Environment", by Ainsworth Harrison on

"Human Evolution and the Environment", by Lenihan on "Is Man a Machine?" and by Smith on "Microbes and the Environment" are straightforward and well written. Jeffers' chapter on "Conservation of the Biological Environment" is authoritative and full of relevant information, though perhaps a little less easy to read than the others. Forbes Robertson's chapter on "Natural Selection in Man" is far too demanding for the intended readership and is, frankly, rather dull. I also have some doubts about the wisdom of attempting to produce a series of books that is aimed at such a wide, semi-professional readership, though with some guidance, this particular volume could also be used in schools.

Patterson's book is a very well written, lucid and up-to-date account of the subject, which ranges from molecular biology to the philosophy of science. Though a short book, it contains numerous excellent illustrations, one of which, on Batesian mimicry in butterflies, is in high-quality colour. The fate of new mutations in a population is particularly well handled. It is to be regretted, however, that the explanation of the concept of fitness is done in terms of gametic rather than the more usual zygotic genotypes (page 58). Fortunately, this has no unfortunate consequences because thereafter the author very sensibly deals with changes in gene frequency in the population in purely verbal terms. Though the book is intended for the layman, its excellence is such that it would be suitable for use both in the sixth form and in the early years of undergraduate courses in biology in universities.

As one would expect from a pair of experienced authors and researchers in the field, Ayala and Valentine's book is a very broad, competent, well illustrated and up-to-date treatment of evolutionary ideas and studies, which, like Racle's book, has been written with the collegiate layman in mind. However, because of its length, the authors are able to deal with the subject in much greater depth than in any of the preceding books. For this reason, the book would serve as an excellent introduction to the subject for the non-specialist undergraduate biologist also. Any teacher recommending the book for this purpose, however, would be obliged to point out a quite unforgivable error in diagrams on pages 31 and 32 which show that the chromosomes are double structures in the early stages of the first division of meiosis, whereas, of course, they are in fact single until late in the pachytene stage. This is such a serious error that it ought to be corrected by an erratum slip at least before any further copies of the book are sold.

Parkin's book has been written for undergraduate students in the biological sciences and assumes, therefore, some knowledge of Mendelian and cytogenetics. Unfortunately, it is a rather uneven book. The first chapter on evolution by natural selection, which gives a sketch of the historical background, is nicely written as are some parts of most of the following chapters. In far too many places, however, the point that the author is trying to make is not very clear, which is partly a consequence of his having included too many poorly digested examples. There are also a number of errors. For example, the probability of fixation of a neutral mutant is $1/2N$, not $1/2N_e$ (page 34); East and Mangelsdorf, rather than Emerson, were the first to describe the genetics of self-incompatibility in the system found in *Oenothera organensis* (page 103); and heritability is not the proportion of the genetic variance that is due to additive genetic variance (page 114). In addition, several of the figures are either hard to understand or hard to relate to the text (for example, Figs 6.3, 6.5, 7.6 and 8.7). There are also more than a small number of misprints and typographical errors. It is a great pity that the book is marred by these errors for it would otherwise be a useful addition to the literature on evolutionary genetics at this level.

The nine chapters in the *Scientific American* book, which originally appeared in the September 1978 number of this journal, cover the full range of the subject from chemical evolution and the origin of life (Dickerson) to the evolution of man (Washburn). There is an introduction by Mayr and the remaining chapters are by Ayala on "The Mechanism of Evolution", by Schopf on "The Evolution of the Earliest Cells", by Valentine on "The Evolution of Multicellular Plants and Animals", by May on "The Evolution of Ecological Systems", by Maynard Smith on "The Evolution of Behaviour" and by Lewontin on "Adaptation". Though the articles have presumably been written with the layman in mind, their authority and the excellence of their illustrations are such that they are, in my view, a better introduction to modern ideas about evolution for the intelligent biology student than any of the preceding volumes.

I have deliberately left the best book of the batch until last, for Professor Ford's book is a classic and is nearer to the original literature on the subject than any of the others. Its inclusion in the list arises solely from the fact that it has now most sensibly been issued in paperback form which should make it more accessible to both undergraduate and graduate students in the biological sciences. Though not everybody will agree with all that Professor Ford says, for the book is very much a personal view, he, together with Dobzhansky (and not only the latter, as Ayala and Valentine would have us suppose), have surely contributed more to our understanding of selection in natural populations than any other two men. □

M.J. Lawrence is Senior Lecturer in the Department of Genetics at the University of Birmingham, UK.

Genetic variability

Alan E.H. Emery

Laboratory Manual of Genetics. By A. M. Winchester. Pp.148. (C. Brown; Dubuque, Iowa, 1979.) $5.95. *Investigating Chromosomes.* By A. F. Dyer. Pp.138. (Edward Arnold: London, 1979.) Paperback £6.75. *Understanding Genetics.* Second edition. By N. V. Rothwell. Pp.682. (Oxford University Press: Oxford, 1979.) £14. *The Elements of Genetics.* By I. H. Herskowitz. Pp.442. (Collier-Macmillan: West Drayton, UK, 1979.) *Human Genetics: A Selection of Insights.* Edited by W. J. Schull and R. Chakraborty. Pp.361. (Dowden, Hutchinson and Ross: Stroudsburg, Pennsylvania, 1979) $30. *Human Genetics: Problems and Approaches.* By F. Vogel and A. G. Motulsky. Pp.700. (Springer: Berlin, Heidelberg and New York, 1979.) DM98; $53.90.

A NUMBER of textbooks of genetics have been published this year. But they differ so much in approach and content that it is not possible either to compare them or to present them under any unified theme.

Two essentially practical guides which I found appealing are A. M. Winchester's *Laboratory Manual of Genetics* and A. F. Dyer's *Investigating Chromosomes.* Winchester's book is a truly laboratory manual with practical information on such topics as the making of *Drosophila* culture media and the preparation of root tip mitoses (though not animal mitoses). Much of the book, however, is devoted to answering problems relevant to material given in the text. There are work sheets for answers but no solutions are given. It embraces both plant and animal genetics and there are useful sections on human genetics including the preparation of karyotypes from photomicrographs of stained chromosome spreads. For a first course in general genetics this laboratory manual could be most valuable.

Dyer's book is also very practical but at a more advanced level and is mainly concerned with the cytogenetics of flowering plants. The structure and behaviour of chromosomes are studied using essentially one basic preparative technique which is described in detail. It is well illustrated with simple line drawings and photomicrographs, and details are provided of the chromosome constitution of many flowering species. Each chapter concludes with a list of references for further reading. This book will be of particular value in departments of botany.

Turning now to student textbooks of general genetics we have N. V. Rothwell's *Understanding Genetics* and I. H. Herskowitz's *The Elements of Genetics*. Both authors have had considerable experience in teaching genetics over the years and this is reflected in the clarity of their respective texts. Rothwell's book is perhaps slightly more advanced. Examples are chosen from a wide variety of organisms from phage to man. The sections on molecular genetics are excellent. It is extremely well illustrated with line drawings and each chapter concludes with up-to-date references and review questions, answers to which, teachers will be relieved to hear, are provided at the end of the book. There is also a very good glossary. How this book will fair in the face of many competitors will only be decided by students and teachers who work through it. Certainly it is a very attractive textbook.

Herskowitz's book is basically a simplified version of his *Principles of Genetics* (Collier-Macmillan: West Drayton, UK; second edition, 1977) which I reviewed in *Nature* two years ago and concluded that this is one of the best undergraduate textbooks of general genetics currently available. But whereas the *Principles of Genetics* is essentially a complete textbook covering the entire field and suitable for a one-year course, the present text will fulfill the needs of a one-term course. For this purpose I have no reservations at all in recommending it. It is very up-to-date and there is also sufficient material on human genetics for those in health science courses. Each chapter concludes with a summary and questions (for which answers are provided), and references for further reading. There is also a glossary of terms. It deserves to be successful.

Two International Journals

IMAGERY and REMOTE SENSING including CLOSE-RANGE PHOTOGRAMMETRY/ IMAGERY

Here is a highly topical and practical journal with a difference. The new-style approach will enable subscribers to enjoy, in easily understood magazine-type text, reading about all the international developments in these highly specialised technologies, the people behind them, and all those specialists who apply their skills to interpret the imagery produced from the complex instrumentation systems. In addition more conventional academic-type research articles and reviews in both theoretical and practical aspects will be included, with particular emphasis on interpretation.

Beside the conventional fields to be covered, such as geology, hydrology, forestry, etc. this journal will include natural disaster investigational reports, image transmissions from extra-terrestrial probes, satellite/avionic tracking and optical imaging systems, thermal imagery, military applications in peace and war, and aerial/underwater archeology.

Initially 5 issues a year; A4 format. Subscription: £43 one yer, 20% discount 2 years, 30% discount 3 years.

IMAGERY and REMOTE SENSING ABSTRACTS

This will cover the same fields as the main journal (but excluding the Close-Range Imagery Supplement) with an initial output of some 5,000 abstracts in over 1,000 pages.

5 issues. Subscription: £97 one year, 20% discount 2 years, 30% discount 3 years.

Circle No. 19 on Reader Enquiry Card.

Finally, two recently published books on human genetics merit special consideration. The first consists of a selection of 26 classic papers in human genetics with comments by the editors, W. J. Schull and R. Chakraborty. This is Volume 10 in a series of *Benchmark Papers in Genetics*. In his Foreword, the series editor, David Jameson, states that papers have been selected which "demonstrate both the development of knowledge and the atmosphere in which that knowledge was developed. There is no substitute for reading great papers". There is little doubt that students should be encouraged to read the original papers in which major contributions to a subject were made. The papers in the present volume are arranged into three sections. The first section is largely historical and deals with the formal genetics of man with selections from such as Garrod, Bateson, Farabee, Landsteiner, Morton, Edwards and Haldane. The second section is concerned with the relationship between genes and chromosomes and human disease, and the selections here include papers by such as Lejeune, Carr, Pauling, Levine and Penrose. The third section is concerned with the nature and maintenance of genetic variability in man and includes papers by Haldane, E. B. Ford, Hirschfeld, Allison and Harry Harris. The editors contribute a final chapter on some of the social, ethical and legal problems which have been precipitated by recent developments in human genetics.

It is interesting to compare this selection with a similar one edited by S. H. Boyer in 1963 *(Papers on Human Genetics,* Prentice-Hall: Englewood Cliffs, New Jersey). Inevitably, and despite protests by the editors of such volumes, the selection of papers for inclusion will reflect, to a greater or lesser extent, the particular interests of the editor himself. Thus, Boyer's book leans more toward biochemical genetics, and Schull and Chakraborty's book toward population genetics. Interestingly the authors of these two books agree on only four papers: Garrod on alkaptonuria and chemical individuality; Pauling on sickle cell anaemia as a molecular disease; Allison on protection from malaria afforded by sickle cell anaemia; and Lejeune on the chromosome constitution of mongolism. I would therefore recommend both books to any would-be student, though in both he will find little in the area of clinical genetics, for example seminal papers by Carter, Clarke, Lenz and McKusick. Also I think I would take issue with Schull and Chakraborty's stated intention to ". . . distinguish between those creative acts with no apparent, immediate antecedents and those, which like the specification of the genetic code, may have been creative from the laboratory viewpoint, but represent the culmination of an intellectual ferment so pervasive as to dominate the activities of numerous laboratories. . . . surely a contribution of the former kind does not lie outside the prospects of any gifted scientist whereas the latter too frequently depends on accoutrements rather than insight". I would contend that in science the former is in fact rare and that almost all developments, including those in human genetics, are the result of selection, reshuffling, combining and synthesising of already existing facts, ideas, faculties, and skills. This is of course elegantly argued by Koestler in his *The Act of Creation.* Nevertheless this is an excellent collection of papers and the editors' comments are informative, interesting and germane. It can be highly recommended.

The second book on human genetics is by F. Vogel and A. G. Motulsky, whose expressed aim has been to produce a book which is ". . . a fairly thorough and up-to-date treatise on the conceptual basis of the entire field of human genetics and its practical applications". In this they have been completely successful. It is as thorough and precise as Vogel's earlier text *(Lehrbuch der Allgemeinen Humangenetik,* Springer, 1961) but is much more modern in outlook with less on anthropology and mathematical genetics. The current text is comprehensive and covers all aspects of human genetics and, as would be expected of authors as internationally regarded as these two, it is authoritative. It is illustrated by 420 very clear figures, and there are over 1,700 references provided for further reading. There is both an author index as well as an extensive subject index, and there are nine appendices into which are collected some of the more mathematical treatments of individual subjects. Despite its thoroughness, however, clinical aspects of the subject are largely ignored. Nevertheless, this is likely to become the standard postgraduate textbook concerned with the science of human genetics for many years to come. It is an excellent book and can be highly recommended. ☐

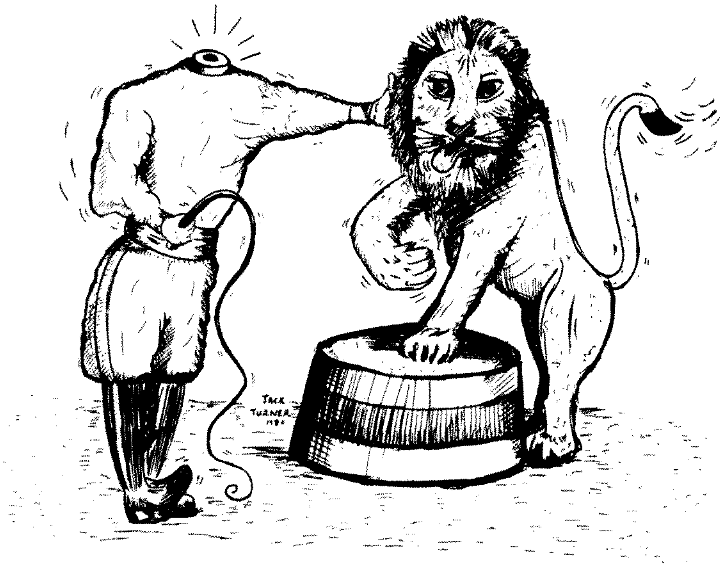
Managing wildlife

T.H. Clutton-Brock

Wildlife Management. By R.H. Giles. Pp.416. (Freeman: San Francisco and Reading, 1979.) £11.40.

As human populations grow and plant and animal populations shrink, it becomes increasingly important for the former to control and manage the latter. The pressing need for trained managers has produced an eruption of wildlife management courses and Giles' book provides an introductory text for this growing market. The book includes chapters on the analysis and manipulation of animal populations, on habitat description and design, on controlling the effects of human populations and on the problems of managing particular groups of animals, from fish to bears.

Wildlife Management is written in an easy, colloquial style, and provides many clearly worked examples of numerical techniques and a list of study questions at the end of each chapter. It has more than its share of facile statements ("Wildlife management is a decision science; an extinct animal is one lacking survivors; all living populations are dynamic"), luxuriant verbiage ("People are an integral part of the population-habitat-people triad of wildlife management (see Figure 1-1)") and unnecessary jargon ("feedforward" for shaping the future of a system; "ecological amplitude" for the range of conditions in which an animal can survive; "opportunity cost" for the compensation that people require to forego behaviour which might harm wildlife). And to an English reader, a proportion of the section headings are ambiguous: for example, it was not immediately clear to me that sections on *Alpha-Person Theory* and *Waterfowl Violations* would deal with analyses of who breaks game laws and the frequency with which legislation involving waterfowl is infringed.



"Don't worry, it'll be all right on the night."

Just what is wildlife is not, according to Giles, very clear. Game species are definitely wildlife but wild flowers, lichens, viruses and nematodes are not. Butterflies may or may not be and fish are sometimes excluded (apparently because of the wiles of a US fisheries commissioner who persuaded Congress to change the name of the US Biological Survey to the US Fish and Wildlife Service, thus providing his particular branch of science with a place in the sun but consigning fish to an ecological purgatory somewhere between birds and invertebrates). This somewhat arbitrary selection, Giles argues, is necessary because "there is a danger of opening a conceptual umbrella so wide that it covers all biology . . .".

But surely this is precisely what wildlife management should aim to do. It is unfair to blame Giles for the implied dichotomy between wildlife biology and ecology since this is common in the wildlife literature. However, the attitude is a dangerous one, especially in an introductory text, for it could cause wildlife managers to believe that they do not require a close acquaintance with ecological and biological theory. This is far from the case and ignorance of fundamental principles can only produce mistaken management policies. For example, a better knowledge of modern developments in ethological and evolutionary theory would surely have led Giles to modify his views that disease may have evolved as a density-regulating mechanism in some species and can be 'healthy' for such populations; that there is very little evidence for the inheritance of behavioural traits; and that inbreeding seldom has deleterious effects (pages 38 and 75). Such misconceptions could well have a dangerous effect on management policies. Moreover, only a broad understanding of ecological theory will allow managers to predict how previously unmanaged populations are likely to react to novel policies. Wildlife management is not an art form evolving into a separate science, as Giles suggests in his opening chapter. It is one branch of ecology and will only suffer if it is separated from other areas of biology. ☐

Adaptation and regulation

D. L. Ingram

Principles of Animal Physiology. By J. A. Wilson. Second edition. Pp.891. (Collier-Macmillan: West Drayton, UK, 1979.) £16.45; $30.20. *Animal Physiology. Adaptation and Environment.* By K. Schmidt-Nielsen. Pp.560. Second edition. (Cambridge University Press: Cambridge and New York, 1979.) Hardback £22.50; paperback £6.95. *Adaptation to Thermal Environment.* By L. E. Mount. Pp.333. (Edward Arnold: London, 1979.) Hardback £16; paperback £7.50.

THESE three books all share the common themes of adaptation and regulation; but the scope of each is quite different.

Principles of Animal Physiology is a comprehensive textbook covering the whole field of animal physiology, both vertebrate and invertebrate, in nearly 900 pages. It is written entirely by one author and the fact that it is in its second edition must mean that it has been well received. The central theme with which the author has attempted to weld this wide variety of topics together is regulation, an idea which is in accord with the modern view of physiological systems seen in terms of engineering and mathematical models. A book by a single author has the advantage of the same style throughout; but the subject covered here is so great that it would be very surprising indeed if all the facets were covered with a great depth of understanding.

Just as writing on such a wide range of subjects has its difficulties so does reviewing this type of book, and those chapters which are close to my own subject inevitably attracted the greatest attention. There are places in the sections on energy exchange and thermoregulation where I feel that the specialised knowledge which can only be acquired by close contact with the subject is lacking and there are occasional errors. The student who comes new to the subject, however, is presented with material which is free from numerous qualifying statements and will learn the more subtle points at a later stage in his study.

The book begins with a section on the properties of living systems in which organisation at the cellular level is covered. In the second section the regulatory systems such as the contractility of cells, the nervous system and hormones are described. Finally, there is a section in which nutrition, thermoregulation, circulation, and water and solute regulation receive attention. There is also a good bibliography. Each chapter is very well illustrated with diagrams and figures, some of which have been taken from published work and some of which are the author's own. Numerous tables provide the student with a wealth of information and there are several charts presenting biochemical pathways and structural formulae of physiologically active compounds. The book is directed chiefly at the American market and would certainly provide enough material for a general degree in physiological zoology. The hard-pressed student will find all the topics covered in his course in a single book and this will have obvious attractions: but the more advanced student will need to consult other texts. The author has not attempted to cover mammalian physiology in the detail which would be required in courses for a medical or veterinary degree for which there are already a good selection of books.

Animal Physiology: Adaptation and Environment, also in its second edition, is a really excellent book, covering as its title suggests a particular aspect of physiology. The author himself describes the book as elementary, and although it is true that the background required is minimal, it would be a mistake to regard this as just an elementary text. There will be very few experienced physiologists who will not gain a greater understanding of their subject from this account. Many topics which may seem difficult in other books are presented here in such an easy manner that the reader has understood the point before he realises there could be any problem. The wide range of research and discussion in which the author has engaged in various places all over the world has provided him with an understanding that ensures that just the right examples are always used to illustrate a point.

The book does not, however, make any claim to being a complete textbook of animal physiology, and although both invertebrates and vertebrates receive attention, the subject matter is intentionally selective. Physiological systems are dealt with in five parts. The first is headed oxygen and deals with respiration in water and air, and the transport of gases in the body. The second is concerned with food and energy. The third and fourth parts cover temperature, and osmotic regulation. In the final part there is a discussion of movement, integration and the way animals deal with information. The text is well illustrated and there is a good selection of references. I think that this book will serve two functions, one as an introduction which will raise the student's interest, and the other as an account for advanced students who want to organise the mass of facts which they have acquired into an understanding of principles.

Adaptation to Thermal Environment: Man and his Productive Animals is in many respects like an expanded second edition of the author's earlier successful book which was concerned with the climatic physiology of the pig, and is now out of print. This book is much more specialised than the other two reviewed here, being devoted entirely to the thermal aspects of the environment. This general topic has been the subject of several specialised meetings and as in many other branches of physiology considerable progress has been made during the past three decades. The author gives a well presented and highly factual account of the field with particular emphasis on the quantitative aspects of the subject and includes over 500 references to reviews and original papers.

In the first half of the book the nature of heat exchange between the animal and its environment receives very competent treatment and the physical aspects are presented in a way that should be understandable to students without a detailed knowledge of physics or mathematics. Many of the tables and figures are of use not only as illustrations of the text, but also as a valuable source of reference. In the second half the author deals with the various sorts of environment which animals encounter and concentrates in particular on the reactions of those species which are of economic importance, as well as to man himself.

Students of applied biology will find this book of special value because a great deal of information has been collected from a wide range of sources and presented in a digested form. Although the subject matter is specialised, the book is not an advanced text and is suitable for students with an elementary knowledge of biology and physics. I feel that its particular success lies in demonstrating the ways in which the reactions of animals to their environment are governed by the rules of physics. For this reason it may well find a readership outside the usual scope of biology amongst engineers and designers. ☐

D. L. Ingram is Senior Principal Scientific Officer at the ARC Institute of Animal Physiology, Babraham, Cambridge, UK.

All you need to know about proteins

C.C.F. Blake

Principles of Protein Structure. By G. E. Schulz and R. H. Schirmer. Pp. 314. (Springer: New York, Berlin and Heidelberg, 1979.) £13.95.

It is an extraordinary fact, often taken for granted, that just one class of molecule, the proteins, is responsible for *all* the active functional aspects of biological organisms, and for much of their structure as well. Whether one considers catalysis, metabolite transport and storage, molecular defence, blood-clotting, hormonal control, gene expression and muscle contraction; or bone, tendon, membranes and cytosol: in all these processes proteins are the central, active principle. Luckily this vast diversity of protein function is not paralleled by an equivalent diversity of protein structure: in fact the principles of protein structure are remarkably simple. The past 20 years have seen an absolute avalanche of detailed information on the structure of proteins which now provides a firm foundation for understanding the systematics of protein structure and function.

Schulz and Schirmer's *Principles of Protein Structure* is the first comprehensive attempt to assemble the knowledge gathered over these last two decades. The first part of the book is broadly analytic. Starting with the types of amino acids and the structural implications of the peptide bond, Schulz and Schirmer take us through the covalent and non-covalent forces that determine the patterns of folding and association of polypeptide chains. There then follow chapters on the prediction of secondary structure; thermodynamics and kinetics of chain folding; protein-ligand interactions; and a final chapter on the structural basis of protein function. This second part is broadly synthetic, attempting to use the information from the first part to understand the folding of proteins and the acquisition of function. Unfortunately this logical scheme is interrupted by two oddly positioned chapters on representation of structure and on protein evolution. That the authors feel some unease at the organisation of the book is indicated by their injunction to begin at chapter 7! That is scarcely necessary; chapter 1 is a good enough starting point, but new readers should be warned that chapters 7 and 9 are misplaced.

Having disposed of this minor criticism, I can welcome this book with wholehearted admiration. The topic could so easily have led to a diffuse descriptive text, whereas what is presented is analytical and tightly argued. Each chapter is multiply subdivided which makes for easy reference. Lest anyone be concerned about the command of language of two German authors, Schulz and Schirmer write in a lucid and, at times, elegant English that is never less than a pleasure to read. All in all a totally recommendable book. □

C. C. F. Blake is Lecturer in Molecular Biophysics at the University of Oxford, UK.

Welcome enzymology

G. Lowe

Enzymatic Reaction Mechanisms. By C. Walsh. Pp.978. (Freeman: San Francisco and Reading, 1979.) £18.30.

Enzymology is a subject which has relevance to and devotees from a wide range of disciplines. In this most welcome addition to a growing number of texts the author's approach is based on the chemistry of the reactions catalysed. In this way he has collated the transformations of metabolites in biological systems into a relatively few types of chemical reaction.

The book is in five main sections. In Section I the chemistry of the reactions to be dealt with in the remainder of the book is considered and general comments made on enzyme specificity and catalysis. Section II is concerned with enzyme catalysed group transfer reactions. Acyl-transfer being the most thoroughly studied is considered first. Unfortunately a highly significant paper concerning the catalytic triad of amino acid residues in the serine proteases appeared too late to influence the discussion in the text, but was incorporated as a footnote. This is a nightmare any author faces who attempts to survey a rapidly developing subject.

For a textbook that is devoted to enzymic reaction mechanisms, it is refreshingly free from those algebraic expressions which make enzyme kinetics look so formidable. There is however a very useful account of the application of kinetic isotope effects and reversible inhibition of enzyme catalysed reactions. Glutamyl- and amino-transfer reactions are the subject of the next chapter and this is appropriately followed by two chapters on phosphoryl transfer which includes discussions on phosphatases, ATPases, phosphodiesterases and kinases. This group of enzymes has, however, been the focus of a good deal of attention in the last few years, and inevitably therefore some highly significant experiments concerning the mechanism of these enzymes do not appear. Nucleotidyl and pyrophosphoryl, and glycosyl transfer reactions form the remaining chapters of this section.

Section III which consists of seven chapters focuses on enzymes and their cofactors which catalyse oxidations and reductions. Enzymes using nicotinamide, flavin and pterin co-enzymes are discussed first and this is followed by metallo-enzymes which utilise copper or iron as the redox component in catalysis. Finally molecular oxygen as an oxidising agent is discussed in which one (mono-oxygenases) or both oxygen atoms (dioxygenases) are used.

Section IV is concerned with enzyme-catalysed eliminations, isomerisations and rearrangements. A general theme is less evident in this section. Eliminations and isomerisation are however usually general acid–general base catalysed reactions, whilst rearrangements, which are fairly rare in enzymology, are often dependent on co-enzyme B_{12}.

Section V covers enzymic reactions that make and break carbon-carbon bonds, so bringing together some of the most biosynthetically versatile reactions, and which frequently require cofactors, such as thiamine pyrophosphate, biotin and pyridoxal phosphate. In the final chapter of this section the chemical logic of metabolic pathways is discussed.

The author is to be congratulated on producing an exciting and very readable account of the chemistry of enzymatic reaction mechanisms. The presentation is excellent, and the text is remarkably free from trivial error. □

G. Lowe is in the Dyson Perrins Laboratory, University of Oxford, UK.

Scope and applications of enzymology

Keith F. Tipton

The Nature of Enzymology. By R.L. Foster. Pp.383. (Croom Helm: London, 1979.) Hardback £19.95; paperback £9.95.

THIS book was an ambitious undertaking in that the author has attempted to survey the properties and function of enzymes and the medical, analytical and technological applications of enzymology at a level that would be suitable for undergraduates reading biochemistry and related subjects such as medicine, pharmacy, and applied biology. In trying to cover such a wide field it is, perhaps, not surprising that some topics are treated in scant detail; for example, there is no treatment of the kinetic analysis of enzyme reactions involving more than one substrate, the treatments of allosteric and cooperative effects are not sufficiently detailed and lack correlation with structural data; and the treatment of enzyme-linked immunoassays is too brief to explain the approaches adequately. Many of these deficiencies are, however, ameliorated in part by the well chosen references to original papers and reviews.

The mathematical analysis of enzyme behaviour is the weakest aspect of this book and the section on reversible inhibitors contains some confusing errors. In some places, such as the section on the regulation of enzyme systems, the purpose of the mathematical treatments is not made clear.

The strength of this book lies in its treatment of the more applied aspects of the subject, and the sections on the applications and limitations of enzymological methods in medicine and industry are clearly presented and well illustrated with examples. The use of numerous examples to illustrate the points made throughout the book are most valuable and make it enjoyable to read. Because of its somewhat cursory treatments of some important aspects of enzymology I could not recommend this as a textbook for students reading biochemistry as their main subject. Despite the criticisms mentioned above, however, the book might be used advantageously for courses in which biochemistry was a peripheral subject and it could be recommended to anyone wishing to get an idea of the present scope and applications of enzymology. □

Keith F. Tipton is Professor of Biochemistry at Trinity College, Dublin, Eire.

Biochemistry texts

E.D. Saggerson

Elementary Biochemistry: An Introduction to the Chemistry of Living Cells. By Julian Davies and Barbara Shaffer Littlewood. Pp.346. (Prentice-Hall, Englewood Cliffs: New Jersey and Hemel Hempstead, UK, 1979.) *Biochemistry.* By F.B. Armstrong and T.P. Bennett. Pp.491. (Oxford University Press: Oxford, 1979.) £14.

THE stated objective of Davies and Littlewood is to show "that biochemistry is fun" in a book aimed at students not specialising in biochemistry. Whether it is fun or not, the result is a fine book that would make an adequate textbook for any student whose course does not demand the mastery of one of the larger standard textbooks or who wants firstly to read a simpler account of the general features of the subject.

The book, consisting of 16 chapters, has 346 pages of quite small print. The style is simple and attractive and the figures are clear. The scope of the book is quite wide, opening with a chapter on cell structure and organisation, organic biomolecules and the elemental composition of cells. Three chapters are then devoted to protein structure and properties, determination of protein structure (protein separation, sequence determination, X-ray crystallography) and a simple description of enzyme function. The chapter on enzymes does not make recourse to a single equation but manages to describe the salient features of enzyme action together with sections dealing with the use of enzymes in medical diagnosis, industrial uses of enzymes, and enzyme inhibitors. The latter section is interesting since the actions of a number of poisons are discussed together with the actions of a number of antibiotics as enzyme inhibitors.

The general features of intermediary metabolism are covered in approximately 120 pages including, in the section on lipids, discussion of membranes, lipoproteins and the involvement of lipids in heart disease. Two chapters are devoted to nucleic acid structure, transcription and translation including a small section on the use of recombinant DNA in 'genetic engineering'. Human genetic diseases are also briefly considered in this part of the book. Regulation and control are specifically dealt with in a separate chapter which introduces the concept of the operon using the control of the expression of the *lac* operon as an example, briefly considers regulation of enzyme activity and contains a section on hormones. This latter section, which considers plant hormones and pheromones as well as mammalian hormones, is probably too brief and superficial to deal adequately with the topic but does contain some useful summary tables of hormone structure, source, effect and symptoms of excess or deficiency. The final two chapters in the book are unusual for an elementary biochemistry text. One deals with viruses (structure, life cycle and possible involvement in cancer), the other with antimicrobial agents. There is also an appendix setting out some important aspects of organic chemistry that are relevant to biochemical reactions.

In conclusion, the authors have done well in producing a very sound book which may well appeal to a wide readership.

Armstrong and Bennett's is a general textbook on the subject containing more material than the book by Davies and Littlewood but considerably less than the established textbooks by Lehninger, McGilvery, Stryer, and so on. 467 pages are contained in 24 chapters but the quantity of text on each page being quite small together with a large number of figures means that the content is less than at first sight. The contents include the history of biochemistry, protein structure, simple enzyme kinetics, carbohydrate, lipid and nucleic acid structure (one chapter on each), coenzyme function, six chapters on metabolism (including one on the basics of human nutrition), a chapter on hormones, and three chapters covering molecular genetics and protein synthesis.

The text is clearly and concisely presented and the figures are good. However, I found the index rather incomplete and there are some serious omissions in the section on intermediary metabolism. Certain aspects of lipid metabolism in particular are grossly neglected. I could find no sections dealing with fatty acid and sterol biosynthesis or with ketone body metabolism. Glycogen metabolism is barely mentioned except when its regulation is used as an example of hormonal control. Gluconeogenesis also received scant attention with no consideration of its physiological role.

Priced at £14, I do not feel that this book will be competitive on the student market. □

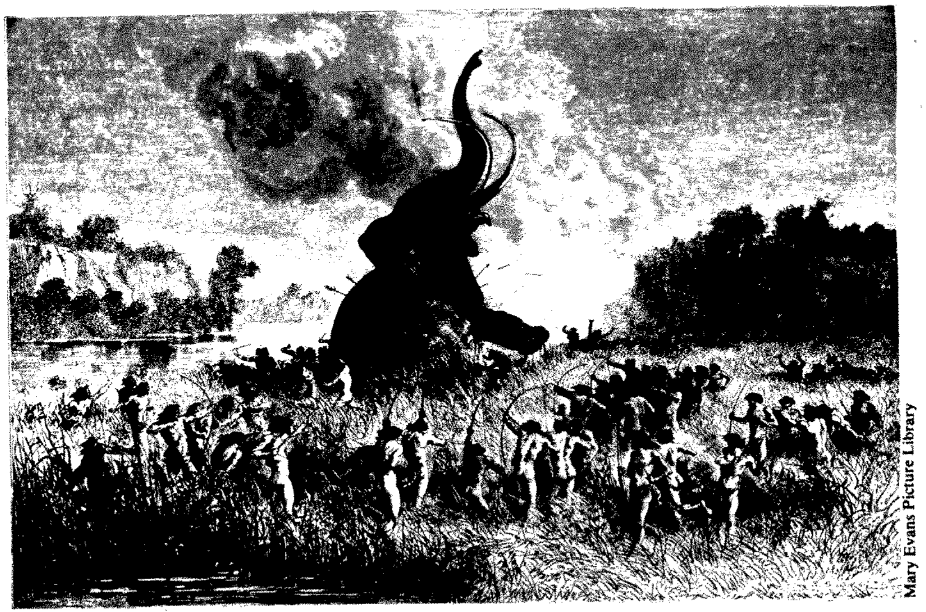
David Saggerson is Lecturer in Biochemistry at University College London, UK.

Food provision and energy resources

K.L. Blaxter

Food Energy and Society. By D. and M. Pimentel. Pp.165. (Edward Arnold: London, 1979.) Paperback £3.95.

THE dependence of food provision for man on sources of energy other than contemporary sunshine has been dealt with in a spate of books and articles published in recent years. The Pimentels' book, through numerous examples in the text and in tabular form, provides a wider basis of illustration of this dependence than most and in so doing a wider perspective. It is designed for undergraduate teaching and will be useful. Indeed, as much of the information quoted is given in original units, it will provide undergraduates with useful exercises in conversion of units to a common basis.



Early man solving the problems of food provision

Mary Evans Picture Library

The presentation commences with primitive hunting systems of providing food, progresses through simple types of agricultural systems to deal finally with modern ways in which food eventually reaches the dining table and the support energy costs of the many separate processes involved. Such a descriptive account should lead to ideas about strategies to deal with impending future problems. As have others, the Pimentels point to the necessity of stabilising population to stabilise food demand and to the desirability of replacing animal products by plant products in the human diet so to avoid the trophic axe associated with secondary production systems. These vegetable food products can certainly not be American canned corn for they show that to produce a can containing 455 g corn with an energy value for man of 1.6 MJ entails the expenditure of 12.6 MJ support energy as fossil fuel to process, package, transport, distribute, store and cook the corn. No doubt they had less sophisticated systems for the distribution of primary agricultural products in mind. It is a great pity that a book designed for undergraduates terminates on the pessimistic theme: "Although man's scientific expertise will help alleviate some of the world shortages, science cannot solve the problems the world faces today". It would have been better, having pointed out the problem, to have emphasised the challenge that that problem poses. □

Sir Kenneth Blaxter is Director of the Rowett Research Institute, Aberdeen, UK.

Marine biology

A.B. Bowers

Marine Biology. By J. Reseck. Pp.257. (Prentice-Hall International: Englewood Cliffs, New Jersey, and Hemel Hempstead, UK, 1979.) £10.75.

JOHN Reseck's book reflects his ideas on how marine biology should be taught to senior classes in schools and introductory classes in universities. The first part deals with physical and biological processes important to the understanding of life in the sea, the second with environments and ecological niches, and the third with taxonomy and characteristics of marine animals. He places equal importance on interesting and instructing students. The style is direct with short sentences and clear explanations, though word usage and sentence construction will often irritate grammatical purists. Each chapter begins with definitions of technical terms which might be unfamiliar to the reader, and ends with review questions to check his understanding of the material presented. The book is generously illustrated, with more black-and-white photographs than line diagrams. There is a selected reading list at the end and a good index.

The scope of the book is impressive: topics range from primary production to man's use and misuse of the sea, from polar seas to tropical mangrove swamps, and from protozoa to sea-birds and mammals. Most attention is given to North American environments and fauna; the algae deserve fuller treatment. Unfortunately there are many shortcomings in presentation of the material that could easily have been corrected before publication. Some figures are misplaced in relation to the text. The labelling of several important diagrams is inadequate or inaccurate. Many of the photographs are inappropriate; some of them would puzzle a specialist because the unusual viewpoint, poor contrast and lack of scale make them difficult to interpret. There are careless errors in the text.

The author states that the book is designed for the student to buy and read through, to be complemented by reference books from the library. I would certainly encourage teachers to buy it, but suggest that they make their own decision about recommending it to students in its present form. A carefully revised edition would be very useful. □

A.B. Bowers is a Senior Lecturer in Marine Biology at the University of Liverpool, UK.

Oceans of literature

R.I. Tait

Oceanography. By J.J. Bhatt. Pp.322. (Van Nostrand, Reinhold: Wokingham, UK, 1979.) £12.10. *Ocean Science*. By K.S. Stowe. Pp.610. (Wiley: Chichester, UK, and New York, 1979.) £9.50. *Exploration of the Oceans*. By J.G. Weihaupt. Pp.589. (Collier-Macmillan: London, 1979.) £12.75. *Descriptive Physical Oceanography*. By G.L. Pickard. Third edition. Pp.233. (Pergamon: Oxford and New York, 1979.) Hardback $25, £12.50; paperback $9.95, £5. *Introduction to Physical Oceanography*. By J.A. Knauss. Pp.338. (Prentice-Hall: Englewood Cliffs, New Jersey and Hemel Hempstead, UK, 1979.) £19.45. *Oceanography: Units 1-16*. The Open University Course Team. (Open University Press: Milton Keynes, 1979.) From £3.25 to £7.50 for each of 7 volumes.

To those involved in the teaching of oceanography at University, the choice of suitable text books poses many problems. For introductory courses the range of books available can be divided into two categories: (1) those which attempt to cover all aspects of oceanography; and (2) those which specialise in only one of the related disciplines. The latter group is primarily intended for students wishing to study a particular branch of oceanography or perhaps those who, while specialising in one oceanographic discipline, require a background in another. As courses at University level are usually devoted to one or two disciplines only, category 2 texts are the prime requirement. Books in group 1, on the other hand, normally fall under the heading of "background reading" only. There is an abundance of such books on the market. They are usually lavishly produced, with photographs and diagrams of the highest quality; a valuable source of visual aids to the teacher but, because of their somewhat superficial treatment of any particular topic, of limited use to the serious student. They do, however, play an important role in popularising the subject and as such they constitute a valuable part of the oceanographic literature.

The group of books reviewed here is divided between these two categories. *Oceanography* by J.J. Bhatt, *Ocean Science* by K.S. Stowe and *Exploration of the Oceans* by J.G. Weihaupt are all good examples of category 1. *Descriptive Physical Oceanography* by G.L. Pickard and *Introduction to Physical Oceanography* by Knauss fall into category 2. The last volume to be discussed, the Open University course *Oceanography, Units 1-16*, although belonging to the first grouping, has a different format: it is basically a students' work book and as such is unique.

The three books in category 1, Bhatt, Stowe and Weihaupt, all encompass the broad spectrum of the subject including the history of oceanography, the geophysical origins of the Earth and ocean, the physics, chemistry, geology and biology of the sea as well as related topics such as ocean management. All are up to date in their approach to the subject. Of the three, *Oceanography* by Bhatt is perhaps the most attractively produced. Basic definitions are given in a marginal glossary and each chapter concludes with a summary and suggestions for further reading. Effective use is made throughout of photographs to illustrate modern instrumentation.

One consequence of reviewing several books together is that their relative weaknesses become accentuated. Bhatt suffers in this respect. It is about half the size of the books by Stowe and Weihaupt and as it covers much the same field, depth of treatment must suffer accordingly. There is always a danger that too superficial a discussion of any topic may be misleading. To give one example, a student reading the chapter on ocean circulation in Bhatt will not gain an insight into the true nature of the Coriolis force; nor will he understand geostrophic currents, particularly as the illustrative figure is incorrect. And there are many other examples of sketchy treatment. However, in spite of this fundamental weakness there is much good material in Bhatt. Although not of a sufficiently high standard for a University course it will undoubtedly find a place in the school library.

The other two volumes by Stowe and Weihaupt are very similar in content and presentation. Both are eminently suitable for a general course in oceanography or as background reading for students at a higher level. In Weihaupt each chapter is followed by suggestions for further reading; Stowe gives only a summary and no references whatever! However, he does back each chapter with a list of study questions (over 100 in some cases) which is an excellent idea.

Following an introduction to the history of the subject, both texts give a good account of the geological-geophysical aspects of oceanography. Stowe is particularly good on geophysics: he treats the subject at a somewhat higher level than Weihaupt who on the other hand has added an interesting chapter on the changing level of the sea. Climatic aspects of the oceans are adequately covered in both books, but neither author gives sufficient attention to the heat budget of the ocean. Weihaupt is weaker on the dynamics of ocean currents. The T-S diagram receives insufficient treatment in both texts but waves and tides are adequately covered for the intended audience.

Both books have extensive and informative sections on marine biology. As a non-expert in this subject I found Weihaupt here perhaps easier to read. Each volume concludes with a stimulating chapter on ocean resources and man's impact on the ocean environment. There is little to choose between these two books. If I had to select one it would probably be Stowe, if only because he achieves overall a slightly higher scientific level than Weihaupt. However, both texts are very good. I would rate them as amongst the best books on general oceanography to appear since *The Oceans: Their Physics, Chemistry, and General Biology.* (Sverdrup *et al.*, Prentice-Hall: Englewood Cliffs, New Jersey, 1942).

Descriptive Physical Oceanography by G.L. Pickard is a well known oceanographic textbook which is now in its third edition. As a specialised text it goes more deeply into a physical description of the world's oceans than any of the books discussed above. Where appropriate, some minor changes have been made between the second and third editions to bring the subject matter up to date, but essentially text and diagrams remain unchanged. An important innovation, however, has been the conversion to SI units and the addition of a useful appendix on the units used in physical oceanography.

There is almost no mathematics in Pickard. The author's aim was to cover all aspects of physical oceanography which could be described in non-mathematical terms, with the intention that a companion volume would follow covering the dynamical side of the subject. This volume has at last appeared: *Introductory Dynamic Oceanography* (S. Pond and G.G. Pickard, Pergamon: Oxford and New York, 1978). Together with Pickard's descriptive oceanography it fills a long felt need for a basic text at undergraduate level, or for graduate students embarking on a career in physical oceanography. Whether description and theory should be divorced as completely as they are in Pickard, and Pond and Pickard, is a debatable point. My personal view is that it is a mistake. Integration of description with analysis can often be helpful in the understanding of the latter. (See Knauss below.)

In comparison with all the other books discussed here, the format of Pickard appears very drab indeed. Apart from the cheap production (intentional, but somewhat improved in the third edition) the most obvious shortcoming is the paucity of illustrations. The reader is often faced with unrelieved pages of text, whereas a few simple diagrams would have provided clearer insight with less tedium. I have little doubt that many students find it a rather dull book. However, in spite of this, I shall continue to recommend it to my students: the subject matter is good and presented at the right level for the descriptive part of an undergraduate course in physical oceanography.

In his *Introduction to Physical Oceanography* J.A. Knauss provides a text intended for "beginning graduate students and upper division undergraduates". As such it is set at a relatively high level of mathematical rigour compared with the other books. Use is made of vector notation and Cartesian coordinates throughout; some specialised derivations relating to the equations of motion and the wave equations are relegated to an Appendix which seems a good idea as it leaves the text free of excess mathematics. Another good point is the clear listing on the inside of both front and back covers of all symbols used. The Appendix also contains four pages of useful tables relating to the physical properties of sea water.

The book is very well written and the material is logically presented. The numerous illustrations of excellent quality are used skilfully in conjunction with a clear prose style, making even the more difficult concepts readily understandable. A reasonable balance is achieved between description and analysis and one of the features of the book is the use, particularly in the dynamical sections, of examples from the real ocean to illustrate theoretical points made. It is perhaps inevitable that not all sections of the book should achieve the same standard. Chapters which stand out as attaining a high level are those on the physical properties of sea water (with the appended tables), the heat budget of the ocean and the four chapters on ocean dynamics, although here some readers may be disturbed by the rather unorthodox development of the balance of forces "without Coriolis" followed by the balance "with Coriolis" instead of the usual treatment of forces "without friction" and "with friction". I cannot avoid mention of one unfortunate error: in Fig. 7.1 the direction of the geostrophic flow in three of the cells shown is reversed!

In other sections the topics are not treated to the same depth and the book as a whole cannot therefore be considered as giving a balanced view of the subject. Notable weaknesses are an inadequate treatment of boundary effects and insufficient development of the description of oceanic water masses and T-S analysis. The chapter on tides is also disappointing. However, a comprehensive text to the standard of the best chapters would require a much larger book. As it stands it is overall a good text which goes a long way towards filling a persistent gap in the literature.

The Open University interdisciplinary course (S.334) in *Oceanography* is probably one of the best publications available at present, particularly in view of its impressive attempt to teach, rather than merely describe, the basic concepts of the subject. It comprises seven sections totalling 780 pages that deal with the physical, chemical, biological and geological aspects of the oceanic environment, as well as an appraisal of the complex political and economic problems which have arisen due to the exploitation of marine resources. The presentation of all the material follows a format of discussion, questions, answers, comments, self-assessment and revision. It incorporates clear diagrams which have been either reproduced from well documented sources, or specifically constructed to illustrate the points under discussion. Each section concludes with a comprehensive list of references and suggestions for further optional reading.

To assimilate the contents of this course without too much difficulty a student would require a basic knowledge of at least two of the major sciences, and in fact would have a considerable advantage if one of these was in the field of geology since there is a distinct imbalance in favour of this subject. However, every effort is made to accommodate the less experienced by punctuating the text with a liberal number of self-assessment exercises. Wherever possible the reader is encouraged to recall and compare different facets, which are in fact interrelated, of an oceanic phenomenon, although previously these might have been treated solely as a particular physical, chemical, or biological event. Indeed, the student should be prepared, for example, to consider such diverse oceanic processes as those that control: the broad eastern boundary currents with their associated regions of coastal upwelling; the balance between oxygen concentration and biological consumption; the rates of production and growth of commercial fish stocks; the sediment accumulation in the deep ocean; and the present legal arguments regarding international straits, artificial installations and marine pollution. Whatever the topic, the information provided is invariably sufficient to enable the reader to gain an insight into the subject which is seldom achieved in the more superficial presentation of many oceanographic text books. The OU team have produced a most commendable script. □

Isotope geology

Grenville Turner

Lectures in Isotope Geology. Edited by E. Jager and J.C. Hunziker. Pp.329. (Springer: Berlin, Heidelberg and New York, 1979.) DM49.00, US$27.00

THIS book on isotope geology is the outcome of a two-week course of lectures to graduate and postgraduate earth scientists delivered by an international group of scientists at the University of Berne in 1977. It contains 24 chapters and covers topics related to the standard isotope dating methods (Rb-Sr, K-Ar, ^{40}Ar-^{39}Ar, U-Th-Pb and fission tracks) as well as the principles and applications of stable isotope geochemistry. According to the preface and flyleaf it is intended to be an introduction to isotope geology aimed at geologists rather than isotope specialists. My own feeling is that it is not a book to read without some prior knowledge. As a textbook for a course on isotope geology it does not compare at all well with the excellent book by Faure, *Principles of Isotope Geology* (reviewed in *Nature* **272**, 103 (1978)).

In fact, I was rather disappointed by this book. Before reading it I made a mental list of some of the topics in isotope geology which I regard as currently the most exciting. My list included the chronology and early evolution of the Earth's crust, the history of crust and upper mantle evolution based on modern studies of Nd-Sm, Rb-Sr and Pb isotopes, isotopic anomalies in the early Solar System and the chronology of the early Solar System. Apart from a short chapter on Archaean geochronology, an even shorter one on mantle geochemistry, and a discussion of crust and mantle interactions in the chapter on lead geochemistry, these exciting fields are virtually ignored. The contributions to the book are also rather patchy in the sense that 6 of the 24 chapters were of 5 pages or less (the shortest on the now defunct total lead method was 2 pages!). Two authors were particularly guilty in this respect. I feel that the editors should either have rejected some of the contributions or demanded more substantial work. I realise that to construct a coherent whole from a list of 17 contributors is not an easy task. Nevertheless, it is an essential one for a book intended to be used as 'an introductory course'.

This review has emphasised the bad points of the book; like the well known egg it has some parts worthy of consumption and several authors have given worthwhile summaries of particular fields. As a rough but not entirely correct guide, the usefulness of the chapters correlates with their length. Geologists and geochemists entering or already occupying the isotope field will therefore find parts of the book useful. However, considering its high cost I would encourage them to consult a library copy before buying. □

Grenville Turner is Reader in Physics at the University of Sheffield, UK.

Cloud physics

J. Latham

A Short Course in Cloud Physics. Second edition. By R.R. Rogers. Pp.248. (Pergamon: Oxford, 1979.) Hardback £14.50; flexi £7.25.

THIS short book is written for postgraduate students entering research in cloud physics. The structure of the book is conventional and logical. The initial chapters are concerned with meteorological thermodynamics. The appropriate thermodynamic laws and equations are first developed for dry air and are then extended to take account of the presence of water vapour. This leads to a discussion of static stability and air parcel buoyancy, which evolves naturally into an account of current understanding of mixing of air masses and theories of convection.

Three chapters are devoted to non-freezing clouds. The elements of homogeneous nucleation of water droplets are presented and then extended to take account of the role of condensation nuclei in the atmosphere. The subsequent growth of stable droplets by vapour diffusion is discussed and attention drawn to recent developments in the molecular kinetics of this phenomenon. The formation of raindrops by the stochastic process of collision and coalescence of cloud droplets is considered. The parallel processes — heterogeneous nucleation, vapour growth and accretion — occurring in clouds containing the ice phase are then discussed. An account is presented of the relative growth rates of precipitation by the coalescence and ice crystal processes.

A chapter is devoted to various properties of precipitation particles. The size distribution of the hydrometeors occurring in natural rainfall and snowfall are discussed. The formation of satellite drops by the processes of aerodynamic breakup of raindrops or the collision of drop pairs is considered, and it is shown how the latter process produces spectra similar to those observed. The aggregation and breakup of snowflakes, and the precipitation rates encountered in various meteorological circumstances are then outlined.

A useful account is presented of the role of radar in meteorology and cloud physics research. A discussion of the basic principles of radar leads to development of the relevant equations linking the received power to the properties of the precipitation scattering the radiation. This chapter concludes with a description of types of radar display and special techniques employed in cloud physics, such as Doppler radar.

Two chapters entitled 'Precipitation

Processes' and 'Severe Storms and Hail' are devoted to more macroscopic aspects of cloud physics. Various precipitation systems are described, attention being given to the airflow which governs the release and distribution of rainfall. A brief discussion is presented of the efficiency with which cloud water is transformed into precipitation. A detailed account follows of the dynamics and life cycle of severe storms. This leads naturally to a description of the formation of hail and the energy balance equations which govern the growth of hail pellets.

The final two chapters contain skeletal descriptions of current works in the important areas of weather modification and numerical modelling of cloud processes.

The problems for students presented at the end of each chapter are imaginatively devised and well balanced. It is helpful that in this second edition answers are given to odd-numbered questions. The book is modestly priced and serves as an excellent introduction to cloud physics. □

J. Latham is Head of the Physics Department of UMIST, Manchester, UK, and President of the International Commission on Atmospheric Electricity.

Inorganic analysis

F.J.C. Rossotti

Vogel's Textbook of Macro and Semimicro Qualitative Inorganic Analysis. By G. Svehla. (Longman: Harlow, UK, 1979.) £14.95. *Practical Inorganic Chemistry.* By G. Pass and H. Sutcliffe. Pp.242. (Chapman and Hall: London, 1979.) Paperback £3.95.

FOUR editions of Vogel's textbook appeared between 1937 and 1954, the heyday of qualitative inorganic analysis in British schools and universities. Twenty-five years later, Svehla has produced a fifth edition, in an age when less time is devoted to practical chemistry in British curricula and the popularity of systematic qualitative analysis has waned. One of the benefits of a sound grounding in qualitative analysis is that students become familiar with a great deal of phenomenological inorganic chemistry, for example, colours, solubilities and reactions in solution. A backwards swing of the pendulum would now be timely.

The systematic qualitative analysis of some 44 cations and 47 anions is described. Length and contents of the new edition are much the same as before. Two short chapters on interfering anions and on paper chromatography in the previous edition have been assimilated into other chapters and there is some shuffling of order. However, updating seems to have been modest. Thus the section on solvent extraction remains weak and largely irrelevant in its detailed content. It might, for example, have been helpful to students to inform them that systems of qualitative analysis, which rely entirely on solvent extraction, now exist. In this connection, citation of key references (as in the Vogel *Quantitative Inorganic* text) would have been helpful in much of the book.

The most disappointing feature of the new edition is the still antiquated treatment of reactions in solution. Thus ammonia and copper (II) ions do not yield a unique tetra-ammine (Dawson, 1900) but rather five mononuclear ammines in stepwise equilibrium (Bjerrum, 1931). The blood-red colour produced on mixing iron (III) and thiocyanate ions has been variously attributed to $Fe(NCS)_6^{3-}$ (third edition), $Fe(NCS)^{2+}$ (fourth edition) and now to $Fe(NCS)_3$ (fifth edition). In fact, six thiocyanato complexes coexist in stepwise equilibrium and in relative amounts which depend upon the free thiocyanate ion concentration. Discharge of the red colour by fluoride ions is not due to the formation of a unique complex FeF_6^{3-}, but rather to an array of mononuclear fluoro complexes. Moreover, it is doubtful whether the hexafluoro species exists at all in aqueous solution. These typical outdated misconceptions about the nature of interactions between inorganic species in aqueous solution seriously mar an otherwise useful bench-book.

By contrast, Pass and Sutcliffe's text deals with the practical inorganic chemistry that has so largely replaced qualitative analysis in British university curricula. The current volume is a paperback reprint of the second edition of 1974. It contains a wide variety of preparative exercises, together with some reactions of transition metal ions and applications of some instrumental techniques. The interweaving of a certain amount of theory with the experimental instructions, together with the modest length and price of the book, must make it attractive for many courses.

Arbitrary choices of topic are inevitable if space is at a premium, but the omission of solvent extraction from a chapter on separation techniques, which contains ion-exchange, seems somewhat surprising. Again, it is regrettable that instruction on Job's method of continuous variations persists in the 2nd edition. This archaic method is of very limited applicability, again by virtue of stepwise complex formation. □

F.J.C. Rossotti is a Lecturer in Inorganic Chemistry at the University of Oxford, UK.

Plasma physics

I.H. Hutchinson

Physics of High Temperature Plasmas. Second edition. By G. Schmidt. Pp.408. (Academic: New York, 1979.) $29.50.

THE dilemma of most didactic texts, particularly in relatively rapidly developing subjects, lies between a presentation of the historical development of the discipline and an essentially axiomatic exposition along what are seen as the most logical lines. Few general plasma physics texts follow as completely the latter, non-historical approach as the second edition of *Physics of High Temperature Plasmas* by George Schmidt. This bias is emphasised by the deletion of the first edition's quite detailed bibliographies accompanying each chapter, in favour of a very brief list of books at the end. However, perhaps because of this approach, the new edition gives very little evidence of ageing.

The coverage is very wide, including treatments of particle motion guiding-centre approximations, the derivation of the CGL approximation, two chapters on magnetohydrodynamics, Vlasov wave and instability analyses, bounded plasma effects and touching on relaxation and collisions. The bulk of the material new to this edition is contained in a chapter on non-linear waves, providing a good introduction to topics not often covered by general texts.

The book is fully committed to being self-contained in its development. In this it succeeds rather well, hardly every specifically appealing to the reader's credence ("it can be shown"). However, there are definitely occasions when rigour is sacrificed in claiming the self-evidence of statements which, on reflection, are plausible though not obvious. Such points are inevitable and not necessarily detrimental. Indeed, greater attention to minutiae might have made the exposition too formal. As it is, while the many examples that are worked out in depth are mostly of direct experimental relevance, the uninitiated are left wondering just how the results really work out with a laboratory plasma. The feeling is enhanced by the fact that what few illustrations there are of the results in action are mostly of computational simulations.

A remarkable success of this book is that it covers such a broad range of topics with significant depth in just four hundred pages. This is achieved, on the one hand, by a very happy choice of examples and lines of development of the subject. On the other hand, though, the prose is compact, sometimes terse, and the mathematical development inexorable; so that all but the most mathematically accomplished student must find it heavy going at times. Nevertheless, there are many valuable physical insights to be gained and we rarely lose sight of the physics behind the equations.

There are an annoying number of errors and misprints for a second edition. "Stellerator" is a typographical error since it appears elsewhere correctly, but "Tokomak" seems deliberate and is neither a consistent transliteration of the Russian nor in conformity with general usage.

There is not really a wide choice of general graduate level plasma physics texts. Teachers will welcome this quite up to date edition and researchers and students continue to appreciate its insights and breadth. □

I.H. Hutchinson is a Research Plasma Physicist at the UKAEA, Culham Laboratory, Abingdon, UK.

Basic organic chemistry

John Mann

Fundamentals of Organic Chemistry. By A.N. Nesmeyanov and N.A. Nesmeyanov. Pp.484. (MIR Publishers/ Central Books: London, 1978.) £4.50 each, £16 for set of 4 volumes. *Organic Chemistry.* By D.J. Pasto and C.R. Johnson. Pp.542. (Prentice-Hall International: Hemel Hempstead, UK, 1979.) Paperback £10.35. *Qualitative Organic Analysis.* By W. Kemp. Pp.183. (McGraw-Hill: New York and London, 1979.) Paperback £4.85. *An Introduction to Organic Chemistry.* By J. Carnduff. Pp.194. (Wiley: Chichester, UK, and New York, 1979.) £8.50.

THERE are no weighty tomes or glossy American textbooks under review this year. Instead, a Russian attempt in four, slim volumes, to cover the fundamentals of organic chemistry; a laboratory handbook of organic chemistry; a book of qualitative organic analysis; and an advanced school text.

The four-volume Russian work, *Fundamentals of Organic Chemistry,* by A.N. Nesmeyanov and N.A. Nesmeyanov is (I quote from the introduction) "designed for systematic study of Organic Chemistry, and covers a considerably wider field than a normal university treatment". Certainly the coverage is broader than in the average UK or American texts, and is more akin to that of Finar (*Organic Chemistry,* two volumes, Longmans: Harlow, UK, 1951) in its first edition. This resemblance extends to the old-fashioned representations of structures and stereochemistries, excusable in the ancient version of Finar, but not in a modern textbook.

Volume one commences with a full mathematical treatment of the theory of chemical reactions, and later does the same for electronic structure. Standard (in some cases antiquated) methods of preparation of saturated aliphatic compounds are then given, together with their main reactions, with not a curly arrow in sight. There are some good tables of physical constants, a rare sight in modern textbooks of organic chemistry; and the volume concludes with a discussion of the classical chemistry of unsaturated aliphatic compounds.

This leads, in volume two, on to optical isomerism, and some very poor representations of chiral molecules. It is here that the comparison with modern western textbooks is so stark: one only has to think of the splendid illustrations in Cram and Cram (*Essence of Organic Chemistry;* for review see *Nature,* **278,** 82; 1979), for example, to appreciate this fact. The reader is then led through sections on sugars (flat structures only), amino acids and polypeptides (no stereochemical structures at all), and alicyclic compounds. To be fair, this latter subject is dealt with in far greater detail than in any comparable text. The volume concludes with a chapter on physical methods of structure elucidation, comprising sections on mass spectrometry (here the reader is hurled straight into an exposition of Russian peptide sequencing using MS), nuclear magnetic resonance (again weak on fundamentals), and brief sections on infrared spectroscopy, and polarimetry. The comparisons with western textbooks are again rather unflattering.

Volume three includes aromatic and heterocyclic chemistry, and coverage of both topics is very extensive (295 and 121 pages, respectively). Some Russian specialities are stressed: many pages on the stereoisomerism of substituted biphenyls, and 44 pages on condensed aromatic systems.

In the final volume there is a comprehensive, if somewhat antiquated, treatment of organometallic chemistry, with a particularly extensive section on metal carbonyls (usually confined to inorganic texts). There is little mention of synthetic utility: hydroboration merits one page, whereas the Wittig reaction gets one mention in volume one, and half a page in this volume. Similarly, the section on carbanion chemistry contains no mention of current synthetic methodology. Terpenoids and alkaloids then receive a classical treatment, and the structures are particularly archaic here; but there is more steroid and alkaloid chemistry than in most student texts. However, the relevance of these secondary metabolites to pharmacology and ecological chemistry is ignored completely. The final chapters include discussions of nucleic acids, enzymes, and cofactors; and this is quite well done, apart from an appalling photograph of the myoglobin molecule (one of the few photographs in the book).

At its best this work is comprehensive though rather antiquated; but the overall impression is one of dullness — it lacks the vital spark and visual appeal of most western textbooks.

D.J. Pasto and C.R. Johnson have, in their new book *Organic Chemistry,* produced an excellent laboratory handbook for undergraduate chemists. The book is in three parts: basic laboratory techniques, spectroscopic methods, and qualitative analysis. The introductory chapter in part one starts from first principles, and leads the novice experimentalist through sections on laboratory safety, elementary first-aid, general equipment and its uses, a solvent list, and yield calculation. This is followed by a chapter on techniques of separation and purification, from recrystallisation, sublimation, and distillation, through to a good section on chromatography which includes HPLC. Part one concludes with a chapter on physical characterisation which is concise but adequate. It is worth comparing this part of the book with the first part of Vogel (*Textbook of Practical Organic Chemistry*; also reviewed last year: **278,** 82). This far weightier tome is much more comprehensive, but far less readable, whereas Pasto and Johnson have provided an introduction to the classical methods of organic chemistry in a form which students might even enjoy reading.

The second part commences with ultraviolet and visible spectra, then proceeds to a discussion of infrared spectroscopy, all of which is more than adequate for undergraduates involved in structure elucidation. The NMR section is very good, and includes ^{13}C-NMR, NOE, and shift reagents, as well as all of the fundamentals; and the subsequent section on mass spectrometry is excellent. There are seventeen useful NMR problems (^{1}H and ^{13}C), and ten mass spectra to interpret. Overall, the treatment is as good, if not better, than the standard texts of the day: Williams and Fleming (*Spectroscopic Methods in Organic Chemistry*; McGraw-Hill: New York and London, 1973), and Kemp (*Organic Spectroscopy*; Macmillan: London, 1975).

The final part deals with qualitative analysis, and once again the coverage is adequate, rather than extensive as in Vogel; but unlike the latter, IR and NMR data are interspersed to show how modern spectroscopic methods and wet analysis can go hand-in-hand. The book concludes with a section on use of the research literature. Throughout the book there are good reading references, and it deserves to become a sort of bible for undergraduates taking courses in experimental organic chemistry; but it probably will not achieve this exalted position, as at £10.35 for a paperback, there are cheaper alternatives.

One of these is by W. Kemp (*Qualitative Organic Analysis*), who has successfully integrated wet analysis and modern spectroscopic techniques, but the coverage is not quite so comprehensive as that of Pasto and Johnson. The tables of derivatives are, however, marginally more extensive. The section on spectroscopic methods is much poorer, and includes only the bare essentials of each technique. The aim of the book is nonetheless realised, in that it shows qualitative analysis as a vehicle for learning functional group chemistry. On balance, a chemistry undergraduate would probably do better to buy Pasto and Johnson, whereas ancillary students should find Kemp's book adequate for their needs.

The fourth book, *An Introduction to Organic Chemistry* by J. Carnduff, seeks to present organic chemistry for advanced level school students, from an electronic point of view. Thus the standard reactions of organic compounds are discussed with reference to the fate of the electrons involved. This is a refreshing departure from the norm, as most advanced level school texts seem afraid to include mechanisms and curly arrows. There are seven chapters which cover the fundamentals: 'electron accounting', nomenclature, stereochemistry (including chirality — perhaps a bit ambitious at this level), electronegativity, delocalisation, and classification of reaction types. This is accomplished very effectively, and is followed by chapters on organic compounds, including a useful chapter on organometallic species, as well as the usual list from hydrocarbons to carbonyl compounds by way of alcohols and amines. The section on aromatic chemistry is particularly good. Problems appear at the end of each chapter, with answers at the end of the following one. The final chapter summarises what has been said about ionic reactions. This is a book full of good basic organic chemistry presented in a modern (mechanistic) fashion, and schools will probably buy a cheaper paperback version. My one reservation is the virtual absence of examples showing the industrial and biological relevance of organic chemistry. The Nuffield advanced level books go to the other extreme, with almost total exclusion of mechanism. Surely, a compromise can be reached — perhaps next year? □

John Mann is a Lecturer in Organic Chemistry at the University of Reading, UK.

Fluid mechanics

T.N. Stevenson

Fluid Mechanics. By H.C. Lowe. Pp.228. (Macmillan: London, 1979.) Paperback £3.95.

FIRST-YEAR engineering courses in fluid mechanics are chosen from a vast range of topics. The material found in these courses would fill many volumes, and consequently any one volume of this size is unlikely to be adequate for any one course.

Each chapter in the book includes a short description of the physics and a cursory look at the theory for a particular topic. This is followed by a number of examples and specimen solutions. Some of the examples rely on the theory in this or earlier chapters, but most of them require a much deeper understanding of the subject. Questions are taken from the examinations of the North Staffordshire Polytechnic and the Council of Engineering Institutions. The author knows the syllabus for these courses and has made the approximations expected in those examinations. For the benefit of other students the author could have indicated how more accurate solutions could be obtained to some of the problems.

The book is written in note form with some of the symbols incomplete due to poor type. At least two of the examples have omissions which make them dimensionally incorrect and the vector notation used is not always correct. Some partial derivatives have been typed as total derivatives. The sections on dimensional analysis, wakes, vortex shedding, and on turbulence are misleading. The explanation of Buckingham's π theorem is incomplete and the definition of laminar flow is wrong.

There are scores of books covering parts of first year undergraduate courses in fluid mechanics. Probably not one of these covers exactly the same topics as this text. There is an interesting set of examples in the book. However, in view of the omissions and errors in the explanation of the physics involved, I cannot recommend the book to students. □

T.N. Stevenson is Senior Lecturer in the Department of the Mechanics of Fluids, Honours School of Aeronautical Engineering, University of Manchester, UK.

Classical mechanics

J.W. Humberston

Intermediate Classical Mechanics. By J. Norwood, Jr. Pp.417. (Prentice-Hall International: Hemel Hempstead, UK, 1979.) £14.30.

THE author's justification for writing another undergraduate text on classical mechanics is his belief that the subject should not only be concerned with particles and rigid bodies, but also with many body systems. He has therefore included chapters on elastic bodies, statistical mechanics and fluid mechanics in addition to the usual topics contained in books on classical mechanics. Some of the topics in these chapters are occasionally discussed in mechanics books at this level (for example, *Mechanics* by K.R. Symon), but others, such as plasma physics and hydromagnetic waves, are not. A chapter on relativity theory is also included which gives a rather superficial account of special relativity and only a very brief introduction to general relativity. Several short problems are set throughout the book, but no solutions are given.

The general level of presentation is somewhat higher than is usual for a first year course in mechanics in a British University, although anyone who has taken such a course should have little difficulty understanding most parts of the book. It is clearly written and very well produced and seems to contain very few misprints or errors. One rather unfortunate example of the latter, however, occurs in the discussion of Kepler's laws of planetary motion. The author states, and claims to prove, that the second law, the constancy of the areal velocity, is only true for an attractive inverse square law of force; it is, of course, true for any central force, being a direct consequence of the conservation of angular momentum. □

J.W. Humberston is a Lecturer in Physics in the Department of Physics and Astronomy at University College London, UK.

Statistics and experimental design in psychology

Donald Laming

The Numbers Game. By J.G. Snodgrass. Pp.467. (Oxford University Press: Oxford, 1979.) £5.95. *Experimenting in Psychology.* By R. Gottsdanker. Pp.352. (Prentice-Hall: Hemel Hempstead, UK, 1979.) £9.45.

IN teaching statistics and experimental design to psychology students there is always the problem of maintaining the students' interest. Here are two very different approaches to this problem.

The Numbers Game is a conventionally ordered introductory text. It begins with four chapters on descriptive statistics and then proceeds to an exposition of the standard normal-variate tests; non-parametric procedures are presented in the final three chapters. The writing of individual chapters reflects a great deal of thought and experience in teaching students who may have but little mathematical background. The presentation is conceptually oriented, with important mathematical arguments placed in supplements at the ends of chapters, and the concepts are illustrated with examples. In its concern for communicating with the student *The Numbers Game* is to be commended. But, because of the conventional ordering of the material, the student must work as far as chapter 10 before he is able to appreciate in its entirety even the simplest experiment. As Gottsdanker puts it in his preface to *Experimenting in Psychology:* " . . . to treat various "topics", such as *measures of behavior, subjects, experimental designs, and treatment of data* in separate chapters. When that is done, there can be no comprehensive knowledge about any kind of experiment until the last chapter is covered.".

Experimenting in Psychology employs a completely different approach. It is organised around a graded sequence of example experiments. These experiments are not used to illustrate previously stated principles (as in *The Numbers Game);* rather, they "carry" the exposition. Each experiment presents a practical problem which is worked through in the text, and the solution to this problem exemplifies the principle which the author wishes to present. In the early chapters the experiments are necessarily simple, mostly concerned with applied problems. Regrettably some of these are artificial, made-up examples, which are never as interesting as real ones. But in the later chapters dealing with the more complex problems of design, the experiments are all recently published examples drawn from a wide range of psychological subject matter. The reader thereby obtains some appreciation of the complexity of experiment needed in contemporary research and of why its design is important; in addition, as a by-product, the book encourages a catholic interest in scientific psychology.

Of these two books, I am confident that the second will hold the students' interest the more readily. From the outset it demonstrates the importance of experimental design in psychological research and provides the student with a motive for studying its technicalities. Dr Gottsdanker is to be commended for developing this new approach. But, at the same time, he has bent over backwards trying not to alienate those with a distaste for mathematics. The main text is entirely devoid of algebra and only a very little statistical theory is included, set in a series of statistical supplements placed at the end of each chapter. The author has, by intention, written a book on experimental design alone, virtually without statistics. But the criterion of good experimental design is that the data can readily be analysed with respect to the questions of interest; so that the possibilities for design are dominated by the analytical techniques. Dr Gottsdanker could have slipped in much more about data analysis than he has; it is a pity — it would have made the book more widely useful.

There remains the possibility that these two books, so very different in approach, might actually complement each other and be successfully used in tandem. They will provide an attractive combination for any psychologist who teaches chiefly the use of normal-variate procedures. ☐

Donald Laming is a Lecturer in Experimental Psychology at the University of Cambridge, UK.

Establishing psychology

O. L. Zangwill

Introduction to Psychology. By E. Hilgard, R. A. Atkinson and R. C. Atkinson. Seventh edition. Pp. 653. (Harcourt Brace Jovanovich: New York and London, 1979.) Hardback £10.35; paperback £7.75. *Basic Writings in the History of Psychology.* By R. I. Watson. Pp. 420. (Oxford University Press: New York and Oxford, 1979.) £5.95. *Psychology Survey, No. 2.* Edited by K. Connolly. Pp. 288. (George Allen and Unwin: London and Boston, 1979.) Hardback £7.50; paperback £3.95. *Brain Behaviour and Evolution.* Edited by D. A. Oakley and H.C. Plotkin. Pp.237. (Methuen: London, 1979.) Hardback £9; paperback £4.95.

THESE four books, two British and two American, are all concerned in one way or another with the teaching of psychology at University level. It is, however, virtually impossible to compare them directly on account of the very real differences that exist between the British and American systems of higher education. While the American texts are designed to meet the needs of College students taking an introductory course in psychology who may or may not wish to proceed further with the subject, the British texts are intended for second- or third-year students taking psychology as a main subject in an Honours Degree course in a British university. Although the teaching of psychology in Britain makes extensive use of American texts and journals, it cannot be said that either of the two American volumes under review is likely to prove obviously appropriate for use in this country. This is not, however, to say that they are both without educational value or do not merit sympathetic consideration.

The Hilgard, Atkinson and Atkinson text, originally published in 1953 and already fairly well known in Britain, now appears in its seventh edition. As in the earlier editions, the authors explain that they have tried to write an introductory text for students who in their experience are more likely to be interested in what they consider to be "relevant to their lives, futures and the problems confronting society" than in the preoccupations of professional psychologists. This fashionable demand for "relevance" they have attempted to meet "without sacrifice of scientific rigour or scholarship". In fact, the book consists very largely of the standard stuff of contemporary academic psychology enlivened by some reference to topics such as hypnosis, psychotherapy and the effects of psychotropic drugs, which students are presumably expected to deem "relevant". In spite of this somewhat patronising attitude to supposed student interests, it must be said that the authors have produced an attractive text that presents the subject matter of experimental psychology intelligently and well. It may be surmised that it owes much to Dr Hilgard's admirable good sense and solid judgement and to his fortunate choice of collaborators.

Dr Watson's compilation of *Basic Writings in the History of Psychology* at all events makes no compromise with "relevance", as it might be supposed that few American students of introductory psychology would dissent from the celebrated judgement of Henry Ford. The book consists of some fifty extracts from the writings of assorted philosophers and scientists, including Descartes, Locke and Helmholtz, who may be said to have laid the groundwork for the evolution of psychology as a science. It also contains extracts from the work of some thirty leading psychologists of the nineteenth and early twentieth centuries, mainly German and American although a few British. In his selection, Dr Watson seems to have been much influenced by E. G. Boring's views and follows closely the judgements expressed in his well known *History of Experimental Psychology*. As a result neither French nor Russian psychologists (with the exception of Pavlov, who would have hated to be called a psychologist) find inclusion.

While one may agree with Dr Watson that historical knowledge is of educational value, one may doubt whether the method he has chosen to represent it is a satisfactory one. Indeed it would seem to be modelled more upon *The Readers' Digest* than upon any serious contribution to historical scholarship. Nonetheless, there is just a hope that it might inspire an exceptional student to delve into some of the original sources. It is also exceptionally cheap by today's standards.

Let us now turn to the two British productions. *Psychology Survey, No. 2,* the second volume in a new series, follows closely the pattern established by Professor Brian Foss, who edited the first. It consists of fifteen chapters, each dealing with a single issue or area of inquiry in contemporary psychology. The (very varied) topics have been chosen by Professor Connolly on the grounds of their timeliness and promise on the one hand and the fact that their authors are personally engaged in research in the relevant area on the other. These chapters have no explicit connecting link and may be thought to illustrate well the late Professor Gilbert Ryle's view that psychology is less a science than a consortium of inquiries and techniques that neither has, nor needs, a logically trim statement of programme. Nonetheless, the editor clearly hopes that his patchwork quilt will provide both stimulation and variety. In this, he is unlikely to be disappointed.

The individual contributions to this book vary very considerably in their range of coverage. Some deal with large areas of the subject as, for example, human engineering or psychopharmacology; others with special issues or topics, such as the theory of colour vision or motor activity mutants of *Drosophila*. In (almost) all cases, however, the authors clearly know what they are talking about and express themselves lucidly and well. In particular, there is a merciful absence of jargon. Like its predecessor, this book may be expected to receive a warm welcome from teachers of psychology and their students.

Lastly we have *Brain, Behaviour and Evolution,* a collection of longish essays expressly compiled to provide students of psychology or the social sciences lacking a background in the natural sciences with some understanding of evolutionary biology. The chapters are of two types, the first four providing basic information about the anatomy of the nervous system, the evolution and genetics of behaviour, brain—behaviour relationships and neurochemistry in relation to evolution. The next five chapters are concerned with more specialised issues, including the evolution and functions of sleep, the relationship of brain size to intelligence (this is a particularly thoughtful and scholarly survey) and the ostensible functional asymmetry of the two cerebral hemispheres in man. To this last chapter Dr Roger Sperry appends a brief afterword on consciousness.

This book is on the whole well done and will undoubtedly be of help to the not inconsiderable number of students to whom it is directed. From an educational point of view, however, it must be insisted that such a book is no substitute for a basic grounding in the established biological sciences and one may well doubt the wisdom of allowing candidates to proceed to degrees in psychology or behavioural science without some previous grounding in the biological or pre-clinical sciences. If this should become an accepted convention, university departments of psychology would of course attract far fewer people than at present and staff and resources would correspondingly diminish. Nonetheless, the quality of the product might well be higher and the prospects for the subject brighter. Psychology would then have the chance to establish itself firmly in the consortium of biological sciences. ☐

O. L. Zangwill is Professor of Psychology at the University of Cambridge, UK.

For the newcomer to nuclear physics

Daphne F. Jackson

Theoretical Nuclear Physics. By J. M. Blatt and V. F. Weisskopf. Pp. 864. (Springer: New York, Berlin and Heidelberg, 1979.) DM64; $35.20.

THIS book was first published as a postgraduate textbook in 1952, twenty years after the experimental discovery of the neutron. Before its publication, newcomers to the study of nuclear physics would probably have used review articles published in the 1930s in *Reviews of Modern Physics* and *Handbuch der Physik* as their introduction to the subject, together with the more descriptive book by Bethe and Morrison.

Blatt and Weisskopf set out to give a complete presentation of the theoretical concepts and considerations which must form part of any theory of nuclear properties and of theoretical techniques which should be used in the analysis and correlation of experimental data. The latter aspect was of particular importance because nuclear physics at that time was in much the same position as atomic physics some thirty to forty years earlier, with a substantial accumulation of spectroscopic information and low energy scattering data but no means of deriving the behaviour of nuclear forces or the properties of nuclei from more fundamental sources.

The authors began at the beginning by discussing the constituents of nuclei, the stability of nuclei, and the significance of the behaviour of the binding energy per nucleon as a function of mass number. They made the assumption that non-relativistic quantum mechanics could be applied to nuclei and proceeded to discuss the excitation of nuclear states and the implications of quantum statistics for nuclear systems. These are all topics which have now reached well down into the undergraduate syllabus for physics students.

The major sections of the book which deal with two-body scattering at low energies and the basic character of the nuclear force and with the general theory of low energy nuclear scattering and reactions, were of great importance when first published and remain very valuable. It is remarkable that much of the notation and many of the illustrations have been carried on into later books by other authors. This confirms the success that Blatt and Weisskopf had in achieving their aim of making the subject understandable to readers equipped with a reasonable background in quantum mechanics. The section of the book dealing with the interaction of nuclei with electromagnetic radiation and the appendix on multipole radiation are outstanding.

The chapter on β-decay remains useful while that on α-decay is rather meagre. Fission is not covered in any detail because much of the relevant information was still classified at the time of writing. From the point of view of the modern reader, the least satisfactory sections of the book are those concerned with the interpretation of nuclear spectroscopic data in terms of nuclear models. When the book was started the shell model had only just emerged and it was nearly ten years later that Weisskopf exposed the important role of the exclusion principle in limiting two-body collisions of the bound nucleons and so making possible the long mean-free-paths required for the existence of independent particle motion. It then became possible to understand how the repeated influence of the residual interactions not included in the averaged potential of the shell model could lead to the formation of the compound nucleus. The addition of a short appendix covering this point would have helped new readers to avoid unnecessary confusion.

The book inevitably contains little discussion of reactions above 20 MeV and it is rather amusing to see energies between 10 and 50 MeV classified as "very high energies" and those above 50 MeV classified as "ultra high energies".

It is open to question whether the re-issue of a book which was written nearly thirty years ago, without any revision or even up-to-date commentary in footnotes and appendices, provides a real service to nuclear physicists. The book still provides a very good introduction to the theoretical techniques of low energy nuclear physics and could usefully serve as a background reader for a first major course on nuclear theory. The book would be of little further use to postgraduates working on nuclear structure theory or direct reactions but should remain of some value to experimentalists working on very low energy reactions and electromagnetic interactions. Indeed, the book might now serve as a foundation for studies in applied nuclear physics.

From a less utilitarian standpoint, there are strong reasons for congratulating the new publishers for keeping this major work in print. It is a classic example of how to write a textbook in a newly developing field. The style is lucid and the authors were capable of being both imaginatively descriptive and searchingly critical. The mathematical formalism has an elegant, uncluttered appearance. This book is attractive to an extent unsurpassed by later works of comparable scientific complexity. □

Daphne F. Jackson is Professor of Physics at the University of Surrey, UK.

Atomic, nuclear and elementary particle physics

P.G. Murphy

The Structure of Matter: An Introduction to Atomic, Nuclear and Particle Physics. By R.M. Turnbull. Pp.266. (Blackie: Glasgow and London, 1979.) Paperback £7.95.

THIS book contains a concise account of atomic, nuclear and elementary particle physics, for the early years of an undergraduate course in science. It is written at a fairly elementary level compared with most of the numerous texts of this kind. It gives more space than is usual to elementary particles, justified by the inclusion of very recent developments of fundamental significance. Most of the book contains traditional material treated in an orthodox manner. It should therefore reach a very high standard to justify its addition to our libraries, or the expenditure of a large sum for a slim volume. Let us therefore look at the treatment of one of the most important parts of the subject. On page 96 we are told that "Schrödinger postulated a wave equation . . .", followed in the next sentence by equation 8.5, which is a wave equation; nothing is said to prevent the innocent student from believing that it is the Schrödinger equation. Unfortunately it is not (except possibly the relativistic form for a massless particle). The true Schrödinger equation does appear, two pages later, as a result of some unexplained manipulations on a harmonic wave. Then we are told that it is "known as the time-dependent form since . . . V is in general a function of both position and time". This is wrong; the phrase refers to the wave function, not to the potential (which could well be zero). The next sentence says "Wave-particle duality is incorporated . . . since it . . . contains a potential energy term describing the interaction of a particle with its environment". This duality is inherent in the interpretation of the wave function and has nothing to do with the potential.

Tutors who have to eliminate these ideas will wish that this book had not been published. I have described only the worst faults I have found. In other parts we find an inadequate treatment of the uncertainty principle, a long section on Wilson-Sommerfeld orbits which is an unnecessary difficult subject, again with misleading and inadequate explanations (it leaves us thinking that Sommerfeld's relativistic term explains fine structure correctly), and other inaccuracies. This book cannot be recommended. □

P.G. Murphy is Professor of Physics at the University of Manchester, UK.

Developments in physics

Leonardo Castillejo

The Structure of Matter. By S. Gasiorowicz. Pp.525. (Addison-Wesley: London, 1979.) £16.50.

IN 1933 the publication of Max Born's classical book *Atomic Physics* set a standard for a comprehensive yet simple introduction to the new ideas and developments in physics. Since that time the subject has grown so large that most authors choose to restrict themselves to one field such as relativity or quantum mechanics, solid state or statistical physics, and to provide within the chosen topic more mathematical details and worked examples to enable the student, not only to grasp the new ideas, but also to calculate things for himself.

In this textbook on *The Structure of Matter* Dr Gasiorowicz has combined both these aims. He includes all the topics listed above, together with a wide range of simple applications and illustrations in related fields. The mathematical requirements are few; basic calculus and the use of matrices. The physical arguments are presented very clearly and followed up with explicit calculations, often on a simple model, so that all the details can be worked out. The crucial features which generalise to the real problem are then clearly emphasised.

The book is divided into six parts. The first covers relativity. This is an excellent and lucid exposition of the essential ideas and provides a working knowledge of Lorentz transformations, relativistic kinematics and even some transformations of electromagnetic fields. The second section on statistical physics is based on a mixture of statistical distribution and kinematic theory, derives the Boltzmann distribution, with some applications, and discusses black-body radiation. I was unhappy that the concept of temperature, which is so fundamental, was introduced rather superficially in terms of the ideal gas law.

There follow three sections on quantum mechanics; the first explaining the early models, then a self-contained and beautifully clear section formulating quantum mechanics up to the harmonic oscillator and finally a more advanced section including angular momentum, the hydrogen atom and spin. In the final part of the book the methods of quantum theory, statistical physics and relativity are used to describe and explain a broad spectrum of physical phenomena. The examples are well chosen to give an overview of modern physics as well as to provide opportunities to extend calculational techniques. For example, the discussion of electromagnetic transitions and selection rules also provides a derivation of time dependent perturbation theory, and the calculations of specific heats of phonons and electrons provide an introduction to Bose and Fermi-Dirac statistics. This last part introduces the reader to atomic and molecular physics, solid state, nuclear physics and elementary particles. The latter topic is treated in more detail than the others and ends with a discussion of quarks, colour and charm.

This book is exciting to read, yet designed for instruction and as a course text. There are many good examples at the end of each chapter. It is one of the best introductory textbooks to modern physics which I have seen and it deserves to be widely used. □

Leonardo Castillejo is Professor of Physics at University College London, UK.

Analytical chemistry

T.S. West

Analytical Chemistry. By D.J. Pietrzyk and C.W. Frank. Second edition. Pp.700. (Academic: New York and London, 1979.) $16.50.

A DETAILED examination of the text of this book shows that in many respects it is rather like the legendary 'curate's egg'. At first sight there are many excellent features of planning and intention such as material on sampling, choice of analytical method, literature on analytical chemistry, units, standards, preliminary operations, and so on; but, unfortunately, these are vitiated by lack of penetration into the subject or by a loose approach. So, what looks promising when one first looks at the list of contents, turns out to be little more than a run-of-the-mill treatment. In the sense that there are references to the edicts or regulations of bodies such as the FDA, EPA, APHA, ASTM, and so on, which is, of course, perfectly appropriate for the student mass market in the USA, the book is nevertheless a US national rather than an international publication.

It is considerably less welcome, however, to find the use of the 'Formality concept' predominating in the book and, even though lip service is paid to SI, it has to be said that 0.1F H_3PO_4 is more inconsistent and confusing than continued use of 'ml', 'litre', and so on, which are, at least, still in common use throughout the world. It is also noticeable that principal references are made almost exclusively to American papers and books and, indeed, that there are very few references to the original literature throughout the text. Students who use this text are consequently likely to receive little training or introduction to a concept which the authors apparently value highly. According to page 18: "The literature of analytical chemistry, as in any other scientific area, is the life blood. The books provide the newcomer with the required background while the journals provide a vehicle for critical discussion about the old and the new.". Yet on the very next page one of the leading international journals is incorrectly given.

The subject matter is treated fairly fundamentally and goes into the conventional techniques of gravimetry, titrimetry (given as "volumetry"), fairly well. The treatment of optical procedures such as flame spectrometry (still showing detailed diagrams of a total consumption burner), atomic absorption and fluorescence spectroscopy is so rudimentary that it is almost without value: similarly polarography. The separation section on ion exchange and chromatography is more satisfactory; but the solvent extraction chapter, which includes a solitary incomplete reference, is also lacking in penetration.

This is not a book that I would recommend with any degree of confidence.

T.S. West is Director of the Macaulay Institute for Soil Research, Craigiebuckler, UK.

Solid-state chemistry

J.N. Murrell

Structure and Bonding in Solid State Chemistry. By M.F.C. Ladd. Pp.326. (Wiley: New York and Chichester, UK, 1979.) £16.50.

THIS is a welcome book on solid-state chemistry, for I am sure that the subject gets short treatment in most chemistry courses. The difficulty faced by an author in this field is to decide what to include and what to omit. The subject cannot be taught without reference to gas phase molecular structure and to chemical bonding theory but these are topics adequately covered in other monographs. If this background material is omitted then I suppose that there is the danger that the book will either be rather thin or will have to include detail which is too specialised for an undergraduate text.

Dr Ladd has chosen to include a substantial amount of background material on basic quantum mechanics and the theory of the covalent bond (over 70 pages in all). He also includes 10 pages of appendices covering the thermodynamics of electrolyte solutions, required, as far as I can see, only for brief discussion of the solubility of ionic compounds. My own inclination would have been to direct the reader to other books for these topics because I think it diverts attention from the main direction of the text.

Chapter 1 is titled "Preamble" and gives an introduction to the structure of solids. In contrast to my view expressed above I found this section surprisingly thin on the experimental and theoretical aspects of diffraction. For example, I found no reference to neutron diffraction and its relevance to the position of hydrogen atoms in solids. The book would certainly not be adequate to cover the material necessary for undergraduate chemistry teaching of diffraction.

Chapter 2 covers ionic crystals comprehensively, reflecting one of Dr Ladd's research interests. There is a short section on colour centres. Chapter 3 deals with covalent compounds but only one page out of seventy deals with covalent solids directly (diamond, for example), the rest being used for the background material already referred to.

Chapter 4 is titled "Van der Waals' Compounds" and contains a brief description of intermolecular forces and their relevance to inert gas solids, organic molecular solids and donor-acceptor complexes. Chapter 5 covers metallic compounds and contains an elementary treatment of band theory; the free-electron model, Brillouin zones and Bloch theory. Each chapter presents a set of problems and solutions are given at the end of the book.

In summary, I feel that the balance of the book is not ideal but it should still be very useful reading for students of chemistry and chemical physics. □

J.N. Murrell is Professor and Dean of the School of Molecular Sciences, University of Sussex, Brighton, UK.

Astronomy textbooks

David W. Hughes

The Solar System. By J.A. Wood. Pp.196. (Prentice-Hall International: Hemel Hempstead, UK, 1979.) £5.05. *Galaxies: Structure and Evolution.* By R.J. Taylor. Pp.203. (Taylor and Francis Wykeham Publications: London and Basingstoke, 1979.) Paperback £4.50. *The Astrolabe.* By H.N. Saunders. Pp.12. (Science Studio: Oxford, 1979.) £4.75. *Projects and Demonstrations in Astronomy.* By D. Tattersfield. Pp.331. (Stanley Thornes: Cheltenham, UK, 1979.) *Astronomy: Activities and Experiments.* By L.J. Kelsey, D.B. Hoff and J.S. Neff. Pp.187. (Kendall/Hunt: Dubuque, Iowa, 1979.) *Activities in Astronomy.* By D.B. Hoff, L.J. Kelsey and J.S. Neff. Pp.142. (Kendall/Hunt: Dubuque, Iowa, 1979.) *Astronomy: From the Earth to the Universe.* By J.M. Pasachoff. Pp.200. (W.B. Saunders: Philadelphia, London, Toronto, 1979.) (Plus *Teachers Guide.*) *Exploring the Cosmos.* By L. Berman and J.C. Evans. Second edition. Pp.89. (Little, Brown: Boston and Toronto, 1979.) (Plus *Instructor's Manual.*) *The Macmillan Dictionary of Astronomy.* By V. Illingworth. Pp.378. (Macmillan: London and Basingstoke, 1979.) £8.95.

THIS year's crop of astronomy textbooks can be easily sorted into three groups which, for want of better, can be labelled advanced, experimental and simple.

Two books fall into the advanced section; both are on specific astronomical topics and both are aimed at the second- and third-year university undergraduate. Both are excellent in their own way and both are extremely good value for money. The first is *The Solar System* by John A. Wood, an ideal introduction for all astronomy, geophysics and physics students. Wood had an extremely difficult job in front of him — express in about 50,000 words and 125 figures what you think is of major importance in the Solar System. Now one easy way out is to isolate the planets from the Sun and the neighbouring stars in the Galaxy. Wood didn't do this, thank goodness, and this makes the book even more praiseworthy. He also decided to discuss, chapter by chapter, the unifying features of planets. So we don't get a chapter on each and an insulation of our knowledge of a single planet from the overall picture. Wood considers broad topics, the motions of planets and their interrelations, the surfaces and their evolution, planetary interiors and atmospheres, rocks from space (meteorites and lunar samples), the Sun, solar evolution and the origin of the elements and finally the origin of the Solar System. This book is going to be a firm favourite in universities for years to come. Maybe in the next edition Wood could help the lecturer out when it comes to tutorial and exam time by including a set of questions. Also the suggestions for further reading are a bit dated.

The second advanced book is *Galaxies: Structure and Evolution* by R.J. Tayler, a new title in the excellent *Wykeham Science Series.* Despite their intended aim — to bridge the gap between school and university studies — this book is again at mainstream second- and third-year university level. It is an excellent companion to Tayler's other two books in the series, *The Stars: Their Structure and Evolution* and *The Origin of the Chemical Elements.*

Galaxies are getting more and more popular in astronomy possibly because the number of known galaxies is increasing considerably as telescope instrumentation becomes more sophisticated. I never cease to be amazed at the statistic that there are about as many galaxies in the Universe as there are stars in our own Galaxy. Tayler doesn't cut corners in his book. Galactic properties are discussed with physical and mathematical precision. Considerable emphasis is given to the one galaxy that has been observed well, the one we are in, and there are chapters on observational results, stellar dynamics and the interstellar medium. Careful consideration is also given to the problems of estimating galactic mass and size and assessing the effects of chemical evolution. Other chapters deal with the different classes of galaxies and the origin and evolution of galaxies and the Universe.

This book will make galactic astronomy more accessible to many students and Professor Tayler is to be well congratulated for this.

Finally in the advanced section we have *The Astrolabe* by H.N. Saunders, a plastic folder which contains a 12-page booklet and an assembled, 14.5-cm diameter, white and clear plastic astrolabe. The astrolabe was invented in Alexandria around 400 AD and was used by astronomers for over 1,200 years. It gives the times of rising and setting of the Sun and certain specific stars throughout the year and their positions in the sky (that is, altitude and azimuth) at any time of the day and night. The astrolabe in the Saunders package has been designed for use at latitude 50° North but will still give useful answers within two degrees or so of this. If you want to know how astrolabes work and wish to become acquainted with such terms as retes, rules, plates, tympans, almucantars, heliacal risings and alidades this is just for you. There are 32 stars on the plate and the booklet is clearly written and contains many worked examples of astrolabe uses. The Saunders instrument is well made, durable and will stand up to a considerable amount of student handling. It would provide the basis of a very reasonable laboratory experiment for the more historically minded. A brief comparison can be made with another astrolabe package. In 1974 Roderick S. Webster produced an 8¾″ diameter, six section astrolabe kit, printed on gold cardboard and die cut so that the sections press out and don't have to be cut out (in 1974 it was $18 and obtainable from Paul MacAlister and Associates, Box 157, Lake Bluff, Illinois 60044). Six plates were included, for latitudes 30, 36, 42, 49, 52 and 56° North. It was decorated to conform with Renaissance practice. Webster's astrolabe looks more like 'museum' examples but is much more fragile than the smaller plastic Saunders one. Webster's booklet did stress the historical aspect more and had an excellent bibliography.

Let us now turn to the experimental aspects of astronomy. Like many other sciences, astronomy is both practical and theoretical and the majority of students studying the subject spend a considerable

---

Particle physics

Norman Dombey

Elementary Particle Physics. By D.C. Cheng and G.K. O'Neill. Pp. 423. (Addison-Wesley: Reading, Massachusetts, 1980.) $29.50.

THIS is a very nice brief introductory text to the subject with roughly half devoted to electromagnetic and weak interactions and half to strong interactions. It is up to date: not only does charm enter together with strangeness in Chapter 1 but even the SLAC experiment of summer 1978 showing parity violation in electron scattering is quoted.

Nevertheless, the book is solid rather than fashionable and in spirit belongs to the late 1960s and early 1970s (this is not meant as a criticism) rather than the present. C,P and T-invariance; SU(3), (4) and (6); form-factors and structure functions; quarks and partons; dispersion relations and Regge Poles are all treated in some depth. Gauge theories are mentioned but not explained; so is the unification of weak and electromagnetic interactions; but QCD perhaps wisely is absent.

I will certainly recommend the book to my students, both undergraduate and graduate. There are, however, several errors in the text of the edition I received which need correcting. ☐

Norman Dombey is Reader in Physics at the University of Sussex, Brighton, UK.

A shining arc of the Sun's chromosphere (taken from *The Illustrated Encyclopaedia of Astronomy and Space;* Macmillan: London)

time doing observational and laboratory assignments. At my university the first-year students have to do 15 over a period of two terms. When it comes to preparing the instruction sheets for these projects I dip deeply into a whole range of books and manuals and when new books on astronomical experiments come onto the market I must admit that I buy them indiscriminately. Each book invariably contains a few good ideas usually distilled from the painful experience of the writer who has a similar job of organising laboratory and observing work for a large class of students. The British student doesn't usually expect to have to buy a laboratory manual. This is often not the case in America.

Projects and Demonstrations in Astronomy by D. Tattersfield is written for the overcast astronomer, and the author offers a range of projects that can be done indoors using only the most modest equipment and a modicum of mathematical skill. Many of these projects would be suitable for advanced level (about seventeen years old) students. In reading the book I came across many good ideas but too few projects which I would adopt in their entirety. I thought that too much use had been made of line drawings of photographic plates and spectra. This gives the student too little impression of the problems of measuring spectral lines on real plates. Often in astronomical spectroscopy the apparent width of the line varies as one moves along it. Also when it comes to measuring the distances between star images on plates the images are not points but diffuse and sometimes irregular disks. Reproductions of the original photographs can be produced fairly easily, as has been shown in the excellent series of laboratory exercises published by Sky Publishing Corporation from their journal *Sky and Telescope.* Tattersfield does this for the North American Nebula and I think should have done it more often.

More emphasis should also have been given to the errors in the quantities obtained from the graphical and numerical calculations. A student acquainted with the mathematics required to do these exercises should also know about standard deviation and the problems of fitting linear functions to small sets of data. In this context I am very worried when students are encouraged to plot the logarithm of the mass against the absolute magnitude for Sirius A and the Sun and then told "Draw a straight line through the two points on the graph. This is the mass–luminosity relationship." The author in the extensive "Solutions" section at the end of the book then adds data points for Capella A and Krüger 60A and inserts a much more reasonable line. I think I will use Tattersfield's book quite a bit, but only as a jumping off point, and with caution.

Astronomy: Activities and Experiments by Linda J. Kelsey, Darrel B. Hoff and John S. Neff is a revised and updated edition of the original 1971 manual which was published by the University of Iowa. After reading this book, two points become very clear. Firstly that the authors have had years of experience in the job of making laboratory exercises interesting and exciting for first-year university students and in dealing with the general range of student problems. Secondly they are first rate experimental scientists who know well the joys and frustrations of experimentation and the disciplines that must be developed when it comes to analysing and presenting the results. They end the brief section of suggestions for writing laboratory reports with the curt statement "Think before you write". Throughout the book it is obvious that the authors did just that. The book contains forty exercises, fairly evenly split between telescopes and observational techniques, coordinate systems and time, Earth, Moon and planets and the Sun, stars and galaxies, It is clearly presented, and well illustrated with a host of photographic reproductions. Each experimental text is subdivided into sections labelled purpose, references, introduction, procedure and discussion questions. It is an excellent book and I recommend it very strongly. It has been specifically designed for a two semester astronomy course at American universities but will be of inestimable use to all university, college and upper school teachers.

The book has spawned a baby brother. *Activities in Astronomy* by D.B. Hoff, L.J. Kelsey and J.S. Neff is aimed at the one-semester introductory astronomy student and is a shortened and somewhat simplified version of the previous book, containing only 25 exercises. The standard of presentation is just as good.

Now to the 'simple' books, by which I mean the ones designed for the non-mathematical American arts students market. I have been looking at three this year and these are Jay M. Pasachoff's *Astronomy: From the Earth to the Universe, Exploring the Cosmos* by L. Berman and J.C. Evans, and *New Horizons in Astronomy* by J.C. Brandt and S.P. Maran. *Horizons* and *Cosmos* are both second editions and Pasachoff's book is a slightly more historical version of his *Astronomy Now* which was a shorter version of his *Contemporary Astronomy* which was a shorter and no algebra and trigonometry version of his *University Astronomy . . .*

Where do we go from here? All the books cover the same areas of astronomy and are profusely illustrated with photographs of planets, stars, galaxies, clusters, and so on. If I were a student I would leave the choice of book to my course tutor. He has probably designed his teaching and his approach to astronomy around a specific text. The tests and examinations that must be passed will be based on that specific text. The scholar buys the book, learns the work, passes the exam, gets older and forgets astronomy. But look at it from a different angle. How should astronomy be taught to non-mathematical students? These three books illustrate two basic approaches. One is to treat astronomy as a simple story, which can begin historically, or at the edges of the Universe or at the Earth's surface or with our nearest star the Sun, and to tell the story with the aid of pictures. Pasachoff does this and so do Brandt and Maran. Both books do it well and colourfully, but I found myself time and again asking the question "Is it science?". The second approach is to treat astronomy not as a story, but as a science, a great science, the first science. The author can vary the difficulty of his approach but he never forgets that he is dealing with a science subject, a subject of experiment and hypothesis, of fruitful paths and blind alleys, a subject in which the mysteries of the unknown increase as our knowledge grows. Berman and Evans treat astronomy as a science. If I was teaching American arts majors about astronomy and trying to tell them what it is really all about I would use a book like Berman and Evans' *Exploring the Cosmos.* I would buy this book for some of the line drawings alone. It contains very little mathematics. That which is there can be understood by the most arty of art students given a bit of motivation. J. Robert Oppenheimer said "I believe most strongly in the nobility of this great effort to understand nature". Berman and Evans stress the how of astronomy as opposed to the other authors who spend too long simply describing the what.

Valerie Illingworth has edited *The Macmillan Dictionary of Astronomy* from contributions commissioned from a host of British professional astronomers. Dictionaries can be easily judged by asking two questions. The first is "Is it in?". Ignorance forces you to open the dictionary and the dictionary is only useful if it has an entry on the subject you are looking up. Secondly, "Does this entry tell you what you want to know?". The answer to the first question was "yes". The Macmillan dictionary nearly always had it in. Butler matrix, Bw stars, ylem, YY Orioris stars were all there. I only caught it out by straying into planetary geological features (grabens, horsts, and so on) and I should not have been looking these up in an astronomy dictionary anyway. I answered the second question in the affirmative too. So the conclusion is simple, if you want a good astronomy dictionary get this one. ☐

David W. Hughes is Lecturer in Astronomy and Physics at the University of Sheffield, UK.

Aerospace environment

T.B. Jones

The Upper Atmosphere and Solar-Terrestrial Relations. By J.K. Hargreaves. Pp.298. (Van Nostrand, Reinhold: Wokingham, UK, 1979.) £7.25.

THE launch of the first satellites in the late 1950s stimulated the study of space physics which has expanded rapidly since that time. The Earth's outer environment, or 'near space', is a particularly important and interesting region from both scientific and engineering viewpoints. It is the region where strong interactions with solar radiations and particles occur and where ionised particles can greatly influence man's activities.

Dr Hargreaves' book provides an excellent introduction to the aerospace environment. It is intended primarily for undergraduate use and in this respect it fills an important need, as there are relatively few books available on the subject at this level. The present volume provides a broad picture of the Earth's environment, beginning at the base of the ionosphere and extending outwards to the magnetospheric boundary. The structure and behaviour of the ionosphere and magnetosphere are discussed in detail and these topics form the major part of the book. The interaction of the Sun's emissions with the Earth's environment is of fundamental importance in understanding the behaviour of both the ionosphere and the magnetosphere and full coverage of this subject is included. In particular, a detailed account is given of solar disturbance phenomena and their spectacular consequences in the aerospace environment. Mathematical formulation has been kept to a minimum and is only introduced where essential to the understanding of a particular section. Chapters have been included on experimental techniques and on the engineering significance of the various regions described.

The material is well illustrated throughout and many cross-references have been included. In several cases numerical estimates of the magnitude of various parameters (for example, electric currents and fields) are included which help the reader relate them to his everyday laboratory experience. Copious references to more advanced literature are included at the end of each chapter.

The author has succeeded in presenting an integrated account of the wide range of phenomena which occur in the Earth's outer environment. He has done this in a clear and concise style which makes the book particularly attractive for undergraduate use. The work will also appeal to the more specialised reader who will find it helpful to have the wide range of topics, together with many references to source material, contained in one compact volume. ☐

T.B. Jones is Reader in Physics at the University of Leicester, UK.

Solar energy

D.O. Hall

The Sun. By D.K. McDaniels. Pp.271. (Wiley: New York and Chichester, UK, 1979.) Paperback £6.50.

THIS is a good book and certainly can be recommended as an introductory text for a course on solar energy, but . . . Why is it that so many books, articles, and so forth, on solar energy ignore the most important use of solar energy today, that is, the energy from biomass which daily provides the equivalent of 20 million barrels of oil (equal to USA oil consumption) — probably because such solar energy use mostly occurs in developing countries where it is of crucial importance. But it is not recognised that currently, for example,the USA obtains about 2% and Sweden about 10% of their total energy from biomass. Enough said!

The first three chapters discuss the overall energy problem, although it is heavily biased to the US situation. There are excellent chapters on the Sun and Universe and on solar radiation, and there are also discussions on economics.

The second half of the book describes solar energy applications for heating, cooling and electric power generation. The presentation of principles of operation, and the examples given, are very well thought out and clearly written with good diagrams and figures. The index and references are useful; the problems at the end of each chapter will also be helpful in teaching.

In short, a book to be recommended, as much experience in repeated teaching of a solar energy course to beginners is evident in the presentation. "The emphasis is entirely upon developing a qualitative approach of the subject" — this has been achieved. ☐

D.O. Hall is Professor of Biology of King's College, London, and Chairman of the UK Section of the International Solar Energy Society.

Steady-State Enzyme Kinetics

Stanley Ainsworth

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered. Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation.

M MACMILLAN PRESS

Speech physics

C. J. Darwin

The Physics of Speech. By D. B. Fry. Pp.148. (Cambridge University Press: Cambridge and New York, 1979.) Hardback £9.50; paperback £3.50.

THE study of speech brings together an extraordinary variety of people. There are not just the phoneticians, old and new, transcribing and measuring, training their ears and improving their syntheses, but also a growing number satellites: computer scientists and electrical engineers intent on recognising and synthesising speech automatically, psychologists trying to understand how on earth we all manage to produce and perceive speech at all, speech pathologists helping those who can't and the theoretical linguists, phonologists and beyond, wondering what it all means.

Students in all these fields need to know the fundamentals of speech, but their teaching presents real problems as the engineer's meat is the pathologist's poison. Professor Fry's book is not for engineers. He manages, successfully, to explain the principles of the physics of speech assuming no mathematical ability in his reader (the only equation used is the definition of the decibel, and Fourier is not even mentioned). Nevertheless, all the necessary ideas are presented in a clear if not very sprightly way. Any student who has read the book carefully will understand the notion of a spectrum, appreciate the distinction between a sound source and its subsequent filtering, know what formants are and how to interpret a spectrogram, and will have some rudimentary knowledge of the acoustic cues to the more important phonetic distinctions. There are, of course, minor flaws, but nothing is seriously misleading.

The competition with which Fry's book has to contend is Ladefoged's *Elements of Acoustic Phonetics,* first published in 1962 and still available in paperback from University of Chicago Press for around two dollars. Ladefoged deals with wave analysis at greater length than Fry, illustrating his chapter with many clear diagrams of waves and spectra. Fry, with some justification, neglects the waveform for the spectrum. I suspect that students will find Ladefoged's treatment of this topic more lively than Fry's, and will appreciate his use of fewer words and more diagrams. But Ladefoged spends appreciably less time on actual speech sounds and their underlying production mechanisms, so that, faced with a real spectrogram, his reader would be considerably more baffled than Fry's. □

C. J. Darwin is Reader in Experimental Psychology at the University of Sussex, Brighton, UK.

Variegated manifestations

D. Rosen

Aspects of Biophysics. By W. Hughes. Pp.362. (Wiley: New York and Chichester, UK, 1979.) £11.95. *Biophysical Science.* By E. Ackerman, L.B.M. Ellis and L.E. Williams. Second edition. Pp.634. (Prentice-Hall: Englewood Cliffs, New Jersey, and Hemel Hempstead, UK, 1979.) £18.20.

HUGHES quotes a US National Academy of Sciences study which argues that "the classical subdisciplines of biology [that is, zoology, botany, and so on] are insufficiently instructive as approaches to current understanding and appreciation of life in its varigated [*sic*] manifestations". He uses this as a valid justification for cutting through the range of biological phenomena in an orderly way, with the order determined by those physical phenomena which can be discerned among the biological ones. Ackerman and his co-authors find the subject organised in almost the same sequence as that found by Hughes, but they tackle it in the reverse order. The two books are at just about the same level, textbooks suitable for senior undergraduates or junior graduate students.

The problem of teaching biophysics now is akin to the problem of teaching biochemistry about 50 years ago. Then, the question was whether any students would have the requisite background in chemistry and biology: they were likely to have one but not both. Now, the question is whether they have the background of physics, chemistry and biology: they may well have the first two or the last two, but not all three. The two books considered here both affect, in the enthusiasm of their prefaces, to be appropriate to all classes of readers. In a rough way, however, it may be said that Hughes' book is more suited to the student with the physics-chemistry background and Ackerman's to the student with the biology-chemistry background.

Hughes starts with atoms and molecules and with X-ray diffraction and electron microscopy as the techniques of studying the most elementary parts of living things. He builds upwards. He goes on to describe the physics of proteins and nucleic acids, and then membranes and mitochondria, so leading to physical aspects of cellular function and organic function, and finally to still larger problems of living matter. What I particularly liked in his approach is the way he pushes a numerate, mathematical description into quite elementary accounts of the various topics he deals with, from enzyme action to vision. When the topic itself has a well established mathematical formulation, he takes full advantage of it. In his account of nerve action potentials, for example, he gives brief but adequate derivations of cable theory and the Goldman equation for transmembrane potential before going on to obtain the Hodgkin–Huxley equation. However, this is strictly the physics or physical chemistry of the matter — it comes with only the barest introduction and practically no account of the biological consequences. What I found most distressing in Hughes' book were the misprints and spelling errors, starting on line 3 of page ix, as quoted above, and continuing liberally through the text, striking alike at formula and English word.

Ackerman, Ellis and Williams, in the second edition of a book originally by Ackerman alone, have kept to the plan of the first edition. This combines a partly historical approach with some pedagogical insight into what might tempt a student to give attention to topics in biophysics. The Preface proposes Helmholtz as the originator of biophysics and the first chapters deal with Helmholtz' major interests, hearing and vision. The development is then, as it were, analytic in contrast to Hughes' synthetic approach — the electrically sensitive tissues of the body are considered, leading on to other interaction of cells with physical stimuli, to the physical features of cellular function, to the constituent parts of cells, to biological macromolecules, and to the thermodynamics of biological function. In further contrast to Hughes, Ackerman and his colleagues seem to pull in mathematical explanation with some reluctance when it can hardly be avoided, but prefer a descriptive approach. In their account of nerve action, they give a brief explanation of the Hodgkin–Huxley equation but do not mention cable theory or even the Nernst or Goldman formulae for transmembrane potential. In most other cases, however, they end up by giving much the same physics in much the same mathematical form as is given by Hughes, but accompany it with fuller verbal explanation and better indications of the implications for the study of biology. Ackerman and his co-authors devote the final part of their book, a sixth of the whole text, to biophysical techniques and instrumentation and to medical applications of biophysics. That this section, seventeen years later, is the only one which required major recasting from the first edition, shows how well Ackerman judged his original text; and the second edition preserves the confidence and balance of the first.

From the comments made here it can

perhaps be inferred that these two books, although coming to biophysics in opposite ways, are not complementary: they are just different and each has its virtues. Ackerman is nearly twice as long (and nearly twice as expensive) as Hughes, and so contains lengthier accounts, but nearly all topics found in one also appear in the other. However, though I can imagine few students with a biological background preferring Hughes to Ackerman, there are some students from physics who would prefer Ackerman's approach to that of Hughes. My own preference is marginally in favour of Hughes — I found his style the livelier of the two, his approach to topics more engaged, and the references he provides more interesting and research-oriented. Both books are to be recommended, however, as serious introductions to biophysics, and both are better than the two or three comparable texts which have recently appeared. □

D. Rosen is Head of the Department of Biophysics and Bioengineering at Chelsea College, University of London, UK.

Introductory immunology

George Feinberg

Immunology at a Glance. By J.H.L. Playfair. Pp.35. (Blackwell: Oxford, 1979.) £2.25. *Immunology Simplified.* By T.R. Bowry. (Oxford University Press: Oxford, 1979.) £2.50. *Textbook of Immunology.* By B. Benacerraf and E.R. Unanue. Pp.298. (Williams and Wilkins Company: Baltimore, 1979.) $10.95.

THE only thing these three books have in common is the word "immunology" in their titles. No three authors could have taken three more diversified approaches to their common subject. Yet, this is not to fault any of them, since immunology has become so complex an author must take a calculated decision on how he can best present it to the would-be learner.

J.H.L. Playfair's *Immunology at a Glance* chooses to do it essentially with diagrams (sketches, the author calls them): a set of 34, in fact, which starts with the "Scope of Immunology" and then proceeds stepwise in complement cascade fashion, each diagram 'activating' the next till the "terminal assembly" of three diagrams representing "Altered Immunity". The sequence is logical and each diagram is accompanied by a brief — I would say too brief — explanatory section, as well as a useful listing of definitions.

But the title is misleading. Immunology *at a glance* the book certainly is not. The diagrams are often complex: one picture may be worth a thousand words, but not when it tries to express a 'thousand' ideas. Even with the accompanying explanations, most of the diagrams require a study session rather than a glance. That said, it is a good book, based on a novel approach, but ill-served by its title, which suggests it is a casual book for the beginner. In fact, in his preface the author states "this is not a book for immunologists". I dispute this! I see its greatest potential as an *aide memoire* to the professional immunologist and, especially, to the teacher of immunology, who, more than anyone else, must try to grasp the whole picture. I suggest a more appropriate title for this book would be: "An Atlas of Immunology".

Alas, as in all first editions, some errors have crept in: such as a definition of lysosome which gives the impression the macrophage is its sole source; and the diagram on "Anaphylaxis and Allergy", which has bradykinin emerging as a mediator from the mast cell. I must also note my sorrow at one glaring omission: the failure to give due consideration to the structure and characteristics of antigens, without which there would be no immunology.

The book by T.R. Bowry is antipodean to that of Playfair. *Immunology Simplified* it certainly is; some may feel it is over-simplified. It reduces diagrams to a bare essential and relies, instead, on a narrative-style text to make the immunological feast palatable to the uninitiated. In this it largely succeeds, but — perhaps inevitably — at the sacrifice of any profundity. Without too much effort, it could be transformed into a book of popular immunology for the layman.

But perhaps therein lies its strength: it follows a logically flowing pattern, setting forth the fundamentals in three brief chapters, before ranging over the consequences — good and bad — of the activation of the adaptive immune system. Adding to the sense of simplicity — "extreme simplicity" is the publisher's assessment on the back cover — is the small-page format and the large, open print. This is a book which succeeds in living up to its title; and if it is 'simple' immunology the reader is seeking, he need go no further in his quest.

The last of the trio, Benacerraf and Unanue's *Textbook of Immunology*, comes closest to the traditional idea of a college textbook. With its informal offset lithography it gives the impression of being the original lecture notes of an immunology teacher. Perhaps this is not surprising, as it "was originally organised from the teaching materials . . . (used) as part of the introductory course in immunology of the Harvard Medical School curriculum". The best praise I can give it is that it certainly lives up to the standards one would expect from an institution of Harvard's repute.

Again, we have a type which is large and easy on the eye. This makes the mastering of the wealth of up-to-date information in the book a less formidable prospect. The development of the subject is classical and, to my way of thinking, logical in devoting a whole chapter to a consideration of antigen, before launching into the immune response it induces. Perhaps less logical is the presentation of the complement system long after a series of chapters in which a familiarity with its workings would be useful; but in a book that so elegantly sets out the precepts of immunology, this is mere quibbling. Particularly lucid presentations of complex subjects are the chapters on transplantation biology, immune regulation and immunogenetics. Diagrams are sparse, but clear and pertinent. I found no obvious errors of omission; nor, at a quick reading, any of commission. Pleasing, too, is the short list of both classical and current references appended to each chapter.

So here we have three books collectively catering for a wide variety of tastes and needs. It is for the reader to choose that most suited to his immunological appetite and/or dietary requirements. □

George Feinberg is Director of Studies in Immunology at Chelsea College, London, UK.

Participating in perception

F. W. Campbell

Sensation and Perception. By S. Coen, C. Porac and L. M. Ward. Pp.514. (Academic: New York, San Francisco and London, 1979) Hardback $14.95; £9.75; paperback £6.50.

THIS textbook has several unusual features which make it a particularly useful teaching tool. Firstly, it is extraordinarily well illustrated with numerous clearcut diagrams to distill succinctly the relevant information. To illustrate the properties of colour vision there are also a number of colour plates. One of its strongest features is the Demonstration Boxes, which contain instructions for the reader to undertake numerous simple experiments. For example, pouring out a glass of water reflected in a ladies' hand-mirror. To quote from another Box, "use two white plastic spoons (like those probably available in any campus cafeteria) to produce a Ganzfeld by placing the bowls of the two spoons over each eye as shown in the accompanying figure". Again, sit in your motor car, turn on the radio and start the engine. Change the engine speed and note the effects of the engine noise on the quality and perception of some classical music. This encouragement of the reader to participate does much to deepen their understanding of the text.

To cover the whole range of sensation and perception has required three authors. Yet the style is very uniform and well integrated. Indeed, another unusual feature is to intermingle the different sensations rather than segregating each one to its individual section.

For the newcomer there is a comprehensive glossary of specialised terms, words and units. There are 23 pages of references containing some 500 scientific papers to enable the reader to study in depth any particular point. There is also a good author and subject index.

Recent advances are often handled by inserting a Special Topic, such as, How to Calculate d-prime, or, What is the Neural Response? or, The Modulation Transfer Function. This enables the newcomer to skip these special points on his first reading.

The publishers are to be congratulated on producing such an attractive volume for a remarkably low price. ☐

F. W. Campbell is Reader in Neurosensory Physiology at the University of Cambridge, UK.

How the mind works

Sandy Lovie

Cognitive Psychology. By W.A. Wickelgren. Pp.436. (Prentice-Hall: Englewood Cliffs, New Jersey and Hemel Hempstead, UK, 1979.) £11.

THIS is the latest offering from the ever flowing pen of one of the leading lights in human information processing and cognition. In a (relatively) brief compass Wickelgren deftly sketches in most of the live areas and issues of this loosely articulated and most exciting area of psychology. From such traditional areas as perception (both visual and auditory), imagery and attention, thinking, reading and long- and short-term memory, to the more novel topics of semantic memory, Wickelgren has assembled a most persuasive body of evidence to support his modest contention that "Cognitive psychology is concerned with the general principles of how the mind works". Moreover Wickelgren's ability to synthesise material and to disambiguate the closely argued efforts of most of today's brightest workers gives the reader the exciting and restless feeling of being the edge of current knowledge (fe references are earlier than 1960, most ar from the middle to late 1970s).

Of course, Wickelgren cannot hope t avoid the larger questions hanging over th subject: for example, is it structure *an* process or structure *or* process; is it a happening in here or out there; what abo the issues of application and ecologic validity; how far can we push the comput analogy? Perhaps it is inappropriate to as so committed a member of the cognitic club to bother too much about these issues as their lengthy (and usually ponderous) consideration tends to spoil the fun in describing the experimental infighting. But these problems are neither trivial nor vacuous simply because of their low rating on the excitement scale.

Three final points: the chapter objectives and summaries are useful both for insightful and memorial purposes; thank God for the lack of references to Thomas Kuhn, paradigms, normal science, and so on; please when can we have a paperback version for our impoverished students? ☐

Sandy Lovie is Lecturer in Psychology at th University of Liverpool, UK (Acting Hea 1979-80).

Behaviour of experimental animals

B.J. Sahakian

Animal Behaviour in the Laboratory. By P. Silverman. Pp.409. (Chapman and Hall: Andover, UK, 1979.) £15; paperback £8.50.

THE author has attempted to write a simple, informative, and interesting account of the methods available for the observation and quantification of the behaviour of experimental animals. The dust-jacket indicates that the text is suitable for use by "second and third year undergraduates studying animal behaviour and psychology; to postgraduates and to industrial research workers in pharmacology and toxicology laboratories". Its 25 chapters cover a range of tests currently used by researchers interested in determining the effects of drugs on behaviour. The tests include those for the investigation of both conditioned and unconditioned behaviours, and the emphasis is on the behaviour of rodents. The chapters are varied and discuss such topics as ethics, experimental design, physiological psychology, drug screening, central nervous system pharmacology, motor activity, exploratory behaviour, self-administration of drugs and brain stimulation, classical and operant conditioning, and social behaviour.

Although there are some excellent texts for the expert or the advanced student in this area, this book could possibly fill a need for the beginning student or the worker in industrial pharmacological or toxicological research wanting to acquire behavioural skills. Unfortunately, however, though the author has chosen his topics well, their treatment is disappointing. The style of writing is sometimes vague and often lapses into homespun philosophy, where opinions are not substantiated by reference to published research. This tendency is irritating when such important issues as the widespread abuse of barbiturates as sleeping-pills in the UK is discussed for example, page 37. In general, the text could be supplemented by more references, particularly in certain chapters (e.g. chapter 11) to work done after 1970.

Balancing these faults, the summaries at the ends of most chapters are clear and concise, and the different indices (General, Chemicals, Species, and Author) are a useful feature. Finally, it is obvious that the author has a sincere concern for ethical standards in procedures used with experimental animals, a matter of considerable relevance for a general audience. ☐

B.J. Sahakian is a Research Scientist at the MRC Dunn Nutrition Unit, University of Cambridge, UK.

STUDENTSHIPS

THE GRASSLAND
ESEARCH INSTITUTE

Hurley, Maidenhead
Berkshire SL6 5LR
el: Littlewick Green 3631

POST-GRADUATE STUDENTSHIP

ations are invited for a research tship, funded by the Agricultural ch Council, in the Forage Conserv- Section of the Agronomy Division, eriod of three years commencing on ber 1980.

e student will undertake research into er the factors affecting nutrient loss ing the conservation of grass and forage s as silage or the chemistry and micro- ogy of the aerobic deterioration of .

e former project will involve experi- al work with farm-scale silos and puter-based studies.

plicants should have, or expect to ain, a first or upper second class urs degree in agricultural science, ultural engineering, microbiology, or d subjects.

e student will be located at the ute, and will register for a higher e at the University of Reading.

plications by 31 March to the onnel Officer, The Grassland arch Institute, Hurley, Maidenhead, kshire, from whom further details may btained. 4529(F)

UNIVERSITY COLLEGE of Wales, berystwyth. Studentships available for Sc course in solid state chemistry. A one ar full-time interdisciplinary course of udy combining lectures, tutorials, ctical work and a research project. The urse, which has developed close links th UK industry, specialises in the ucture, preparation, characterization d properties of non-metallic materials d prepares graduates for employment in wide variety of industries dealing with mi-conductors, polymers, catalysts, asses etc. Applications are invited from onours graduates, final year students and rsons currently in employment within the eas of chemistry, physics, materials ience and geology. Industrially onsored persons can take this course over o years with three months residence per ar. Write for further information and/or arrange a visit to: Admissions Tutor raduate Studies) Edward Davies mical Laboratories, University College ales, Aberystwyth SY23 1NE.
4502(F)

UNIVERSITY OF WARWICK

Postgraduate Research in Environmental Microbiology and Biochemistry

pplications are invited for research udentships leading to the degree of PhD, the Department of Environmental ences. Science Research Council-CASE rds are currently available for projects the growth of stable mixed microbial ures on chlorinated compounds; rowth of rhizosphere microbial mmunities and their relationship with lant roots; physiology of sulphur bacteria volved in the breakdown of sulphide inerals; and the role of microbial lymers in soil aggregation. Further ojects on NERC, SRC and MRC grants y also be available.

Further particulars and application rms may be obtained from Professor D P elly, Department of Environmental ciences, University of Warwick, Coventry V4 7AL, quoting Ref No PG/1/80.
4536(F)

THE UNIVERSITY OF LEEDS

SRC CASE STUDENTSHIP

'Control of neurotransmitter release'

Applications are invited from graduates with a good honours degree for an SRC CASE Studentship to be held in the Department of Pharmacology in conjunction with ORGANON LTD. from September 1980. The project will be supervised by DR I E Hughes and will involve an investigation of the mechanisms controlling release of radiolabelled neurotransmitters from superfused brain slices. Organon may supplement the normal SRC studentship and will pay additional expenses when the student works in Organon Research Laboratories in Oss (Holland) and Newhouse (Scotland).

Applications, including curriculum vitae, should be sent to Dr I E Hughes, Department of Pharmacology, Worsley Medical and Dental Building, University of Leeds, Leeds LS2 9JT (Tel. (0532) 31751 Ext 7435) by 30 March 1980. 4514(F)

UNIVERSITY OF ABERDEEN

Faculty of Medicine

RESEARCH STUDENTSHIPS

Applications are invited from recent first or upper second class honours graduates in a biological science subject, and from those who expect so to graduate in 1980, for research studentships established by the Faculty of Medicine from its Medical Endowment Funds. Successful applicants will study for the degree of PhD on an approved project in one of the Departments of Anatomy, Biochemistry, Obstetrics and Gynaecology, Pathology, Pharmacology, Physiology or Surgery, commencing in October 1980.

The value of the studentship is £1,820 pa (for students living away from home) with payment of tuition fees and other allowances.

Application forms and further particulars of the projects may be obtained from Helen E Cunningham, University Office, Regent Walk, Aberdeen AB9 1FX to whom applications should be submitted by 21 March 1980. 4527(F)

COURSE

UNIVERSITY OF LONDON
Royal Postgraduate Medical School

MSC DEGREE COURSE IN EXPERIMENTAL PATHOLOGY (TOXICOLOGY)

Applications are invited for the above, one-year, full-time course which is being offered from 1 October 1980.

Applicants should possess a first degree in medicine, veterinary medicine or appropriate science subjects.

A limited number of MRC course studentships will probably be available.

Further details and application forms are available from: School Office (MSc), Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS. Telephone: 01 743 2030 ext 351. Closing date for applications: Friday 30 May 1980. 4530(D)

WORKSHOP

CSH

COLD SPRING HARBOR LABORATORY

WORKSHOP ON

FORMS OF MICROTUBULAR ORGANIZATION IN CELLS

MAY 14 – MAY 17, 1980

G. Albrecht-Buehler, Cold Spring Harbor Laboratory
R. G. W. Anderson, The University of Texas

The workshop will focus on biochemical, morphological and functional aspects of microtubules in eukaryotes through presentations by invited speakers and follow up discussions and poster sessions.

Abstracts are invited to be submitted for the poster sessions by March 28.

Further information, registration and abstract forms can be obtained by contacting:

Mrs. Gladys Kist, Meetings Secretary
Cold Spring Harbor Laboratory
P. O. Box 100
Cold Spring Harbor NY 11724

COURSE

EMBO COURSE ON MEMBRANE BIOGENESIS

October 5-15, 1980
European Molecular Biology Laboratory
Heidelberg, F.R.G.

The course will be organized by the Membrane Group at EMBL and will comprise a series of lectures (6-8 October) and practical work (9-15 October).

The teaching staff will include:

G. Blobel (USA), N. Crawford (UK), N. Le Douarin (France), C. de Duve (USA), C. G. Gahmberg (Finland), G. Gerisch (F.R.G.), V. Herzog (F.R.G.), E. Lazarides (USA), J. Meldolesi (Italy), W. Neupert (F.R.G.), B. Pearse (UK), D. Sabatini (USA), R. Schekman (USA), J. Slot (Netherlands), M. Schwartz (France) and R. Steinman (USA).

and the following staff members of EMBL:

B. Dobberstein, H. Garoff, G. Griffiths, A. Helenius, B. M. Jockusch, D. Louvard, H. Reggio, K. Simons, G. Warren, H. Weiss and P. Wingfield.

Practical work will include: Membrane assembly in vivo and in vitro; Intracellular transport of membrane proteins; Biogenesis of cell polarity; Endocytosis and membrane recycling; Immunofluorescent microscopy and electron microscopy of the cytoskeleton.

A maximum of 36 students will be allowed to attend. Students will be allowed to pursue one of the courses above, but in their application they should also indicate which of the other topics is an acceptable alternative. Applications should include a short curriculum vitae and a description of present research interests.

Applications should be sent to: Henrik Garoff, Postfach 10.2209, D-6900 Heidelberg, F.R.G.

The closing date for applications is May 31st, 1980.

LIQUID SCINTILLATION CHEMICALS

We're at Your Service More Than Ever Before.

Our sales, service, and technical assistance have never been stronger in Europe. As a result you can expect immediate response from the NEN office in your country, and fast delivery of the products you need from the world's most widely referenced selection of liquid scintillation chemicals.

If you need technical assistance, you will find that our people are exceptionally well equipped to provide it. But if they don't have the answer, the director of our LSC Applications Laboratory, Dr. Yutaka Kobayashi, will help you.

In short, we're doing everything to meet the rapidly increasing demand for NEN liquid scintillation chemicals in Europe—with an expanded technical sales force, locally available products, and fast response to technical questions.

We look forward to your call.
